Among the Contributors of New Articles to the Third Volume of the Revised Edition are the following :

WILLARD BARTLETT.

BOMBAY.
BORNEO.
BURMAH.
CALCUTTA.

Prof. C. W. BENNETT, D.D., Syracuse University.

BOND, THOMAS EMERSON.
BUNTING, JABEZ.

JULIUS BING.

BONAPARTE FAMILY,
BOSSUET,
BUNSEN, BARON VON,
and other articles in biography and geography.

DEHAVAN BLOODGOOD, M.D., U. S. N.
BUCHANAN, FRANKLIN.

FRANCIS C. BOWMAN, Esq.

BOYCE, WILLIAM.
BRAHMS, JOHANNES.

WILLIAM T. BRIGHAM, Esq., Boston.

BREADFRUIT,
BUCKTHORN,
and other botanical articles.

EDWARD L. BURLINGAME, Ph. D.

BOTHWELL, EARL OF,
BRASIDAS,
and articles in history and biography.

W. BRYAN CLARK, Springfield, Mass.
BOWLES, SAMUEL.

Prof. E. H. CLARKE, M.D., Harvard University.

BROMIDES,
CALABAE BEAN,
CALOMEL,
CAMPHOR,
and other articles of materia medica.

HON. T. M. COOLEY, LL. D., Ann Arbor, Mich.

BOND,
BRIBBEY,
CABINET,
and other legal articles.

Prof. J. C. DALTON, M. D.

BOTALLI, LEONARDO,
BRAINARD, DANIEL,
BRIGHT, RICHARD,
CANCER,
CAPILLARY VESSELS,
and various medical and physiological articles.

EATON S. DRONE.

BOSTON, MASS.,
BROOKLYN, N. Y.,
CALIFORNIA,
CAMBRIDGE, MASS.,
and other articles in American geography.

B. A. FINKELSTEIN.

BULGARIA.

BOLAN PASS

BOLAN PASS, a defile in the mountains of N. E. Beloochistan, between Dadur and Shawl, on the route between the lower Indus and the table land of Afghanistan. It consists of a succession of ravines rising 90 ft. to the mile for 55 m., when the summit is reached at a height of 5,793 ft. above the level of the sea.

Bolan Pass.

A small stream called the Bolan river flows down the pass, and after rains is a dangerous torrent. The British expedition to Afghanistan in 1839 spent six days, from March 16 to 21, in passing through this defile.

BOLAS, a missile weapon in common use among the Indians on the great South American plains, and especially among the gauchos of the Argentine Republic, chiefly used for capturing animals. It consists of two balls covered with leather, and united by a thin plaited thong

BOLE

varying in length from 6 to 8 feet. The gaucho holds one of the balls in his right hand, whirls the other round his head, and when sufficient momentum has been obtained sends them whirling like chain shot through the air. Striking the legs of an animal, the thong is tightly wound about them, rendering escape impossible. This weapon has often been used with great effect in war. The balls may be of stone, iron, or wood; those of iron, usually small, may be projected an amazing distance.

BOLBEC, a town of France, in the department of Seine-Inférieure, on the Bolbec river, 16 m. E. N. E. of Havre; pop. in 1866, 9,063. The ample water power furnished by the river Bolbec makes it a thriving manufacturing town. Its principal productions are cotton fabrics, but it has also woollen and linen factories, dye works, and tanneries.

BOLE (Gr. βόλος, a mass), an argillaceous earthy mineral which occurs in amorphous masses of various colors, as yellow, black, brown, and bright red, all derived from oxide of iron. The substance is probably disintegrated basalt. It has a conchoidal fracture, yields to the nail, and the streak is shining. When placed in water it absorbs it rapidly, and falls to powder. It was formerly employed as a medicine for its absorbent, astringent, and tonic properties; the last due, no doubt, only to the iron in its composition. It is still used in India in medicine, and in Europe for giving a color to anchovies and tooth powders, and as a medicine in veterinary practice. Analysis shows it to be a hydrous silicate of alumina, with varying proportions of oxide of iron, and very small quantities of lime and magnesia. It is used as food by some of the native Indians of South America, and the Japanese eat it to induce a thin and spare habit of the body. In Germany bole is calcined, washed, and ground for a paint, and employed to remove grease stains from cloth or wooden floors, and hence called *Bergseife*, mountain soap. The paint known as sienna, or burnt sienna, is a prepara-

tion of a chestnut-brown variety from Siena in Italy. It is fashioned into pipes by the North American Indians, Turks, and Germans.

BOLEYN, Anne. See **ANNE BOLEYN**.

BOLEGRAD, a town of Roumania, in the province of Moldavia, at the head of Lake Yalpuh, connected with the mouths of the Danube, 105 m. S. S. E. of Jassy, and 28 m. N. N. W. of Ismail; pop. in 1866, 9,114. The inhabitants are chiefly Bulgarians. The houses are nearly all of stone. The town was formerly included in the Russian province of Bessarabia, but was ceded to Moldavia in 1857, in conformity with the Paris treaty of the preceding year.

BOLINGBROKE, Henry St. John, viscount, an English statesman and author, born at Battersea, London, Oct. 1, 1678, died Dec. 12, 1751. He was the son of Sir Henry St. John, bart., and of a daughter of the earl of Warwick. His early education was managed by his mother, on strict puritanical principles. After attending school at Eton, he proceeded to Christ Church college, Oxford, where he distinguished himself by the brilliancy of his parts rather than by diligence. After a tour on the continent in 1698-'9 he was married in 1700 to Frances, daughter of Sir Henry Winchcomb; but the union was unhappy, and they speedily separated. St. John's varied attainments and personal attractions rendered him a favorite in the fashionable circles of London, and before he was 25 years of age he was a notorious libertine. In the hope of interesting him in honorable pursuits, his father retired from the position of representative in parliament for the borough of Wootton Bassett, which was transferred to him, and he was thus brought into conspicuous public life. The Tories, under the lead of Rochester and Godolphin, were then in power, and St. John at once attached himself to them. In 1704 he entered the ministry as secretary at war, and for four years he discharged the duties of that office. When Godolphin became a Whig, and with Marlborough formed a new ministry, St. John retired to the country, and devoted himself to study. Two years later the Tories triumphed, and he was made secretary of state in the department of foreign affairs. In 1712 he was called to the house of lords with the title of Viscount Bolingbroke. Soon after the conclusion of the peace of Utrecht, in the negotiation of which he took an active part, a violent dissension broke out between him and his old friend Harley, then lord high treasurer and earl of Oxford, which did not terminate till Queen Anne had dismissed Oxford and made St. John her prime minister. The queen died a week later, and George I. dismissed him, as he was suspected of having plotted for the return of the Stuart family to the throne. He fled in disguise to France, and became titular prime minister to the pretender, James III. During his absence he was impeached by Walpole at the bar of the house of lords, and formally attainted. After the failure of the pretender's Scottish

expedition Bolingbroke was dismissed for neglect. He then sought a reconciliation with the Hanoverian party, but Walpole procured the prolongation of his exile, and for seven years he remained in banishment, residing principally at La Source, near Orleans, and devoting himself to belles-lettres and an active correspondence with Pope, Swift, and other literary contemporaries. His wife dying in 1718, he was privately married two years later to the widow of the marquis de Villette, a niece of Mme. de Maintenon. It was chiefly through her instrumentality, in bribing the duchess of Kendal, a mistress of King George, with the sum of £11,000, that he gained permission to return to his own country in 1723. He recovered his property, but being still excluded from the house of lords, he began writing political papers in the "Craftsman," under the titles of "An Occasional Writer" and "Humphrey Oldcastle," in which he attacked the ministry. His "Letters upon English History" and his "Dissertation upon Parties" formed parts of this series. Failing in his efforts to overthrow the ministry, he quitted England once more for France, in 1735 and remained abroad till the death of his father in 1742, when he returned to take possession of the family estate at Battersea. He passed his leisure in the preparation of his literary works, and in intercourse with his philosophic and literary friends, among whom were numbered many of the most eminent men then living. On his death he bequeathed his manuscripts and works to David Mallet, who published a complete edition of them, in 5 vols. 4to, in 1754. A new edition, with a life by Goldsmith, appeared in 1809, in 8 vols. 8vo. Among the most noteworthy of his writings, besides those already noticed, are "The Idea of a Patriot King," a "Letter on the Spirit of Patriotism," "Some Reflections on the Present State of the Nation," "Letters on the Study and the Use of History," and "Concerning Authority in Matters of Religion." They are written in a fluent, flexible, and eloquent style, combining an apparently profound philosophy with a sprightly and careless wit; but the rhetoric is sometimes artificial, the learning borrowed, and the thought unimportant. In spite of their serious defects, however, his writings for a long time influenced the tone of thought as well as the manner of writing of his age, and will ever occupy a distinguished place in the literary history of that epoch. As an orator, Bolingbroke held a high rank, but no complete specimen of his eloquence is now extant.

BOLINTINEANO, Demeter, a Roumanian poet, born at Bolintina, near Bucharest, in 1826. He early entered the public service, and soon afterward published in the newspapers of Bucharest several poems and articles which offended the government and caused him to lose his official position. The party of opposition, however, saw a valuable adherent in Bolintineano, and furnished him the means of studying in Paris,

whither he went in 1847. In 1848, on the outbreak of the Wallachian revolution, he returned, and edited the *Populul suveranu*, the organ of the democratic party. On the downfall of the revolutionary government he again went to Paris, and afterward to Turkey. Under the government of Prince Cuza, he found himself again at liberty to return to Bucharest, where he once more took an active part in political affairs through the journal *Dimbovitia*. After Prince Cuza's *coup d'état* (1864), Bolintineanu received a place in the cabinet, but preferred to exchange it for the office of councillor of state. His principal poetical works, collected and published in 1852, consist of lyrics and ballads on themes connected with his country (French translation by himself, *Brises d'Orient*, 1866). He has also published a romance entitled *Manilu*, which has attained much celebrity, and other prose works.

BOLIVAR, a W. county of Mississippi, separated from Arkansas by the Mississippi river; area, about 800 sq. m.; pop. in 1870, 9,732, of whom 7,816 were colored. It consists mainly of swamp land, part of which is subject to frequent inundations. The climate of the low lands is unhealthy, and extensive fertile tracts are consequently left uncultivated. The chief productions in 1870 were 182,728 bushels of Indian corn and 15,571 bales of cotton. There were 720 horses, 1,478 mules and asses, 1,414 milch cows, 3,099 other cattle, and 4,871 swine. Capital, Beulah.

BOLIVAR Y PONTE, Simon, the liberator of Colombia, born in Carácas, July 24, 1783, died at San Pedro, near Santa Marta, Dec. 17, 1830. He was the son of one of the *familias Mantuanas*, which then constituted the creole nobility in Venezuela. He was sent to Madrid to be educated, married there in 1801, and returned to Venezuela, where on his arrival his wife died of yellow fever. He visited Europe a second time, but in 1809 returned home by way of the United States, and after the revolution broke out at Carácas, April 19, 1810, accepted a mission to London to purchase arms and solicit the protection of the British government. In September, 1811, he joined the insurgents, was made lieutenant colonel on the staff of Gen. Miranda, and received the command of Puerto Cabello, the strongest fortress of Venezuela. The Spanish prisoners of war confined in the citadel of Puerto Cabello, 1,200 in number, having succeeded in overcoming their guards and in seizing the citadel, Bolivar evacuated the place and retired to his estate at San Mateo, and the fortress was immediately occupied by the Spaniards under Monteverde. This event obliged Miranda, on the authority of the congress, to sign the treaty of Vitoria, July 25, 1812, which restored Venezuela to the Spanish rule. Miranda endeavored to leave the country, but was arrested in the night at La Guayra by Bolivar and other officers, and surrendered to Monteverde, who despatched him to Cadiz, where after some

years' captivity he died in irons. Bolivar now went with his cousin Ribas to Cartagena, and enlisted there, from a number of refugees, 800 soldiers for an expedition against the Spaniards in Venezuela. To this force Manuel Rodriguez Torices, the president of Cartagena, added 500 men under the command of his cousin, Manuel Castillo. The expedition started in the beginning of January, 1813; and although Castillo suddenly decamped with his grenadiers, Bolivar kept on up the river Magdalena, driving the Spanish royalists from Tenerife, Mompox, and Cucutá, and arrived at Bogotá, at that time the seat of the congress of New Granada. Here Bolivar and Ribas were both made generals by the congress, and, after having divided their little army into two columns, they marched by different routes upon Carácas, gaining recruits at every step. The only serious resistance on the part of the Spaniards was directed against the column of Ribas, who however routed Gen. Monteverde at Los Taguanes, and forced him to shut himself up in Puerto Cabello with the remainder of his troops. On hearing of Bolivar's approach, Gen. Fierro, the governor of Carácas, sent deputies to propose a capitulation, which was concluded at Vitoria; and on Aug. 4, 1813, the liberating army entered the capital. Bolivar was honored with a public triumph, and having proclaimed himself "dictator and liberator of the western provinces of Venezuela"—Mariño had assumed the title of "dictator of the eastern provinces"—he created "the order of the liberator," established a body guard, and surrounded himself with the show of a court. By the conduct of his officers and by the suspicions which were prevalent that Bolivar aimed only at personal aggrandizement, the enthusiasm of the people was turned to dissatisfaction. The Spaniards recovered themselves and resumed the offensive. Jan. 1, 1814, Bolivar assembled a junta of the most influential inhabitants of Carácas, and asked to be relieved of the dictatorship; but the junta insisted that he should retain the supreme power. In June, 1814, the Spanish general Boves marched on La Puerta, where Bolivar and Mariño had formed a junction, and defeated them in a battle in which the patriots lost 1,500 men. Carácas was next taken, and Bolivar, defeated again at Aragua, fled to Cumaná, sailed with some of his officers to Cartagena, and thence went to Tunja, where the congress of the federal republic of New Granada created him commander-in-chief, with the double mission of forcing the president of the province of Cundinamarca to acknowledge the authority of the congress, and of then marching against Santa Marta, the only fortified seaport the Spaniards still retained in New Granada. He took Santa Fé, carrying the suburbs by storm, and Bogotá immediately capitulated and became the seat of the general government of New Granada. In his design against Santa

Marta he was hindered by the refusal of Castillo, the commander of Cartagena, to furnish the munitions of war ordered from the citadel there. Bolivar led his troops against Cartagena in the hope of reducing Castillo to submission, and the season for action against the Spaniards was wasted by an indecisive siege of that city which lasted until May. Meanwhile a great Spanish expedition from Cadiz had arrived, March 25, 1816, under Gen. Morillo, at the island of Margarita, and had been able to throw powerful reinforcements into Santa Marta, and soon after to take Cartagena itself. Previously, however, Bolivar, seeing the hopelessness of the struggle there, had embarked for Kingston, Jamaica, with about a dozen of his officers, on an armed English brig. During his eight months' stay at Kingston Morillo was overrunning New Granada almost without opposition; but the generals Bolivar had left in Venezuela, and Gen. Arismendi in the island of Margarita, still held their ground against the Spanish arms. From Kingston Bolivar repaired to Port-au-Prince, where, on his promise of emancipating the slaves, Pétion, the president of Hayti, offered him four negro battalions for a new expedition against the Spaniards in Venezuela. At Cayes he met Brion, who had sailed from London with a corvette, arms, and stores for the republicans, and some patriot refugees from Cartagena. Having united these forces, he sailed for Margarita April 16, 1816, to aid Arismendi, who had already reduced the Spaniards to the single spot of Pampatar. On Bolivar's formal promise to convoke a national congress in Venezuela as soon as he should be master of the country, Arismendi summoned a junta in the cathedral of La Villa del Norte, and publicly proclaimed him the commander-in-chief of the republics of Venezuela and New Granada. On June 1, 1816, Bolivar landed at Carupano, but here Mariño and Piar separated from him to carry on a war against Cumaná under their own auspices. Weakened by this separation, he set sail for Ocumare with 18 vessels, of which 7 only were armed. His army mustered but 650 men, swelled by the enrolment of negroes, whose emancipation he had proclaimed, to about 800. While advancing toward Valencia with this force, he was attacked and defeated by the Spanish general Morales not far from Ocumare. Compelled to reembark, he went first to the small island of Buen Ayre, and afterward joined the other commanders on the coast of Cumaná; but being harshly received, he quickly retraced his steps to Cayes. After some months a majority of the Venezuelan military chiefs recalled him as their general-in-chief. He went first to Margarita with the arms, munitions of war, and provisions supplied by Pétion, and was joined Jan. 2, 1817, by Arismendi; but five days later, when Arismendi had fallen into an ambush laid by the Spaniards, Bolivar escaped to Barcelona. The troops rallied at the

latter place, whither Brion sent him guns and reinforcements, so that he soon mustered a new corps of 1,100 men. Here on Feb. 16 he met the Spanish forces under Morillo and defeated them, after an obstinate battle lasting three days. On April 5 Bolivar left Barcelona, and on the 15th the town was taken by the Spaniards and the garrison slaughtered. Piar, a man of color and native of Curaçao, designed and executed the conquest from the Spaniards of the provinces of Guiana, Admiral Brion supporting that enterprise with his gunboats. On July 20, the whole of the provinces being evacuated by the Spaniards, Piar, Brion, Zea, Mariño, Arismendi, and others, assembled a provincial congress at Angostura, and put at the head of the executive a triumvirate, of which Bolivar was appointed a member, notwithstanding his absence. On these tidings Bolivar went to Angostura, and, supported by Brion, dissolved the congress and the triumvirate, to replace them by a "supreme council of the nation," with himself as the chief, and Brion and Antonio Francisco Zea as the directors, the former of the military, the latter of the political section. Piar was arraigned on a charge of conspiracy before a war council under the presidency of Brion, convicted, and shot, Oct. 16, 1817. The conquest of Guiana was a great aid to the patriots; and a new campaign, announced by Bolivar through a proclamation, was generally expected to result in the final expulsion of the Spaniards. Nevertheless, toward the end of May, 1818, he had after several battles lost all the provinces lying on the northern side of the lower Orinoco, while on the affluents of the upper, Paez, the leader of the patriot *llaneros*, was constantly victorious. At this critical moment he met with Santander, a native of New Granada, and furnished him with the means of invading that territory, where the population were prepared for a general rise against the Spaniards. Powerful succor in men, vessels, and munitions of war began to arrive from England, and English, French, German, and Polish officers flocked to Angostura. Finally Bolivar was induced to convene a national congress, Feb. 15, 1819, the mere name of which proved powerful enough to create a new army of about 14,000 men, so that he found himself enabled to resume the offensive. He now formed the plan of making a feint toward Carácas, and, when Morillo should have concentrated his forces in Venezuela, suddenly turning to the west, uniting with Santander's guerillas, and marching upon Bogotá. To execute this plan, he left Angostura Feb. 24, 1819, made a most extraordinary march across the Andes, and, aided by Santander and the foreign troops, consisting mainly of Englishmen, decided the fate of New Granada by repeated victories in July and early in August in the province of Tunja. On Aug. 10 Bolivar made a triumphal entry into Bogotá, amid the acclamations of the inhabitants, who hailed him as their libe-

rator. The Spaniards, all the Granadian provinces having risen against them, shut themselves up in the fortified town of Mompox. Having regulated the Granadian congress at Bogotá, and installed Gen. Santander as commander-in-chief, Bolivar marched to Montecal in Venezuela, where he had directed the patriot chieftains of that territory to assemble with their troops. Morillo withdrew before Paez from San Fernando de Apure to San Carlos. In October, 1819, the congress of Angostura had forced Zea, whom Bolivar had made vice president during his absence, to resign his office, and chosen Arismendi in his place. On receiving this news, Bolivar suddenly marched his foreign legion toward Angostura, surprised Arismendi, exiled him to the island of Margarita, and restored Zea to his dignities. On Dec. 17, 1819, the two republics of Venezuela and New Granada at a general congress united under the name of Colombia, and Bolivar was made president. In New Granada 15 provinces out of 22 had joined the government of Colombia, and the Spaniards now held there only the fortresses of Cartagena and the isthmus of Panama. In Venezuela six provinces out of eight obeyed the laws of Colombia. Such was the state of things when Bolivar entered into negotiations with Morillo, resulting, Nov. 25, 1820, in the conclusion at Truxillo of a truce for six months. On Dec. 17 Morillo embarked at Puerto Cabello for Spain, leaving the command-in-chief to Miguel de la Torre. On June 24, 1821, Gen. La Torre was totally defeated by Bolivar and Paez at Carabobo, about half way between San Carlos and Valencia. In this battle the royalists lost 6,000 men and all their baggage and artillery, and by it the war in Venezuela was virtually concluded. La Torre fled to Puerto Cabello, where he shut himself up with the remainder of his troops. On Sept. 23 Cartagena capitulated to Santander, and Puerto Cabello was captured by Paez in November, 1823. The Colombian congress, opened in May, 1821, at Cucutá, published on Aug. 30 a new constitution, and after Bolivar had again resigned, renewed his powers. Having signed the new constitution, he obtained leave to undertake the campaign of Quito (1822), to which province the Spaniards had retired after their ejection from the isthmus of Panama. This campaign ended in the incorporation of Quito, Pasto, and Guayaquil into Colombia. Gen. San Martin, the liberator of Peru, having asked the assistance of Bolivar in driving the Spaniards from that country, he left the government in the hands of the vice president Santander, marched upon Lima, which the royalists evacuated at his approach, entered the city in triumph Sept. 1, 1823, and on Feb. 10, 1824, was made dictator by the congress of Lima. With 6,000 Colombians under Gen. Sucre and 4,000 Peruvians under Gen. Miller, he crossed the Andes, and on Aug. 6, 1824, defeated the Spanish army on the plains

of Junin. He then returned to Lima to reorganize the government, leaving Gen. Sucre to follow the retreating royalists to Upper Peru, where on Dec. 9 he achieved the decisive victory of the war at Ayacucho. Bolivar convened a congress and resigned the dictatorship of Peru, Feb. 10, 1825. The provinces of Upper Peru met in convention at Chuquisaca, and having assumed for their country the name of Bolivia they made Bolivar perpetual protector, and asked him to prepare for them a plan of government. He returned to Lima, and from there on May 25, 1826, presented the Bolivian code to the congress of Bolivia. In the mean time a serious antagonism had broken out in Colombia between the centralists or Bolivarists and the federalists, Paez, the vice president of Venezuela, having broken into open revolt. Bolivar went to Bogotá, assumed dictatorial powers Nov. 23, 1826, and meeting Paez at Puerto Cabello the last of December, he not only confirmed him in his command of Venezuela, and issued a proclamation of amnesty to all the rebels, but openly took their part. Bolivar and Santander were reelected president and vice president; but in February, 1827, the former wrote a letter to the senate declining the position. A large minority were in favor of accepting his declination, but his friends proving a majority, he was induced to withdraw it. He repaired to Bogotá to take the oath, but before doing so issued a decree, March 21, 1828, convoking a national convention at Ocaña, with a view to modify the constitution in favor of the executive power. When, however, a large majority declared against the proposition, his friends vacated their seats, by which proceeding the body was left without a quorum, and thus became extinct. From a country seat some miles distant from Ocaña, to which he had retreated, he published a manifesto attacking the convention and calling on the provinces to recur to extraordinary measures. Popular assemblies at Carácas, Cartagena, and Bogotá anew invested him with dictatorial power. An attempt was now made to assassinate him in his sleeping room at Bogotá, which he escaped only by leaping in the dark from the balcony of the window, and lying concealed under a bridge. Santander, convicted of taking a part in the conspiracy, was banished, and Gen. Padilla on the same charge was condemned to death. Violent factions disturbing the republic in 1829, Bolivar in a new appeal to the citizens invited them to frankly express their wishes as to the modifications to be introduced into the constitution. An assembly of notables at Carácas answered by denouncing his ambition, declaring the separation of Venezuela from Colombia, and placing Paez at the head of that republic. The senate of Colombia stood by Bolivar, but other insurrections broke out at different points. Having resigned for the fifth time, in January, 1830, he again accepted the presidency, and left Bogotá to wage war on Paez in the name of the

Colombian congress. But the influence of his friends in the congress was now weak, and he was forced to tender his resignation, notice being given that an annual pension would be granted to him on the condition of his departure for foreign countries. He accordingly sent his resignation to the congress, April 27, 1830, but prolonged his sojourn at San Pedro until the end of the year, when he suddenly died. A few days before his death he dictated a farewell address to the nation, complaining bitterly of the ingratitude of those to whom he had devoted his life and fortune. During his whole life Bolivar was never without malignant enemies, and he was constantly charged with cowardice and an ambition which aimed only at his own aggrandizement. But amid the conflicting reports of his biographers these facts stand forth strongly in his favor: that he conquered the independence of three states and secured their recognition by other nations; that he gave them laws which secured the better administration of justice; and that he died no richer from having had the control of the treasures of Colombia, Peru, and Bolivia, and expended nearly all his own large fortune in the people's service. He was fond of pleasure, fame, and power, but patriotism and love of freedom were his ruling passions; and his energy, generosity, and endurance in misfortune were acknowledged even by his enemies. By decree of the congress of New Granada, his remains were removed in 1842 to Carácas, where a monument was erected in his honor; and in 1858 the city of Lima erected an equestrian statue of the "Liberator of the Peruvian Nation."

BOLIVIA, a republic of South America, lying between lat. 12° and 24° S., and lon. 57° 25' and 70° 30' W., bounded N. and E. by Brazil, from which it is partly separated S. E. by the river Paraguay, S. by the Argentine Republic and Chili, and W. by the Pacific ocean and Peru. Bolivia, however, claims that portion of the Gran Chaco comprised between the rivers Paraguay and Bermejo, which would extend its southern limits to lat. 26° 53' S. The republic is divided into nine departments, which, with their areas, capitals, and population in 1865, are as follows:

DEPARTMENTS.	Area.	Populat'n.	CAPITALS.	Populat'n.
Atacama.....	70,178	7,948	Cobija.....	2,500
Beni.....	150,000	54,000	Trinidad.....	4,835
Chuquisaca.....	72,798	219,788	Sucre.....	26,664
Cochabamba.....	26,803	879,788	Cochabamba.....	44,908
La Paz.....	48,051	519,465	La Paz.....	88,092
Oruro.....	21,600	111,818	Oruro.....	8,492
Potosi.....	54,297	290,804	Potosi.....	25,774
Santa Cruz.....	144,077	144,684	Santa Cruz.....	11,736
Tarja.....	114,484	108,800	Tarja.....	8,875
Total.....	677,288	1,881,585		

The departments are subdivided into 37 districts, and these into 45 provinces. No official survey of the country has ever been made, but the above areas are, with the exception of the

department of Beni, according to a map of Bolivia published in 1859 by Lieut. Col. J. Ondarza. Behm gives only 535,747 sq. m. as the total area; but the former is probably more correct. The population consists of native whites, for the most part descendants of the Spanish settlers, mestizoes or Cholos (mixed white and Indian), mulattoes, zambos (mixed Indian and negro), Indians in a domesticated state, and savage Indians. Of the last there are about 250,000, which added to the figures of the table gives a total population of 2,081,585, rather more than one fourth of whom are whites. The aboriginal is by far the most numerous element in the republic; it forms in the province of La Paz nine tenths of the population; in that of Tarja it is five times as numerous as the white. Of the many aboriginal tribes still existing in Bolivia, the most noteworthy are the Aymarás or Aymarús, Quichuas, Moxos, and Chiquitos. The first two, once united under the dominion of the incas, speak languages of kindred origin, while in their customs and manners little dissimilarity is noticeable. The Aymarás dwell chiefly in La Paz, although some are met with in Oruro; and the Quichuas inhabit the coast, the valley of the Desaguadero, and the N. and E. portions of the republic. Various monuments, such as obelisks, burial places, and other ruins, attest the proficiency in art and the high degree of civilization attained by the Aymará nation at an epoch far anterior to that of the incas. The Moxos (or Mojos) are remarkable for their ingenuity. The language of the Chiquitos is copious and flexible, and has a special vocabulary for females. The hair of this people does not whiten in extreme old age, but grows yellow. Most of these tribes have embraced Christianity and fairly entered upon the career of civilization. The Guarayos and Siriones are evidently descendants of a mixed race from the early Spanish settlers. In the tracts chosen by the Jesuits for their missions there linger the remnants of numerous indigenous nations, differing in language, customs, and dress. The Bolivian Indians are usually squat in figure, robust and muscular, and capable of enduring the greatest hardship and fatigue; and they are especially remarkable for the rapidity with which they perform long journeys, travelling on foot, at a sort of trot, for days in succession, with no other sustenance than coca leaves chewed with lime or ashes, and occasionally a small quantity of pounded maize. Though usually mild and passive, they sometimes yield to fearful outbursts of temper. All the tribes above mentioned dwell in houses or huts constructed of sun-dried bricks, rushes, or maize stalks thatched with grass. The uncivilized tribes, on the banks of the lower Beni and elsewhere, go naked, preserve the savage customs of their ancestors, lead a roving life, and subsist chiefly on game, wild roots, and fruits. The Spanish creoles are most numerous in the mining districts and in Cochabamba; and im-

migrants into the country since the separation from Spain have chiefly settled in these places and in La Paz. Pure negroes are rarely met with.—On the Pacific Bolivia has a coast line of 250 m. at most, including the sinuosities, which are numerous and of considerable extent. The shore is high and rugged, and in parts interrupted by lofty hills; while to the interior stretches an arid sandy desert, only habitable in narrow strips along the banks of the rivers. The passage across this desert and over the Andes is attended with many hardships; and transportation can only be effected on the backs of mules. In the time of the incas this wilderness was traversed from Peru to Chili by a paved road or path wide enough for a single person to walk on. There is at present but one road leading from the coast to the interior, from Cobija to Oruro. Until 1872 there were but two seaport towns of any importance on the coast. These were Cobija or Lamar, lat. 22° 32' 50", a free port on the bay of Santa Maria Magdalena or Endymion, affording good anchorage for ships of any size, and shelter from the S. winds which prevail here; and Tocopilla, on the bay of Algodonales. But in that year the small town of Mejillones, on the bay of the same name, about lat. 23° S., was very considerably extended, owing to the recent discovery of rich silver mines in the district of Caracoles, equally divided between Chili and Bolivia. By the middle of the year referred to, 24 blocks of 800 feet square had been laid out, and a number of new buildings completed, these having been for the most part constructed on sites given by the government to families moving thither from Cobija, which town, it is supposed, will soon fall into decay after the railway now in process of construction from Caracoles to Mejillones is finished. Poor families received pecuniary assistance to enable them to move. The water at Mejillones is plentiful and excellent; an exception to the rule that on that part of the Pacific coast extending from Paíta in the north of Peru to Valdivia in the south of Chili, water is neither abundant nor good. The bay of Mejillones, or Bahía de la Herradura (Horseshoe bay), S. of Cobija, has eight fathoms of water, and is sheltered by the Morro de Mejillones. North of Cobija bay are several shallow sandy bays with rocky points or promontories; but the most extensive inlet along the coast is Moreno bay (named from Mt. Moreno beside it, about 7,000 ft. high), lat. 28° 29', 17 m. wide, but frequented only by coasters. Between Manina creek and the river Loa are several guano beds, still worked, but showing signs of exhaustion.—The most striking feature of Bolivia is its gigantic mountains. These separate in the southwest portion of the republic, between lat. 21° and 22° S., into two systems, the Cordillera Occidental and the Cordillera Oriental or Cordillera Real, the latter consisting of many lofty ridges. These two great chains unite again to the north in the ridge cluster of Apolobamba,

lat. 14° 35' S. In the W. Cordillera, the following peaks rise beyond the limit of perpetual snow: Tacora, Tatasavaya, Pomarapi (21,700 ft. above the sea level), Parinacocha or Parinacota (22,030 ft.), Guallatiri or Gualatieri (21,960 ft.), Iquimo, Toroni, Yabricoya, and the volcanoes Isluya and Sajama or Sahama (22,350 ft.), this last being, with the exception of Aconcagua, the highest point in the new world. In lat. 21° S. this same chain widens in an easterly direction, presenting a number of snow-covered mountains, especially in lon. 68° 20' and 68° 50'; and still further E., the volcanoes Ollagua, Olca, and Tica. The Cordillera de Lipez, the uniting link between the E. and W. Cordilleras, is mainly composed of snow-capped peaks terminating in slender needle-shaped points. In lat. 22° S. the Cordillera Oriental forms a *nudo*, or ridge cluster, having for its nucleus the Cerro de Chorolque; from which point the Chocaya and the Tasna and Ubina ranges stretch northward in two parallel ridges to lat. 20° S., where they unite at the *portillo* of Guasaco, one of the most elevated passes on the globe. A single chain, Frailes, continues thence to lat. 19° S. Here it takes the name of Cordillera de los Azanaques de Condo, and again breaking off into five distinct branches, terminates in the Nevado de Illimani, the loftiest of whose three summits rises 21,145 ft. above the sea. East of the Cordillera de los Frailes, and in the line of the Tasna and Ubina ridge (also named the Cordillera de Chichas), the great eastern chain forms the Nudo de Potosí y Porco, which is likewise the central point of the *nevados* of the same names. Beyond the limits of the hill country, which extends into the valley of the Río Grande or Guapey to a distance of nearly 400 m. from the coast, lies the great Moxos plain, in which not even a pebble is to be found. During the wet season this region is flooded, and transit by boats is practicable in almost every direction through its dense forests. The country of the Chiquitos is rocky and elevated above the reach of inundation. Between the two great Cordilleras lies the valley of the Desaguadero, a vast inter-alpine plain, with an estimated area of 30,000 sq. m., which from its great elevation—13,340 ft. on an average—and the height of the mountains which surround it, might be called the Thibet of South America. In this table land, which is intersected by isolated hills and low mountain ranges, are Lake Titicaca, and the rich silver and copper mines of Corocoro to the north, while the S. part is mainly covered by a vast, solid, and almost uninterrupted crust of salt many inches thick, and nearly 5,000 sq. m. in extent. Between the mountain ranges stretching eastward toward the great wooded plain are numerous fertile valleys, principal among which is the Valle Grande.—Lake Titicaca, whose waters are divided between Peru and Bolivia, and whose shores were the chief seat of power of the incas, is situated in the table land just referred to. It is the largest inland lake in South America,

its length being variously estimated at from 80 to 120 m., and its average breadth being 40 m. Its surface is dotted with small islands, containing curious ruins. It was on one of these islands, also called Titicaca, that according to the legend Manco Capac and his consort, Mama Oello Huaco, the founders of the inca dynasty, descended to spread civilization through the surrounding nations. Into the lake flow a number of rivers, which during the rainy season are of considerable volume; and much of the water is drained off by the Desaguadero, its only outlet, a navigable river, varying in width from 25 to 60 yards, which, after a southerly course of nearly 200 m., flows into the swampy lake of Aullagas or Paria, whose surface is perhaps 490 ft. lower than that of Titicaca, and which has no visible issue. In Lake Aullagas are two islands, Panza and Filomena, the latter recently discovered. In the department of Beni is Lake Roguaguado, 1,100 ft. above the sea, with an area of about 900 sq. m.; and in a cultivated valley near Potosí is the remarkable Laguna de Tarapaya, situated in a circular basin on a sort of elevated lawn. While the water in the centre is constantly in a state of violent ebullition, the temperature at the brink is only about 98° F. It is said that in 1825, when an inundation rolled over Callao on the Pacific coast, the water disappeared for a time from this lagoon. There are numerous other lakes and marshes in the south and east, from which latter the Chiquito Indians extract copious quantities of salt; but little is yet known of their precise situation and extent. Bolivia is the centre of the watershed between the feeders of the Amazon and the Plata. The river Beni, whose head waters descend from the mountains near Cochabamba, receives among other tributaries the Mapiro and Coroico, holds first a N. W. and afterward a N. E. course, and joins the Mamoré, which takes its rise in the centre of the country, and flows in a generally N. course to lat. 10° 20' S., where with the Beni it forms the Madeira. Among its tributaries are the Rio Grande, which descends from the S. declivity of the lofty mountains near Cochabamba, and after an immense semicircular sweep falls into the Mamoré near Trinidad; and the Iténez or Guaporé, which, leaving Brazil about lat. 18° 20' S., forms part of the boundary between that empire and the republic until it unites with the Mamoré about lat. 11° 50' S. The Pilcomayo, formed by the united waters of the Cachimayo, Pilaya, and others, flows first E. and then S. E. to the Paraguay. The Bermejo rises in the province of Tarija, leaves the republic parallel with the Pilcomayo, and also joins the Paraguay. The Paraguay enters at the S. E., and, after forming for a distance of about 60 m. the S. E. boundary, leaves the republic in lat. 20° 25' S. All the large Bolivian rivers send their waters to the Atlantic, while the Pacific receives only the Loa, separating the republic from Peru,

and a few mountain streams which force their way through the desert of Atacama.—Trachytic conglomerates in various stages of decomposition are the dominant element in the formation of the maritime Cordillera, and also in that of the more elevated portion of the great plateau of Oruro, as the valley of the Desaguadero is frequently called; the trachyte of the latter region exhibiting, however, great quantities of quartz crystals and saline efflorescence, and being hence unfavorable to vegetation. Although it has been supposed that some of the conical summits of the Cordillera Occidental are extinct volcanoes, no volcanic production is anywhere exhibited in the table land, nor is this region ever visited by earthquakes. In the E. Cordillera granite appears to prevail from the Nevado de Illimani N. W.; its general direction is N. W. and S. E., but it is confined to the more elevated peaks. In its vicinity the trachytic formations invariably become micaceous. Overlooking Cobija is a mass of basaltic porphyry; and E. of the Cordillera Real a few spots of kindred origin mark the eastern limit of plutonic rocks in the lowlands. The Chiquito mountains are formed of gneiss with overlying foliated Silurian strata, the depressions in which formations are filled with sedimentary deposits, containing the fossil remains of colossal mammalia. Overlying this stratum is another of more recent formation, holding shells of existing species.—The mineral wealth of Bolivia consists chiefly in its almost inexhaustible silver mines, principal among which are those of the Cerro de Potosí, in whose conical summit there are over 5,000 openings. It is computed that the mines of this mountain yielded from 1545 to 1789 silver amounting in value to \$1,000,000,000; or with the government fifths or royal dues, and the amount smuggled, a total of \$2,000,000,000 in 245 years. This celebrated mountain still continues to give an annual yield of \$2,250,000. The name Potosí signifies an "eruption of silver." The Indians have at all times been the almost exclusive workers in the mines. Rich silver mines have been discovered in the Sierra del Limon Verde near Calamar, which are said to be greater than any hitherto found in Bolivia, and to yield ore equal to that of Potosí. Silver is also found in many other parts of the republic. Gold occurs in numerous parts of the mountain system. A huge mass of native gold detached by lightning from the base of Illimani was purchased at an enormous price, and sent to the museum of natural history in Madrid. In the sands of all the rivers descending from the Cordillera Real to the Beni or its affluents gold is found in abundance. The tin mines of Oruro are among the richest in the world; and copper is said to be as abundant in the mountains adjacent to Corocoro as was silver in the Potosí. Lead, salt, sulphur, nitre, and other volcanic products are found in large quantities; but these, in common with the

other sources of wealth in Bolivia, are of comparatively little value to the country, owing to the difficulty of transportation. There are innumerable thermal springs in the republic; those of Caiza in the district of Porco, and Urimiri and Machacamarcá near Lake Aullagás, are the most generally known.—Not more than half of Bolivia has a tropical climate, although nearly the whole republic is within the tropics. In the valley of the Desaguadero extremes of heat and cold are unknown. The year is divided into two seasons: the wet or summer, from November to April, when rain falls almost every day, and the nights are cold with occasional frost; and the winter, from May to October, when snow and rain are never seen. The summer is preceded and followed by snow storms. This valley is in general salubrious. The cold in the higher mountain regions is extreme; hail and thunder storms are frequent and terrific; and several maladies of a peculiar nature render abode in these parts exceedingly disagreeable. The *surumpé*, a violent inflammation of the eyes caused by the reflection of the sun's rays on the snow, is attended by severe pain, and sometimes delirium, while the *veta* or *mareo* (seasickness), called by the Indians *puna* or *soroche*, attacks travellers with weariness, blood-spitting, vertigo, fainting fits, &c., and sometimes terminates fatally. In the lowlands S. of the Cordillera Real the heat is oppressive in many of the valleys, and intermittent fevers are common. Goitre is prevalent in the Yungas valleys, but is not accompanied by cretinism as in some parts of Europe. Among the vegetable productions are the potato, which grows wild in many parts; quinoa (*Chenopodium quinoa*), sometimes used as a substitute for the potato; the various cereals; and nearly all the fruits of the tropical and temperate zones. Cotton grows wild, and is of two kinds, yellow and white, both of a fine, long staple; the sugar cane is raised to a considerable extent; the coffee of the Yungas valley is of excellent quality; cacao is abundant on the Beni, and considered to be superior to that of Guayaquil; and the same province and Santa Cruz produce tobacco reputed equal to that of Havana. But perhaps the most important product of Bolivia is the coca, the annual sales of which in the market of La Paz amount to \$4,000,000. It grows extensively along the E. slope of the Andes, between 5,000 and 6,000 ft. above the sea. It is used by the Indians as betel is by the Asiatics and kava by the South sea islanders; and a refreshing tea is also made from it. The country produces in abundance copaiba, sarsaparilla, jalap, valerian, ipecacuanha, and other medicinal drugs; the *canela de clavo*, a species of cinnamon; and many varieties of gums, caoutchouc being abundant and of excellent quality. The fertile strips toward the coast, besides many of the inter-tropical products already mentioned, yield yuca, maize, and algarrobas; and the *arundo donax* is cultivated.

There are vast indigo fields; cochineal is produced; and flax, once prohibited by Spain, is now largely raised. Dyewoods are numerous; and the dense forests afford timber of great beauty, such as ebony, rosewood, mahogany, cedar, Brazil, and a variety of woods not commonly known. The slopes of the Andes are to an immense elevation covered with magnificent trees; here, and in the valleys and the ravines of the mountains, abound cinchona trees, and especially the valuable *C. Calisaya*, from lat. 19° S., following the almost semicircular curve of the Andes, and at an elevation varying from 2,500 to 9,000 ft. above the ocean. Their usual companions, the ferns, *melastomaceæ*, arborescent passion flowers, and allied genera of cinchonaceous plants, are likewise found in rich profusion. The various species of cacti, acacias, and palms are found in their respective zones; as also the *maté*, or Paraguay tea, and a kind of mulberry, from the fibres of which the Indians prepare a beautiful yarn for shirts. A plant called *sapaonane* is used by the Indians to cure headache, and another called *zapatilla* as a laxative; and the leaf of the *matico* is applied to fresh wounds to draw out any foreign substance which might impede the cure. The cereals are sown on the table land, but do not ripen, and are cut green for forage. There are no trees here; the lower districts are clothed with a beautiful green-turf, and the valleys with a coarse grass very good for pasture. The banks of Lake Titicaca are characterized by a luxuriant growth of rushes, used by the Indians to make huts, mats, boats, and for a multiplicity of uses.—The llama, vicuña, alpaca, and guanaco roam in great numbers in the elevated regions; horses, asses, and mules are plenty; and numerous herds of horned cattle find pasture on the banks of the rivers in the plains. The forests are infested with pumas or cougars, jaguars, ocelots, wild cats, and bears. There are several species of monkeys. Peccaries are destructive to the crops; the chinchilla is hunted for its fur; and the burrowings of the bizcacha (*lagostomus trichodactylus*) render travel dangerous on the plains. The flesh of the tapir, carpincho (river hog), sloth, glut-ton, armadillo, and of two species of wild boar is used for food by the natives. There are the condor, gallinazo, and several species of hawks, also a species of ostrich; and the multitude of birds in and about forest, lake, and river is incredible. Of reptiles there are the anaconda and the rattlesnake; and the rivers are infested by caymans. Lake Titicaca abounds in fish of peculiar forms; and in the rivers flowing to the Amazon is the bufeo, a variety of dolphin peculiar to these and the Brazilian waters. The vampire is troublesome in the plains, sucking cattle till death ensues; and there is a hornet called the *alcalde*, of enormous dimensions.—Determined measures have of late been taken to construct roads. Several lines of railway have been planned and

sanctioned by the government: one from Cobija to Potosí, and another to form a branch of the Peruvian railway from Arequipa to Puno. A line to connect La Paz with Achacache on Lake Titicaca was in progress in 1871, and to be opened in 1872. Work commenced in November, 1872, on a railway to connect Mejillones and the celebrated silver mines of Caracoles. The aggregate length of the affluents of the Madeira, with their tributaries, is 5,500 m., perhaps 3,000 m. of which navigated by steamers would afford an easy outlet for the productions of the country. Some steps have been taken in this direction, and the government, to facilitate their execution, has decreed that the rivers of the republic shall henceforth be open for free navigation by vessels of all nations; and in 1868 a New York engineer, Col. George E. Church, contracted for the establishment of a "National Bolivian Navigation Company" on the Madeira, the rapids of which will be avoided by a railway.—A coarse cotton cloth, *tocuyo*, is made in Cochabamba, Santa Cruz, La Paz, and other places, over 600 looms being constantly occupied in the first named city. Santa Cruz produces excellent cordage from vegetable fibres, leather, furs, glass, and other commodities. Fabrics of a fine quality are made with the hair of the llama, alpaca, &c., at La Paz; hats (from the wool of the vicuña) at San Francisco de Atacama; vessels of silver wire in the mining districts; and there are besides various common cloths made by the Indian women. All the Indians are acquainted with the manufacture of gunpowder.—The commerce of Bolivia is limited to the importation of cotton goods, hardware, furniture, jewelry, and silks, in exchange for Peruvian bark, guano, copper ore, tin, borax, hides, furs, woolsens, and wool hats. To facilitate the development of trade, the port of Cobija has been declared free. The total imports in 1871 amounted to \$6,000,000, and the total exports to \$5,000,000. In 1859 the export of calisaya bark through the Peruvian ports of Arica and Islay amounted to \$153,970, and from January to November, 1860, to \$223,850. The internal trade reached in 1868 about \$50,000,000. The state mint at Potosí coins annually about 2,250,000 pesos in silver. The national assembly in October, 1872, adopted a law permitting the exportation of silver in bars from June 1, 1873, subject, however, to an export duty of 50c. per mark, and 20c. per oz. for gold. An export duty of 4 per cent. is still paid on good money.—By the provisions of the constitution of Bolivia, drawn up by Simon Bolivar in 1826, and considerably modified in 1828, 1831, and 1863, the whole executive power is vested in a president elected for a term of four years. The legislative authority rests with a congress of two chambers, the senate and the house of representatives, both elected by universal suffrage. The president appoints a vice president to assist him in his functions, and also a ministry divided into the departments of the interior and

justice, finance, war, and education and public worship. The ministers are liable to impeachment before congress. The seat of the executive government, formerly at La Paz, was transferred to Oruro in 1869. The standing army consists of 31 generals, 359 superior and 654 subaltern officers, 3,034 men, and 522 horses. The annual cost of the army is about \$2,000,000. The revenue in 1867 amounted to \$4,529,345, and the expenditures to \$5,957,275; deficit, \$1,427,930. The revenue is derived partly from a land tax levied upon the Indian population, and partly from the import and export duties, and the proceeds of mines and other state property. Peru pays annually to the Bolivian government \$506,250 for duties collected at the port of Arica on goods *in transitu* for Bolivia. The internal debt of the republic amounted on July 31, 1868, to \$2,181,215, and it was estimated that the interest then past due amounted to a like sum. The country has no foreign public debt, and no paper currency, although the notes of the bank of La Paz have been declared legal tenders.—There are in Bolivia three universities and 348 schools (primary, intermediate, and superior), 294 of which are for males and 54 for females. The annual expenditure for public instruction amounts to about 260,000 pesos. A school of architecture is to be established in La Paz. The religion of the country is Roman Catholic; and though no hindrance is offered to the exercises of other denominations, free and unrestricted toleration cannot be said to exist in Bolivia.—Bolivia was formerly called the presidency of Charcas, and afterward Upper Peru, and formed from 1767 a part of the viceroyalty of Buenos Ayres. It was erected into an independent state in August, 1825, and called Bolivia, in honor of Simon Bolivar. A constitutional assembly decreed, Aug. 11, a republican form of government, appointed Gen. Sucre president, and requested Bolivar to prepare a constitution. Sucre's administration continued till 1828, when he was forced to quit Bolivia by Gen. Gamarra, and was shortly afterward assassinated. His successor, Gen. Blanco, fell a victim to a revolution, headed by Balibian, two months after his inauguration. Mariscal Santa Cruz, then in Chili as minister plenipotentiary from Peru, was elected to the presidency in 1829, and remained in power till February, 1839. He was at the same time president of Peru, with the double character of protector of the Bolivio-Peruvian confederation. Velasco, aided by Balibian, raised a revolution, and having secured the overthrow of Santa Cruz usurped the executive functions, but was himself overthrown by Balibian. The country again pronounced in favor of Santa Cruz, which produced an invasion by Gen. Gamarra, for the purpose of reestablishing Peruvian influence. Balibian accompanied him for a while, but afterward took sides with the Bolivians, and defeated the Peruvian army at

Ingavi, where Gamarra was killed. President Balibian after five years was driven out by another revolution, and succeeded in power for a short time by Velasco, and subsequently by Gen. Belzú (1849). In 1855 Gen. Córdoba was elected president, but was forced to yield to Dr. Linares, who, after nine revolutionary attempts, succeeded in 1858, and exercised power more as a dictator than as president till 1860, in which year he was cast into prison by three of his own officers, one of whom, Acha, had already failed in an endeavor to stir up a revolution against Belzú. Congress, which had been silent for four years, named Acha provisional president in 1861. In December, 1864, Gen. Melgarejo rose against the government of Acha, who was defeated near Potosí in February, 1865. Melgarejo was recognized as president by almost the entire country; but during his absence Gen. Belzú arrived at the capital of the republic, and caused himself to be proclaimed president. Melgarejo soon returned, and took the city by storm. Belzú was killed by one of his own soldiers. An unsuccessful rising against the Melgarejo government took place May 25, led by one Castro Urquedas, whose forces were finally defeated at Viacha, near La Paz, in January, 1866. Bolivia joined in the same year the alliance between Peru, Ecuador, and Chili against Spain, which had just declared war against the last named republic; and one result of that step was a treaty between Chili and Bolivia settling the 24th parallel of S. latitude as the boundary line between the two republics. In 1867 Melgarejo ordered an election for president to take place, and declared that he would not himself be a candidate. In March 10,000 square leagues of fertile territory, watered by the Purus, Jurua, and Jutay, were ceded to Brazil. A revolution broke out in December for the restoration of Acha, who had been until then kept a close prisoner by Melgarejo, and who issued a proclamation enjoining the people to assist him in reestablishing the constitution of 1861, and promising to hold elections for a president irrespective of party or persons. The rebellion was terminated early in 1868, the insurgent leaders emigrating to the Argentine Republic. Melgarejo caused his cousin, one of the bravest officers in the army, to be shot for having attempted to raise a counter-revolution. In September Melgarejo issued a decree extending the rights of citizenship to all Americans. In spite of the continued dissatisfaction with his government, Melgarejo, with the unanimous consent of congress, proclaimed himself again dictator in February, 1869. In May he issued a decree restoring the constitution; but he nevertheless continued to exercise supreme control. The Bolivian government recognized the belligerent rights of Cuba in June of the same year. A new revolutionary movement was set on foot toward the close of October by A. Morales, who but a few years previous had attempted the overthrow

of President Belzú. This movement was speedily crushed, and was renewed with a like result in July, 1870. The following year witnessed a third attempt, which terminated in the complete overthrow of Melgarejo, who escaped to Peru, and was succeeded by Morales, elected for one year. Melgarejo was killed in Lima by his son-in-law, Nov. 23, 1871; and Morales was killed by his own nephew, Nov. 27, 1872.

BOLKHOV, a town of Russia, on the Nuga, in the government and 85 m. N. of the city of Orel; pop. in 1867, 18,491. There are upward of 20 churches, a monastery, and a nunnery. The houses are mostly built of wood. It has factories of gloves, hats, hosiery, leather, tallow, oil, ropes, &c.; and its trade is considerable.

BOLLAN, William, an English lawyer, died in 1776. He went to Boston, Mass., about 1740, married the daughter of Gov. Shirley, and in 1745 was sent to England to solicit the payment of more than \$800,000 advanced by the colony of Massachusetts for the expedition against Cape Breton. After three years he succeeded in obtaining this. In 1769, being in England, he procured copies of several letters calumniating the colonists which had been written by the governors Bernard and Gage, and sent them to Boston, for which he was denounced in parliament. In 1775 he recommended England to adopt conciliatory measures toward the colonies, and John Hancock declared that there was no man to whom the colonies were more indebted. He wrote several works relating to American affairs, among which are "Ancient Rights to the American Fishery Examined and Stated" (London, 1764), and "Freedom of Speech and Writing upon Public Affairs Considered."

BOLLAND, or **Bollandus**, John, a learned Jesuit, born in Limburg or in Brabant in 1596, died Sept. 12, 1665. In 1607 Heribert Rosweyde, a Jesuit of Antwerp, formed the design of collecting memoirs of the lives of all the saints; and this design being finally approved by the ecclesiastical authorities, Bolland was appointed to carry it into effect. At his request Godfrey Henschen was appointed in 1635 as his coadjutor. The plan pursued was chronological, taking up the saints in the order of the calendar, and the work was entitled *Acta Sanctorum*. The first two volumes, treating of the January saints, were published in 1643. The February saints, in three volumes, were completed in 1658. Bolland did not live to finish the March saints, although he prosecuted the work until his death. From Bolland the writers of the *Acta Sanctorum*, who have been appointed from time to time, have been designated as Bollandists. Five years before the death of Bolland the order appointed another colleague, Daniel Papebroek, and the work went on until the March and April saints were completed, and 16 days of May, when Henschen died in 1681. Other successive appointments followed, until, with

two interruptions (the first in 1773, when the order of Jesuits was abolished, and the second in the French revolution), the work reached 53 volumes. It was then for a time suspended, but resumed in 1837, under the patronage of the Belgian government, which appropriated annually 6,000 francs for the continuation of the work. Among the principal Bollandists, besides those already named, were Baert, Jan-ning, Bosch, Suyskens, Hubens, Berthod, and Ghesquière. The 60th volume was published in 1867, in which year the Belgian government withdrew its annual appropriation.

BOLLINGER, a S. E. county of Missouri, drained by affluents of Little river; area, 500 sq. m.; pop. in 1870, 8,162, of whom 46 were colored. The St. Louis and Iron Mountain railroad passes through it. The surface is generally level and the soil fertile. The productions in 1870 were 51,286 bushels of wheat, 395,953 of Indian corn, 135,986 of oats, and 32,210 lbs. of tobacco. There were 2,579 horses, 2,173 milch cows, 3,306 other cattle, 9,808 sheep, and 18,938 swine. Capital, Dallas.

BOLLULOS DEL COUADO, a town of Spain, in the province and 20 m. N. E. of the city of Huelva; pop. about 5,000. The streets are narrow, but there is one public square. The town contains several churches, schools, and convents, a town hall, a prison, and a hospital. The principal products are wine, oil, and brandy.

BOLLMANN, Eric, a German physician and politician, born at Hoya, Hanover, in 1769, died in London in 1821. He practised medicine in Carlsruhe and in Paris, having settled in the latter city soon after the outbreak of the great revolution. He accompanied Count Narbonne in his flight to England in 1792. About this time Lafayette was seized by the Austrians after he had crossed the frontier to avoid arrest by the revolutionary agents, and had been imprisoned at Olmütz. Great pains were taken by the Austrians to keep the place of his detention secret, and for a long time his family and friends could not learn where he was. Lally-Tollendal, who was then a refugee in London, became acquainted with Dr. Bollmann, and being greatly impressed with his courage and address engaged him to search for Lafayette. Bollmann for this purpose established himself as a physician in Vienna, and soon learned that Lafayette was at Olmütz. He now formed a plan to rescue him, in conjunction with Francis Kinlock Huger, a young South Carolinian then travelling in Austria, whose father was a personal friend of Lafayette. Dr. Bollmann made the acquaintance of the surgeon of the prison, and through him contrived to enter into correspondence with Lafayette, who at that time was allowed occasionally to take an airing in a carriage accompanied by two soldiers. On one of these occasions Bollmann and Huger waylaid the carriage, drove away the guards, rescued the prisoner, and mounted him on a horse, directing him to ride to Hoff, where they had stationed a car-

riage in readiness to receive him. Lafayette misunderstood the instruction given to him, and riding in the wrong direction was recaptured and sent back to prison. Bollmann escaped into Prussia, but was soon arrested and delivered up to the Austrians, by whom he was confined for nearly a year, but at length released on condition of quitting the country. He went to the United States, where he was well received, but in 1806 became implicated in Aaron Burr's conspiracy. In 1814 he returned to Europe, and after a second visit to this country settled in London. He wrote several works on banking and on political economy.

BOLOGNA. I. A province of Italy, bordering on Ferrara, Ravenna, Florence, and Modena; area, 1,391 sq. m.; pop. in 1872, 439,166. Its S. boundary is formed by the range of the Apennines, from which descend many streams flowing across the province. Of these the principal is the river Reno, which enters the Po di Primaro near Ferrara. The river lands of the northeast are marshy and subject to floods. The plain of Bologna, in the middle of the province, is very productive, and the valleys and lower slopes of the Apennines are well cultivated. It produces grain, oil, wine, figs, hemp, flax, almonds, and chestnuts, and is celebrated for its silk. The chief minerals are marble, gypsum, chalk, and a sulphate of baryta called Bologna stone, which becomes strongly phosphorescent on being heated with charcoal. The peasants are seldom land owners, but hold their farms from father to son, for a yearly rent of one half the product and taxes. The province is divided into the districts of Bologna, Imola, and Vergato. II. A city (anc. *Bononia*), capital of the province, beautifully situated at the foot of the Apennines, between the rivers Savena and Reno, 185 m. N. by W. of Rome; pop. in 1872, 115,957. It is surrounded by walls about 6 m. in circuit, is 2 m. long and 1½ m. broad, has 12 gates, and is divided into four quarters. The covered porticos or arcades, which afford protection in warm and rainy weather, present an animated appearance, especially in the modern part of the city; while many of the larger thoroughfares look comparatively deserted. The Montagnuola is the only public promenade within the walls. The finest square is the market place, or piazza Vittorio Emanuele (formerly piazza Maggiore or del Gigante), with a famous fountain. The portico de' Banchi on one side of this square, and continued under the name of Paraglione, forms a continuous arcade 300 ft. long, with some of the finest stores. In this neighborhood are many palaces, prominent among which are the *palazzo pubblico* or *del governo*, and the *palazzo del podestà*, containing the archives, and having a lofty tower rising upon arcades. Many of the private palaces are hardly less remarkable for antiquity and works of art. Near the exchange is a large space, from which four streets branch off to the principal gates, and containing two famous leaning

towers (torre degli Asinelli and torre Garisenda or Mozzh), respectively about 300 and 150 ft. high, and built in the 12th century. Remains of similar towers exist in various parts of the city. Conspicuous among the houses are the casa Rossini, in the via Maggiore, built in 1825 by that composer, who long resided here; the casa Lambertini, in the via della Campana, the birthplace of Pope Benedict XIV.; that of the

Leaning Towers, Bologna.

electrician Galvani, in the borgo delle Casse; and the residences once occupied by the painters Guercino and Guido. There are about 130 churches, including the ancient cathedral, restored in the 17th and 18th centuries, with famous relics and pictures; the elegant church of San Bartolommeo di Ravennana, of the 17th century, on the site of one built by St. Petronius; San Bartolommeo di Reno, with paintings by the Carracci; and San Domenico, with the tombs of St. Dominic, King Enzo, Taddeo Pepoli, and Guido. The church of San Francesco, behind the post office, which was one of the most extensive of all, was converted in 1798 into the custom house, but has lately been restored. Its bell tower is one of the finest in Bologna. The monument of Pope Alexander V., who was buried in this church, has been removed to the Campo Santo. The basilica of San Petronio, founded in 1390, is the largest church of Bologna, and, though unfinished, one of the most imposing, especially in the interior; over the great door stood the colossal bronze statue of Pope Julius II., by Michel Angelo, which was destroyed in 1511. The emperor Charles V. was crowned here by Clement VII. (1530), and the meridian line by Cassini was traced on its floor in 1653. Especially noticeable for its great antiquity and extent among the other churches is that of San

Stefano, formed by the union of seven chapels, and presenting a labyrinth-like and strikingly mediæval appearance.—The university, which is said to have been founded by Theodosius II. in 425, and is celebrated as the oldest in Italy and as the first to confer academical degrees, was the principal seat of learning in the middle ages, and acquired special renown in jurisprudence in the 12th century by the influence of Irnerius. Many thousand students gathered there in that period from all parts of Europe. Medicine, the arts, and theology were taught subsequently, in addition to civil and canon law. In the 14th century dissection was practised there for the first time, and at a later period its renown was increased by the discovery of galvanism. Many learned women acquired distinction here as teachers, and more recently in the chair of anatomy. The university is still attended by about 600 students annually, and retains a high reputation, chiefly in medicine. It was richly endowed by many of the German emperors, especially by Frederick I., by the princes of Italy, and by several popes; and the Bolognese were so proud of it that they had the academical motto, *Bononia docet*, engraved upon their coins. The library, in which Mezzofanti was employed for some time, contains about 200,000 volumes and 6,000 MSS. The institute of science was founded in 1690 by Count Marsigli, the friend of Newton, who also secured the establishment of an observatory, an anatomical museum, and a botanical garden, and presented the city with collections of natural history and scientific instruments. These various institutions are in the imposing palace of the university, in the strada San Donato, formerly the palazzo Cellesi. In the same street, in a former convent, is the academy of fine arts, or *accademia Clementina*, founded by Pope Clement XIII., with the celebrated *pinacoteca* or gallery of paintings by Bolognese masters. The *oploteca* contains a collection of arms and a library, and on the ground floor are various schools of design. Among the great educational institutions and public buildings is the *archiginnasio*, with a public library, the gift of Magnani, a native of Bologna. The Venturoli college, founded in 1825 by the architect of that name, is in the locality formerly used as the Hungarian college, and is an architectural school for students below the age of 20. Among the various societies is one for agriculture, and a Socratic society for humanitarian purposes. Bologna boasts of being the most musical city of Italy, and in 1872 conferred the freedom of the city upon Richard Wagner. The *accademia filarmonica* has a wide reputation, as well as the *liceo filarmonico* in the convent of San Giacomo, which is a musical school with a library of 17,000 volumes of printed music and the collections of Martini. The Zaprioni theatre is the largest, and the Corso theatre, built in 1805, is the most popular. The Contavalli theatre was built in 1814, partly on the site of a former con-

vent. The public cemetery, or *campo santo*, about 1 m. from the gate of San Isaia, on the site of the ancient Carthusian monastery Certosa, built in 1335 and suppressed in 1797, was consecrated in 1801 under the direction of Napoleon I., and is one of the finest and most extensive in Italy. It is approached by a covered portico of arches, and contains many large halls. The church of the monastery has been preserved, with its chapels and fine pictures. Among other interesting monuments, the cemetery contains a pantheon of university professors who are buried here, and whose busts are placed in the hall. A small separate space is reserved for the burial of Protestants. In the environs of the city there are many famous churches, including the nunnery and church of Madonna di San Luca, on the summit of the monte della Guardia, with a magnificent view, and a miraculous relic of the Virgin, attributed to St. Luke. This is a great resort of pilgrims, whose annual visit is celebrated by a public festival. It is approached by a covered portico of columns with 654 arches. Conspicuous among relics of antiquity are the ruins of the so-called baths of Marcus and of a temple of Isis.—Bologna is famous for poodle dogs and sausages (*mortadella*), but the pure breed of the former has become very scarce. There is an active trade in macaroni, salami, *cervellato* (a peculiar plum pudding, only made in winter), liqueurs, prepared fruits, artificial flowers, aromatic soaps, and particularly in silk. The wines of the vicinity are not bad, and among fruits the grape is the best. Bologna is regarded as the hottest city in Italy in summer, and as rather cold in winter, but the climate is healthy. The principal hotel occupies an ancient Roman palace, and there are many cafés. The local dialect, once admired by Dante as the purest of Italy, has become one of the most puzzling and least intelligible of all Italian jargons. The epithet *grassa* (fat) has been applied to Bologna on account of the epicurean habits of the inhabitants and the fertility of the environs. The Bolognese have been described by Tassoni as an uncontrollable people, in allusion to their sturdy spirit of independence. They rank at present among the most cultivated and public-spirited citizens of Italy.—Bologna was founded by the Etruscans under the name of Felsina. It was long held by the Boian Gauls, and in 189 B. C. became a Roman colony with Latin rights, under the name of Bononia. It was subsequently a place of much importance, figuring chiefly in the civil wars which followed the death of Cæsar, and retained its prosperity after the fall of the Roman empire. Charlemagne made it a free city. In the 12th century it attained the zenith of its greatness as a republic, which, however, fell in the subsequent century, owing to intestine strife among the nobles. After having been alternately under papal dominion and under that of the Geremei, Lambertazzi, Pepoli, Bentivoglio, and other local princely

families, who successively contended for supremacy, the city voluntarily became in 1518 a papal province, though retaining many of its ancient privileges till 1796, when the French united it with the Cisalpine republic, afterward incorporating it with the kingdom of Italy. In 1815 it was restored to the Papal States. In 1821 it became the focus of republican agitation and the seat of a provisional government, and the papal governor was obliged to leave the city; but the insurrection was put down after the occupation of the city by Austrian troops. The mismanagement of custom house officials in 1843 and other vexations became a new source of commotion, in consequence of which many Bolognese were arrested and others fled. On Aug. 14, 1848, an attempted Austrian occupation was gallantly prevented by the rising of the populace, and the invaders were expelled, leaving their dead and prisoners behind. After the conclusion of the treaty of peace with Sardinia, however, the Austrians returned with the concurrence of Pius IX., and after a resistance of eight days and a repeated bombardment, Bologna had to surrender, May 16, 1849, and an Austrian garrison occupied the city till 1859. Bologna then seceded from the Papal States, and in 1860 became with the rest of the Romagna part of Victor Emanuel's dominions.

BOLOGNA, Giovanni da, an Italian sculptor and architect, born at Douay in Flanders about 1524, died in Florence in 1608. He studied art when a youth at Rome and Florence, which last city he made his home. He surpassed all sculptors of his time except Michel Angelo, and few artists were charged with the execution of so many and such important works. His surname of Bologna seems to have been derived from the celebrated fountain in that city, designed by himself, of which the crowning colossal figure of Neptune is one of the wonders of art. At Florence, however, are to be found his finest works, such as the celebrated "Rape of the Sabine Women," a group in marble, and the equally celebrated bronze of Mercury.

BOLONCHEN, a village of Yucatan, 60 m. E. N. E. of Campeachy. In the plaza of the village are nine ancient wells, cut through a stratum of rock, and communicating with a common reservoir. In the vicinity is a large cave which contains seven pools of water, of which one is 450 ft. beneath the surface of the ground. These supply the village when the wells fail in the summer months.

BOLOR TAGH, or **Palolo Tagh**, properly the W. portion of the Karakorum range of mountains in central Asia, lying between the sources of the Gilgit and the Nabra, affluents of the Indus, and separating Cashmere from Chinese Turkistan. This range on the west merges in the Hindoo Koosh. The name is, however, generally applied to the Belur or Belut Tagh, a range which, running N. and S., connects the chains of Thian-shan and Kuen-lun, and forms the W. boundary of Chinese Turkistan.

BOLSENA (anc. *Volsinii*), a town of Italy, on a lake of the same name, in the province and 56 m. N. N. W. of Rome; pop. about 2,100. Volsinii, originally built on a height in the neighborhood, was one of the most powerful Etruscan cities. It was frequently at war with the Romans, who finally took it in 280 B. C., razed it, and built a new town on the present site of Bolsena, retaining the name. Of the Etruscan town there is no vestige, and even its site is uncertain; but the remains of the Roman one are numerous, including portions of temples and of an amphitheatre, and numerous sepulchres and tumuli, in which many Etruscan vases, statues, &c., have been found. The

Bolsena.

lake of Bolsena, which is supposed to fill an ancient crater, exhales a deadly malaria during the summer season. It is about 9 m. long, 7 m. broad, and 285 ft. deep, and is famous for its eels. The shores are formed by finely wooded hills, presenting much beautiful scenery; it has two small islands, called Martana and Bisentina, and it discharges by the Marta river, flowing into the Mediterranean.

BOLSWERT, or **Bolsward**, **Boetius Adam**, a Dutch engraver, born at Bolsward in Friesland in 1580, died in 1634. He executed many valuable engravings after designs of Bloemaert and Rubens.—His younger brother, **SCHELTIUS**, rose to higher fame in the same art, especially distinguishing himself by his prints after some of the best works of Rubens and Vandyke. Both brothers practised their art at Antwerp.

BOLTON, or **Bolton-le-Moors**, a manufacturing town and borough of Lancashire, England, 11 m. N. W. of Manchester; pop. in 1871, 82,854. The Croal, a tributary of the Irwell, divides the place into Great and Little Bolton. The manufacture of woollens was introduced here by the Flemings in 1337, but the inventions of Arkwright and Crompton, both natives of the place, laid the foundation of its present prosperity.

It is now one of the principal seats of the cotton manufacture in England. The bleach and dye works here are among the largest in the kingdom, and it has also print works, extensive foundries, steam engine and machine works, paper, flax, and saw mills. Numerous coal pits are worked in the vicinity. The town is well supplied with water, and is connected by canal and railway with Manchester and Bury, and by railway with Liverpool, Preston, Leigh, and Blackburn. It sends two members to parliament.

BOLZANO, **Bernhard**, a German philosopher and Roman Catholic theologian, born in Prague, Oct. 5, 1781, died there, Dec. 18, 1848. He

was professor of divinity in the high school of Prague from 1805 to 1820, and, supported by the archbishop of Prague, withstood the opposition of the ultramontanes, who regarded him as a follower of Schelling. In 1820 he was suspended, and hampered in his literary activity and social intercourse. His high character, piety, and benevolence secured for him a host of friends, and he lived for many years on the estate of one of them near Prague, and afterward in that city with the assistance of Count Leo von Thun. His

principal works are: *Lehrbuch der Religionswissenschaft* (6 vols., Sulzbach, 1834); *Wissenschaftslehre, oder Versuch einer neuen Darstellung der Logik* (4 vols., 1837); and *Athanasia, oder Gründe für die Unsterblichkeit der Seele* (2d revised ed., 1838).

BOMARSUND, a narrow channel between the island of Aland and Vardö, at the entrance of the gulf of Bothnia. This channel was formerly commanded by the strong Russian fortifications on the S. E. extremity of Aland, which were destroyed by the allied fleets in 1854.

BOMBAY. **I.** A province (formerly presidency) and one of the ten great governmental divisions of British India, bordering on the Arabian sea, and lying between lat. 14° and 29° N., and lon. 66° and 77° E. It comprises a strip of territory about 900 m. in length, extending from the northern limit of Sind to the kingdom of Mysore on the south, along more than two thirds of the W. coast of Hindostan. Its greatest breadth is 250 m. According to the British parliamentary accounts for 1870, the area is 87,000 sq. m., and the population in 1871 was 13,983,998. The province contains 22 districts, apportioned among three commissionerships, Sind in the north, and the northern

and southern divisions of Bombay proper, in which are comprehended Ahmedabad, Kaira, Surat, Broach, Bombay island, Darwar, Candeish, Tanna or North Concan, Rutnagherry or South Concan, Poonah, Ahmednuggur, and Canara. The large native feudatory states of Cutch and Guzerat, the chiefs of which are subject merely to British supervision, intervene between Sind and the northern and southern divisions. The coast line is about 1,050 m. in length. Considered with reference to its physical characteristics, the province is divisible into four regions: 1, the Sind territory, in the north, comprising the low and level basin of the Indus, where strips of exceedingly fertile country alternate with deserts produced by lack of irrigation; 2, the two Concans, which form the rugged and hilly maritime belt, about 330 m. long and from 25 to 50 m. wide, lying between the Western Ghats and the Arabian sea; 3, the eastward slope of the Western Ghats; and 4, the flat, alluvial tracts W. of the gulf of Cambay, in the Nerbudda districts. There are great meteorological differences between these several regions. The climate of Sind is exceedingly sultry and dry, with a very light

rainfall, and an average maximum temperature at Hyderabad, the capital, of 98.5° F. in the shade. In the Concans, on the other hand, while the heat is as great, the annual fall of rain is much larger. This is due to the action of the Western Ghats in condensing the vapors of the S. W. monsoon as it blows in from the sea; but the same cause leaves the eastward slope of the range comparatively rainless. At Bombay island the average annual temperature is about 80° F., with a maximum of about 100° in the shade; and the rainfall averages 80 inches per annum, sometimes rising nearly to 100 inches. The Western Ghats are the most important mountains in the province; within its boundaries the altitude of the range varies from 1,000 to 4,700 ft. The Indus, Nerbudda, and Taptee are the principal rivers. The vegetable productions comprise cotton and rice in the coast districts, sugar and indigo in Candeish, and wheat, barley, hemp, and tobacco in Sind. Opium is manufactured in the native states of Malwa and Guzerat, and merchants who wish to send it to the city of Bombay obtain permits from the government at a certain price per chest. Consider-

Bombay, from Malabar Hill.

able quantities of silk are raised, and there are silk manufactories in some of the towns. The land revenue system of Bombay was carefully planned and put in operation about 20 years ago. It provides for a survey and assessment of the whole province, which work is now almost completed. With few exceptions, the occupants of the land hold directly from the government, and pay their rent to government officers. The fields are mapped, and marked out by permanent objects, to remove which is a penal offence; they are then classified for assessment, with reference to the soil, climate, proximity to market, and other external conditions. When the existing rate was fixed, it was equal to one half the yearly value of the land; but in consequence of the general im-

provement of the country the proportion is now not more than one fourth or one eighth of that value, except in the poorer districts. A revision of the assessment may be made at the end of every 30 years. The land revenue yields a larger sum per capita in Bombay than in any other province of India. The administration is vested in a governor appointed by the crown with the advice of the secretary of state for India. He is assisted by three councillors and a legislative council. There are 300 schools in the province, under government supervision, with an attendance of 13,000 scholars, five sixths of whom are instructed in the native languages only, the remainder being taught English. Religious establishments are maintained by the churches of England and

Scotland. In the year ending March 31, 1870, the value of the imports into the province was £22,232,485, and of the exports from it £24,690,819. The length of the railway lines open for traffic there on Dec. 31 of the same year was 1,184 m. The chief towns, in addition to the city of Bombay, are Hydrabad and Kurrachee in Sindh, Surat and Baroda in the region E. of the gulf of Cambay, and Poonah in the highlands E. of the Ghauts, 2,000 ft. above the sea level.—The sepoy mutiny of 1857 did not attain any serious magnitude in Bombay. A few conspiracies were detected in widely separated localities, and immediately suppressed. The native troops remained for the most part faithful to the British. Two ring-leaders in a plot for the massacre of all the European residents of the capital were summarily punished by being blown away from the mouths of cannon. II. A city, capital of the province, picturesquely situated on an island of the same name close to the W. coast of Hindostan, in lat. 18° 56' N., lon. 72° 53' E., separated from the mainland by an arm of the sea; pop. in 1871, 646,636, of whom about 450,000 were Hindoos, 120,000 Mohammedans, 30,000 Parsees, and 8,000 Europeans. The island, which was the first possession ever acquired by the British in India, is 8 m. long and nearly 3 m. wide, and the city occupies its southern extremity. Toward the close of the 15th century it was conquered by the Mohammedans, who ceded it to the Portuguese in 1530. Shortly before the marriage of Charles II. and Catharine of Bragança, infanta of Portugal (1662), it was conveyed to the English crown as a portion of the dowry of that princess. About seven years later the king transferred it to the East India company, who held it at an annual rental of £10 sterling up to the year 1859, when the home government assumed direct control of all the British East Indian possessions. Bombay is the busiest and in appearance the gayest of the cities of British India. The ancient portion is known as the Fort, and contains numerous handsome buildings. The houses within the walls are built of wood, surrounded with verandas, and covered with sloping roofs of tiles. The poorer classes occupy dwellings of clay thatched with palmyra leaves. There are many large store-houses and commercial establishments, and in the European quarter are numbers of fine residences. Of the public buildings the more prominent are the Anglican cathedral, the various churches, temples, and synagogues, the government house, the town hall, the custom house, the Grant college of medicine, and the hospital founded by the Parsee merchant Sir Jamsetjee Jejeebhoy, and bearing his name. The city is now connected with the neighboring island of Salsette by means of a recently constructed causeway and arched stone bridge. By far the most interesting structures in the vicinity of Bombay are the celebrated cave temples of the Buddhists, excavated from the

solid rock and adorned with colossal statues, on the island of Elephanta, which lies at a distance of from 6 to 8 m.—The harbor of Bombay, as the name of the city indicates, is safe and commodious, being one of the best in all India. It is enclosed by Colabba, or Old Woman's island, Bombay island, and the island of Salsette, on the west and north, and by the islands of Elephanta and Caranja, together with the mainland, on the east. It is between 12 and 14 m. long, between 4 and 6 m. wide, and has a depth of from 7 to 14 fathoms. A lighthouse 150 ft. high stands on the southern end of Colabba island. The rise and fall of the tide are sufficient to permit the construction of wet docks capacious enough for building large ships; and in those belonging to the East India company merchant vessels of the largest class, and even frigates and line-of-battle ships, have been built by the Parsees. As the material used for ship building at Bombay is exclusively teak, the vessels constructed there are noted for their durability. The city is both a naval and a military station, but the fortifications, although extensive, are not adequate for defensive purposes against a well equipped foe. Preëminent among the natives for their intellectual capacity, their industry, their business ability, and their great wealth, are the Parsees, the descendants of the ancient fire-worshippers. Socially, commercially, and politically, they constitute, after the Europeans, the most influential class in Bombay. Their walled cemetery, carefully guarded, stands on the summit of Malabar hill, the most fashionable suburb of the city. It contains five round towers, each about 60 ft. in diameter and 50 ft. in height, and surmounted by a large grate. The bodies of the newly dead are placed upon these towers, and when the vultures have removed the flesh from the skeleton, the bones fall through the grate into the enclosure beneath.—The external trade of Bombay is very extensive, and is carried on principally with Great Britain, France, China, Mauritius, and the ports of the Arabian sea and Persian gulf. Cotton is by far the most important article of export. The rise in price and the increased demand growing out of the civil war in America were followed by an era of the wildest speculation in commercial circles at Bombay, from 1862 to 1865, resulting in a financial panic so disastrous that for a time there was said to be not one solvent merchant in the entire city. The exceptional activity of this period, however, contributed in no slight degree to its present prosperity. The exports of cotton to Europe for six years ending with 1872 averaged nearly 1,100,000 bales a year. In 1863-4 opium to the amount of £5,548,158 was exported, principally to China. The other leading exports, in the order of their total values, for the same year, comprise wool, seeds, cashmere shawls, coffee, grain, spices, sugar, tea, silk and silk goods, saltpetre, and tobacco. The first railway in the East Indies

was that between Bombay and Tanna, opened April 6, 1853. Bombay is now the terminus of the Bombay, Baroda, and Central India railway, and of the Great Indian Peninsula railway, as well as of steamship lines from England. There is telegraphic communication with Calcutta, opened in 1854, and with Falmouth, England, opened in 1870, by means of cables, avoiding all land communications, by way of Aden, Malta, and Gibraltar. As the capital of the province, Bombay is the residence of the governor and of an Anglican bishop. The provincial high court is also held there. Prominent among the institutions of the city is the royal Asiatic society, famous for its successful efforts in behalf of oriental learning. Several missionary establishments are maintained by Europeans and Americans.

BOMBELLI, Raffaello, a Bolognese mathematician of the 16th century. He published in 1572 a treatise on algebra, in which he first attempted the solution of the "irreducible case" in cubic equations. He gave the geometrical solution depending upon the trisection of an angle, which latter problem, he observed, could be reduced to a cubic equation. He was also the first to attempt the extraction of the cube root in the result of Cardan's formula.

BOMBERG, Daniel, a Dutch printer, born in Antwerp, died in Venice in 1549. He printed several renowned editions of the Hebrew Bible, the first of which appeared at Venice in 1518. The Babylonish Talmud and many other Hebrew books were issued from his press in a style of execution so expensive as to ruin him.

BONA (Fr. *Bone*; Arabic, *Beled el-Anib*, town of grapes), a fortified seaport town of Algeria, in the province of Constantine, on the W. coast of the gulf of Bona, 270 m. E. of Algiers; pop. in 1866, 17,841, more than half Europeans. It is built in the form of an amphitheatre in an extremely fertile region, at the foot of a hill, and

tions. Outside the walls, which are flanked with four square towers and pierced by four gates, is the citadel, built by Charles V. in 1535. Its capture by the French, March 26, 1832, was one of the most brilliant achievements of the French invasion. Since 1850 it has been used as a prison of state. Though the harbor is not favorably situated, commerce is active, but less so than formerly, part of it having been diverted to Philippeville since the establishment of that port in 1838. The coral fisheries are extensive. Silks, tapestry, and other articles are manufactured, and the town contains a marble quarry, an iron foundry, and other industrial establishments, and has weekly communication by steam with Marseilles. A marsh, between the town and the junction of the Seibous with two of its affluents near the entrance of the former river into the sea, is productive of malaria, and is supposed to have been the ancient harbor of Hippo Regius, the scanty remains of which town are about 1½ m. S. by W. of Bona. (See Hippo.)

BONA, Giovanni, a Roman cardinal, born in Mondovì, Piedmont, Oct. 10, 1609, died in Rome, Oct. 27, 1674. He was a collaborator in the *Acta Sanctorum*, the author of *Res Liturgicæ*, which is an authority on the service of mass, and of *De Principiis Vitæ Christianæ*, of which French translations appeared in 1693 and 1728. An edition of his works appeared at Turin in 1747-'53, in 4 vols.

BONA DEA (the good goddess), a Roman divinity, sister, wife, or daughter of Faunus. Her worship was secret, performed only by women; and men were not allowed to know her name. Her sanctuary was in a cavern in the Aventine hill, but her festival, which occurred May 1, was celebrated in a separate room in the dwelling of the consul who then had the fasces. No man was allowed to be present, all male statues in the house were covered,

and the myrtle was avoided in the decoration of the house with flowers. The wine used at this festival was called milk, and the vessel in which it was kept *mellartum*. After a sacrifice, called *damium*, the wine was drunk and bacchanalian dances were performed. According to Juvenal, licentious abominations marked these festivals. The snake was the symbol of the goddess, indicating that she was regarded as possessing a curative medical power. In her sanctuary various herbs were offered for sale.

BONACCA (formerly called GUANAJA), an island in Honduras bay, Caribbean sea, 30 m. N. of Cape Castilla; lat. 16° 28' N., lon. 85° 55' W. It is the second in size of the group called the

Bona.

has been Europeanized and embellished by the French, who have improved the harbor and in 1858 built new piers. The town is well supplied with churches, schools, and public institu-

Bay Islands, is about 9 m. long and from 1 to 3 m. broad, and rises to a height of 1,200 ft. The island was discovered by Columbus in his fourth and last voyage, July 30, 1502. The aborigines had made considerable advances in civilization, and carried on an active trade by means of large boats with the mainland of Honduras and Yucatan, and, it is said, even with Jamaica. The Spaniards and afterward the buccaneers harassed them so much that they abandoned the island in 1642, and took refuge on the mainland. The buccaneers fortified the island and held it till 1650, when they were expelled by the Spaniards. In 1742 the English seized Bonacca and the neighboring island of Ruatan, which they fortified and held till it was captured by the Spaniards in 1782. When Central America became independent in 1821 Bonacca and the other islands of the group came under the jurisdiction of Honduras. In 1850 a British naval commander declared them under the sovereignty of Great Britain, and in 1852 the group was constituted by royal proclamation the British "Colony of the Bay Islands." This act, being in contravention of the convention between England and the United States known as the "Clayton and Bulwer treaty," led to an animated controversy between the British and American governments, which was at length settled by restoring the islands to Honduras in 1859.

BONALD. I. *Louis Gabriel Ambroise*, viscount de, a French political writer, born at Le Monna, near Millau-en-Rouergue, Oct. 2, 1754, died there, Nov. 23, 1840. When young he served in the *mousquetaires*. In 1791 he emigrated, and joined the royalist army on the Rhine. Returning to France under Napoleon, he became, with Chateaubriand and Fiévée, editor of the *Mercur*, and after the restoration he was a member of the chamber of deputies, always favoring an absolutist and reactionary policy. In 1823 he was made peer by Louis XVIII., and as one of the secretaries of state presided over the censorship of the press. At the revolution of 1830 he resigned his seat as a peer, and retired from public life. His literary labors were devoted exclusively to establishing the theory of power in society, its origin and extent; and he drew his demonstrations from history, philosophy, religion, and the philological meaning of words. He denied the validity of reason, and recognized absolutely that of authority. But above the highest civil authority, that of legitimate kings, he affirmed that of religion, or the church and its hierarchy. His complete works were published in 12 vols., Paris, 1817-'19, the principal being *La législation primitive, Théorie du pouvoir politique et religieux, Recherches philosophiques, and Mélanges littéraires et politiques*. II. *Louis Jacques Maurice*, a French cardinal, son of the preceding, born at Millau, Oct. 30, 1787, died in Lyons, Feb. 25, 1870. He became archdeacon of Chartres in 1817, bishop of Le Puy in 1823, and archbishop of Lyons in 1839, and

bore for a time the title of primate of the Gauls, which Pius IX. afterward forbade him to retain. He was created cardinal in 1841. He became conspicuous as a champion of the rights of the church against the civil power, and as an opponent of the liberty of education, for which Lamennais, Lacordaire, Montalembert, and the rest of the young Catholic party were then contending. His controversies with Dupin and Villemain on these subjects were especially vigorous. He was a legitimist in politics, but gave a ready adhesion to the republic of 1848. Under the empire he held a seat in the senate by virtue of his rank as cardinal. In September, 1852, he was created a commander of the legion of honor.

BONAPARTE, or *Buonaparte*, the name of the family which has given to modern France its imperial dynasty. Its early origin is obscure. The name occurs in Corsica as early as the middle of the 10th century, being that of a *messire* who figured as witness to a public document. It disappears, however, in that island, not to reappear until the 16th century. In the mediæval history of Italy a number of Bonapartes are mentioned, but criticism has as yet failed fully to establish or to disprove the pretended connections between their families. We find Bonapartes at Treviso, Florence, Parma, Padua, Ascoli, Bologna, San Miniato, and Sarzana, many of them noblemen of note and ability. A Trevigian Bonaparte, Giovanni, who held a command in the army of the Lombard league against the emperor Frederick Barbarossa, is designated as *consul et rector*. Those of Florence were originally Ghibellines, but subsequently espoused the popular cause. A Niccolò Bonaparte served as papal envoy to various courts about the middle of the 15th century. Jacopo Bonaparte, of Tuscany, is the reputed author of a history of the sack of Rome by the army of the constable de Bourbon (*Ragguaglio storico di tutto l'occorso, giorno per giorno, nel sacco di Roma del anno 1527*), of which a French translation by the ex-king Louis of Holland was published at Florence in 1830. The modern Corsican Bonapartes seem to be chiefly connected with those of Sarzana. They figure among the patricians of Ajaccio in the 16th and 17th centuries. At the middle of the 18th, three male members of that branch were living, one of whom, Carlo, became the father of the founder of the French imperial dynasty, sketches of all the historical members of which are given in the following notices—first of the father and mother of Napoleon, with their daughters, then of their sons in alphabetical order, each followed by the noteworthy members of his family.

BONAPARTE, or *Buonaparte*. I. *Carlo Maria*, father of Napoleon I., born in Ajaccio, March 29, 1746, died in Montpellier, Feb. 24, 1785. He studied law in Pisa, and early acquired prominence as an advocate and a follower of Paoli in the Corsican war against Genoa. In his 18th year he fell in love with Maria Le-

tizia Ramolino, whose family belonged to the Genoese faction, and were adverse to the marriage, which did not take place till 1767. His wife accompanied him during his campaign, and dissuaded him from following Paoli in his flight to England. He afterward entered into friendly relations with Count Marboëuf, the French governor of the island, and became assessor of the city and province of Ajaccio, deputy of the Corsican nobles to the court of France (1777-'9), and in 1781 one of the 12 members of the council of the Corsican nobility. Through the munificence of the government his son Napoleon was admitted to the military school of Brienne, Louis to the seminary at Autun, and his daughter Elisa to the royal institution of St. Cyr. Afflicted with an ulcer in the stomach, he sought medical advice in Montpellier, and died in that city in the presence of his son Joseph and of his wife's brother, afterward Cardinal Fesch. He was a fine-looking, intelligent, amiable, and courageous gentleman. His portrait is in the Versailles museum, and his marble bust by Elias Robert was executed in 1855. His wife bore him 13 children, of whom five sons, Joseph, Napoleon, Lucien, Louis, and Jérôme, and three daughters, Elisa, Pauline, and Caroline, survived him. **II. Maria Letizia** (called by the French *Madame Letitia*), wife of the preceding, born in Ajaccio, Aug. 24, 1750, died in Rome, Feb. 2, 1836. She was of an austere and classical style of beauty and commanding appearance, and her courageous spirit revealed itself after her marriage, when she went through the ordeal of camp life, in company with her husband, shortly before giving birth to her son Napoleon. She was overtaken with the first pains of labor while at church, and had barely time to reach her home. After the death of her husband she devoted herself to the education of her children; and in 1793, when Corsica fell into the hands of the English, she escaped with her three daughters and Lucien, in the midst of many perils, from Ajaccio to Marseilles, where she lived in penury upon the pittance which the government allowed to Corsican refugees. Her position was greatly improved after Napoleon's promotion to the chief command of the French army in Italy, and on the establishment of the consular government she removed to Paris. Her mode of existence, however, continued to be frugal and unpretentious, even after her son's accession to the throne, when she received the title of *Madame Mère*. Napoleon found fault with her predilection for Lucien, and afterward with her inveterate dislike of Maria Louisa, and always with her repugnance to display. But though she occasionally suffered from his want of filial affection, he insisted upon the utmost reverence being shown to her. Her education and disposition were not suitable for a prominent position in the brilliant society of Paris; and though a patrician by birth, of great natural dignity of manners, and possessed of consider-

able tact and judgment, her culture was deficient and her tastes were simple, and her habitual circle included only Madame Saveria, the faithful teacher of several of her children, and a few other intimate friends. She saved large sums of money, which afterward enabled her to assist her children in distress; and though economical almost to parsimony, she was lavish in dispensing charities, at the head of which she was placed officially. After the downfall of Napoleon, she went with several of her children to Blois, and then to Rome. She visited her son at Elba, and sternly rebuked Caroline's defection, admonishing her rather to trample upon the corpse of her husband Murat than to desert her brother and benefactor. In April, 1815, she returned to Paris; and after the battle of Waterloo she took up her abode in Rome. Denounced in 1820 as a Bonapartist agitator by M. de Blacas, the French ambassador in Rome, she indignantly repelled the accusation, and declared with an unusual vehemence, the effect of which was enhanced by her general impassibility, that if in reality she could dispose of millions, she would not spend them in such attempts, but would devote her means exclusively to effect the release of her son from St. Helena. In 1830 she broke her thigh, and was ever afterward confined to her room. She left to her children a fortune represented by a revenue of 80,000 francs, and about 500,000 francs worth of jewelry. In the museum of Versailles are two portraits of her, painted by Gérard. In her celebrated statue by Canova she is represented in the attitude of Agrippina in the capitol. **III. Marie Anne Elisa Bacciochi**, daughter of the preceding, born in Ajaccio, Jan. 3, 1777, died, according to most accounts, at the villa Vicentina, near Trieste, Aug. 7, 1820. She left St. Cyr after the suppression of that educational establishment at the end of 1792, and married at Marseilles in May, 1797, Felice Pasquale Bacciochi, a poor Corsican officer of noble lineage. In 1798 she removed to Paris, where her house became a resort of Chateaubriand, La Harpe, and other eminent persons, including Fontanes, her special favorite. Napoleon made her in 1805 princess of Piombino and Lucca, and in 1808 grand duchess of Tuscany. She was called the *Semiramis of Lucca* on account of her administrative talents. She put down brigandage and promoted the prosperity of her small dominions. She lived in great state at Florence, Pisa, and other places till 1814, when she retired to Bologna. Early in 1815 she went to Austria, where after Murat's death she was joined by his widow, her sister Caroline, spending her last years under the title of countess of Compignano, near Trieste, in which city she was buried. Her husband, though crowned with her at Lucca, held a subordinate position during her life. They had two sons. (See BACCIOCHI.) **IV. Marie Pauline**, sister of the preceding, born in Ajaccio, Oct. 20, 1780, died in Florence, June 9, 1825. She had no advantages of education, but

was remarkably brilliant and beautiful. In her 14th year Fréron fell in love with her, and she would have married him if Napoleon had not discovered that his first wife was living. Her next suitor, Gen. Duphot, was killed in Rome in 1797; and Junot applied in vain for her hand, which she bestowed in 1801 upon Gen. Leclerc, whom she accompanied to Santo Domingo. She declined to leave him despite the rising of the negroes and the outbreak of the yellow fever; and after her husband had died of that disease (Nov. 2, 1802), she conveyed his remains to France. Their only child died one year after her second marriage in 1803 with Prince Camillo Borghese, who, being the heir of an illustrious princely family of Rome, was selected by Napoleon as a valuable brother-in-law. He almost immediately separated from his wife, whose virtue he suspected, and he only became reconciled to her in her illness toward the end of her life. Napoleon doted upon Pauline, and made her duchess of Guastalla; but he rebuked her excessive jealousy of Josephine, and resented her rudeness to Maria Louisa by banishing her from his court. She nevertheless led a gay life in the vicinity of Paris and subsequently at Nice, gathering round her many fashionable people of easy virtue. The news of her brother's downfall in 1814 reached her in Italy. Forgetting all previous differences, she proceeded to Elba, made many attempts for his restoration, reconciled him with Lucien and Murat, and sent him all her jewelry, which was afterward found in Napoleon's carriage at Waterloo. She repeatedly applied for permission to share his captivity at St. Helena, and spent the rest of her life in great affliction, Napoleon's death giving an irretrievable blow to her shattered health. After a long residence in the Borghese palace in Rome, she joined her husband in Florence shortly before her death. The papal authorities treated her with great kindness, and she endeared herself to the people wherever she was by her patronage of letters and art and by her extensive charities. Canova's marble statue of Pauline (now said to be Queen Victoria's property) represents her as Venus Victrix. Her remains were transferred from Florence to Rome and buried in the Borghese chapel. (See BORGHESI.) **V. Caroline Marie Annouclade**, sister of the preceding, born in Ajaccio, March 26, 1782, died in Florence, May 18, 1839. She went with her mother to Paris, and was for some time under the tuition of Madame Campan at St. Germain. Murat was one of her many admirers, and Napoleon, over whom she exercised great influence, selected him as her husband. They were married on Jan. 20, 1800, and Murat successively became grand duke of Cleves and Berg (1806) and king of Naples (1808). Superior to her husband in administrative talent, she marked her accession to power as regent in her husband's absence, by recalling political exiles and releasing prisoners of state, and by a felicitous

selection of upright and able ministers. She promoted science, letters, and art, improved the material and moral condition of the Neapolitans, established several lyceums and a female seminary, and had extensive excavations made, especially at Pompeii, which brought to light many remarkable monuments. She also displayed great courage, especially in 1809, when she animated the drooping spirit of her subjects by exposing herself on the quay within reach of the fire of an English fleet. Her domineering nature, however, brought her into collision with Maria Louisa, and Talleyrand described her as a handsome woman with the head of Cromwell. Alienated from the emperor's court, she sided against him by joining her husband's secret negotiations with Austria and England. After the disasters which overwhelmed Murat, she took leave of him May 20, 1815, remained in Naples as regent, and invoked the assistance of English marines and the Austrian squadron for the repression of anarchy. She finally left Naples on board an English vessel in company with three of her former ministers, including Macdonald; on her way to Trieste she met the ship which was conveying Ferdinand, the restored king of Naples, to his capital. The emperor of Austria objected to her residing in Trieste, but permitted her to establish her domicile near Vienna, where she assumed the name of Countess Lipona—an anagram of Napoli or Naples. While here she accidentally learned the tragic end of her husband, after which she contracted a secret marriage with Gen. Macdonald, who had never left her since their departure from Naples. Despoiled of her vast personal property, she was eventually obliged to dispose of her estate near Vienna, and to join her daughters in Italy. Her claims upon the Élysée Bourbon and Neuilly palaces were rejected by France, but an annual allowance of 100,000 francs was granted to her by the chambers shortly before her death. She bore to Murat two sons and two daughters. (See MURAT.)

BONAPARTE. I. Jérôme, king of Westphalia, youngest brother of Napoleon I., born in Ajaccio, Nov. 15, 1784, died at Villegien, near Paris, June 24, 1860. He was educated at the college of Juilly, entered the army as a private in 1800, and soon afterward joined the naval service in the Mediterranean, and in 1801 the expedition to Santo Domingo, rising to the grade of lieutenant. In 1803, while on his return to France by way of the United States, where he was introduced to President Jefferson, he fell in love with Miss Elizabeth Patterson, the daughter of an eminent and wealthy Baltimore merchant, a young lady of great beauty, then in her 18th year. He deputed the Spanish minister in Washington to solicit her hand, and despite the protest of the French consul and the reluctance of the Pattersons, he married her on Dec. 24, 1803. The contract had been carefully drawn by Alexander J. Dallas, and the ceremony was performed

by the Roman Catholic Bishop Carroll of Baltimore, brother of Charles Carroll. They resided in the United States till March, 1805. While they were on their way to France Jérôme's mother entered a legal protest against the marriage, as contracted by her son during his minority without her consent and without legal publication of the banns in France. This was done at the bidding of Napoleon, who had in vain applied to Pope Pius VII. to cancel the marriage, but had from the first prohibited its registration, declaring it null and void and the prospective offspring illegitimate. The municipal authorities of Paris subsequently issued a decree to the same purport, and Jérôme and his wife were forbidden to enter France. They landed at Lisbon, and Jérôme had an interview with Napoleon at Alessandria, Piedmont, May 6, but without succeeding in reconciling him to his marriage. His wife, who had left Lisbon for Amsterdam, was not permitted to land there, and was obliged to sail at once for England, where in July, 1805, she gave birth to a son. Jérôme had in the meanwhile been permitted to reënter the naval service, and as commander of a French squadron he obtained from the dey of Algiers the liberation of several hundreds of French and Genoese captives, whom in August he brought safely to Genoa, despite English cruisers. Napoleon promoted him to a higher command under Admiral Willaumez on an expedition to the French possessions in the West Indies; but being overtaken by a storm, many of the vessels were scattered, the admiral making for American ports. Jérôme remained at his post, and with some of the ships succeeded in destroying several English vessels, and on Aug. 26, 1806, reached with a number of captives a small and almost inaccessible port on the coast of Brittany, having barely escaped capture by the British squadron under Lord Keith. This exploit won for him the rank of rear admiral, but he soon left the naval for the military service with the rank of brigadier general. At the same time he was recognized as a French prince, and subsequently (Sept. 24, 1806) the senate made him successor to the throne in the event of Napoleon's leaving no male issue. He commanded a body of Würtembergers and Bavarians in the Prussian war of 1806-'7, gaining some successes in Silesia, and was rewarded with the grade of general of division, March 14, 1807, and after the peace of Tilsit with the crown of Westphalia, which was erected into a kingdom, with Cassel as capital, Aug. 18. In the same month he married the princess Catharine, daughter of the king of Würtemberg, an alliance forced upon him by Napoleon, though he was much attached to his first wife, and had repeatedly urged the emperor to recognize her. But he never saw her again after her departure for England, excepting, as alleged, casually, years afterward in the picture gallery of the Pitti palace in Florence, when Jérôme started

aside on beholding her, and was overheard to say to Catharine, "That lady is my former wife," after which he left the gallery and departed next morning from Florence. After his accession to the throne of Westphalia, he appointed several learned men as ministers, reopened the university of Halle, emancipated the Jews, and introduced the *Code Napoléon*; but his rule was in other respects marked by shocking levity and prodigality, and politically he was nothing more than the deputy or viceroy of the emperor. In 1809, during the war with Austria, he promptly quelled the insurrectionary spirit in his kingdom, and proceeded with 20,000 troops to Saxony, entering Dresden Dec. 1. In the campaign against Russia, in 1812, he led a corps of Germans, and distinguished himself by bravery; but having been guilty of some neglect which disconcerted the plans of Napoleon, he was severely reprimanded by him, and went home in anger. In October, 1813, when the French were driven from Germany, he went to Paris. He was expelled from France in 1814, and was arrested with his wife by a body of the allies, but they were speedily released. He then went to Switzerland, and afterward resided in Gratz and in Trieste. On learning the emperor's return from Elba he hastened to Paris, became a member of the chamber of peers, and fought at Ligny and Waterloo, displaying a capacity and a bravery which made Napoleon say to him, "*Mon frère, je vous ai connu trop tard.*" He afterward returned to Paris, and the Würtemberg envoy holding out to him the prospect of a cordial reception, he proceeded to that country, but was arrested at the frontier and compelled to sign a convention, the terms of which made him almost a prisoner of the king of Würtemberg; and indeed on his arrival at Göppingen he was treated as such. The château of Ellwangen was assigned to him as a residence, where he remained with his family until about July, 1816, when he was permitted to leave; and on arriving at Augsburg he was surprised by receiving from the king a patent of nobility creating him prince of Montfort, which he returned under protest to his brother-in-law, the crown prince. He then spent some time near Vienna with the ex-queen Caroline, and here they heard of the death of his father-in-law and of his will, by which Jérôme's wife, who had already received her dowry of 200,000 francs, was not provided for beyond her share of 150,000 francs from her mother's estate. Jérôme having been unable to recover 1,200,000 francs which he had deposited with a banker in Paris, and the marquis de Maubreuil having robbed his wife while she was still in France of all her jewelry and of 80,000 francs in money besides, his position became embarrassing; and toward the close of 1819 he could hardly defray his travelling expenses on his way to Trieste for the restoration of his son's health. In the following year, however, he obtained judgment against his Paris

banker. He resided in Rome till 1831, when he removed to Florence, and afterward to Lausanne, where his devoted and accomplished wife died, Nov. 28, 1835. At the end of 1847 he was permitted to reside in Paris, and after the revolution of February, 1848, he was restored to his military rank and appointed governor of the Invalides (Dec. 23) and marshal (Jan. 1, 1850). In January, 1852, he became president of the imperial senate, but retired toward the end of that year, after delivering a remarkable speech on the restoration of the empire. The *palais royal* and the palace of Meudon were placed at his disposal, the right of succession to the throne was accorded to him and to his son, and he presided occasionally over cabinet councils in place of the emperor. He died from a pulmonary inflammation, which had prostrated him since December, 1859, and was buried with great pomp in the church of the Invalides.—**Jérôme's** surviving first wife, Madame Patterson, as she was called in France, having spent several years in Europe in unavailing efforts for the legal recognition of her marriage, has ever since resided as Mrs. Patterson-Bonaparte in Baltimore, where she is much respected; and though smarting under an irretrievable wrong, she never ceased to cherish the memory of the husband who deserted her. She was engaged in 1872 in completing her autobiography. **II. Jerome Napoleon**, only child of the preceding by his first wife, born at Camberwell, England, July 7, 1805, died in Baltimore, June 17, 1870. He was educated in Europe and the United States, and graduated at Harvard college in 1826. He studied law, but never practised, and in early life married Miss Susan Mary Williams, daughter of an opulent citizen originally of Roxbury, Mass. She brought him a large fortune, which in addition to his own property made him one of the richest men of Baltimore; and he devoted himself to the management of his estate and to agricultural pursuits. He received a handsome allowance from his father, with whom he was on terms of intimacy in his several visits to Europe. Louis Philippe permitted him to reside for a short time in Paris, but only under the name of Patterson; yet he attracted much attention by his striking likeness to his uncle Napoleon. In 1852 a family council decided in favor of his assuming the name of Bonaparte, but without being regarded as belonging to the imperial family; and at the invitation of Napoleon III. he several times visited him in Paris with his son. After his father's death in 1860, the Patterson claim was again brought before the French courts; but, although Berryer pleaded the cause, the decision in 1861 was again adverse to the recognition of Jerome as the legitimate son of the king of Westphalia. Mr. Bonaparte never became naturalized in the United States, and proudly called himself a French citizen.—His only son, **JEROME NAPOLEON**, born in 1832, a graduate of West Point

(1852), became an officer in the French army in 1854, and served in the Crimea, Algeria, Italy, and France till the fall of the empire. He then returned to the United States, and in 1872 he married at Newport, R. I., a lady of Boston. **III. Jérôme Napoleon**, son of King Jérôme by his second wife, Catharine of Würtemberg, born Aug. 24, 1814, died in Florence, May 12, 1847. He was an officer in the Würtemberg army till 1840, when ill health compelled his retirement. **IV. Napoléon Joseph Charles Paul**, popularly known as Prince Napoléon, second son of Jérôme and Catharine of Würtemberg, born in Trieste, Sept. 9, 1822. His education, commenced in Rome, was completed in Geneva and at Arenenberg, where his cousin, the future Napoleon III., was his tutor. His uncle, the king of Würtemberg, provided for his military training at Ludwigsburg, and after remaining here for four years he travelled extensively and spent some time in Spain. His resemblance to the first Napoleon attracted attention everywhere, and Béranger describes him, in allusion to his obesity, as a genuine Napoleon medal dipped in German fat (*une vraie médaille Napoléonienne trempée dans de la graisse allemande*). A permission granted him by Louis Philippe in 1845 to reside in Paris was withdrawn after four months, mainly in consequence of his alleged understanding with revolutionists; but in 1847 he was allowed to remain in France with his father, and he made himself conspicuous on Feb. 24, 1848, by his eager support of the revolution. In 1848 he was elected deputy from Corsica to the constituent assembly, and in 1849 from the department of the Sarthe to the legislative assembly. The less liberal complexion of the latter body induced him to accept from Louis Napoleon the mission to Spain; but he had hardly reached Madrid when, on hearing of the reactionary educational measures proposed by Falloux, he hastily returned to the assembly, and was deprived of his office as minister for having deserted his post. He now became noted for his violent opposition, and was called *le prince de la Montagne*. In 1850, when Thiers applied the term *vile multitude* to those who were to be disfranchised, he vindicated popular rights in an inflammatory speech; but he kept quiet for a time after the *coup d'état* of Dec. 2, 1851. On the establishment of the second empire in 1852 he took his seat in the senate and council of state as an imperial prince, with the right of succession to the throne. At the same time he was made general of division, though he had never seen military service; and at the opening of the Crimean war he was placed in command of a reserve corps at the Alma and at Inkerman. He was soon recalled, ostensibly on account of ill health. His adversaries questioned his bravery and capacity, while his partisans ascribed his abrupt return to civil life to his having insisted with characteristic vehemence upon using the war against Russia for the liberation

of Poland. He displayed considerable talent and activity as president of the imperial commission of the exposition of 1855, and in a scientific maritime excursion to the coasts of Scotland, Iceland, and Greenland in 1856, and was admitted to the academy of fine arts. In 1857 he acquitted himself successfully of a diplomatic mission by prevailing upon Prussia to relinquish her claims upon Neuchâtel in favor of Switzerland, putting an end to that contest. In 1858 he was appointed to the newly created ministry of Algerian and colonial affairs, and held that office about nine months. His marriage on Jan. 30, 1859, with the princess Clotilde, daughter of King Victor Emanuel, was speedily followed by the Franco-Italian war against Austria, during which he was sent to Tuscany at the head of the fifth army corps; but though he crossed the Apennines by forced marches, he reached headquarters only to witness the conclusion of the preliminary treaty of peace of Villafranca, for the carrying out of which he was sent to Verona. In 1861 he went with his yacht to the United States, and leaving the princess Clotilde with the duchess d'Abrantès at New York, proceeded to Washington, where Secretary Seward presented him to President Lincoln. He then visited Beauregard's headquarters at Manassas, and pushed as far as Richmond, escorted by the French minister Mercier. He was accompanied by Maurice Sand, the son of his intimate friend Mme. Dudevant (George Sand), and others; and he often expressed his sympathies with the cause of the Union and of slavery abolition. After his return he made in 1862 and 1863 remarkable speeches in the senate against the temporal power of the papacy and in favor of Polish nationality. In 1863 he visited the Suez canal, of which enterprise he became an advocate. At the inauguration of the statue of Napoleon I. in Ajaccio in 1865, he made a sensational oration, full of democratic sentiments, which proved still less palatable than his previous speeches to the emperor, who was then in Algeria, and from thence addressed an official reprimand to the prince. The latter immediately threw up all his public functions, including his membership of the council of regency, his opposition to the temporal power of the pope having converted the empress Eugénie, who had never been his friend, into his inveterate enemy. But he speedily regained the confidence of the emperor, who apparently regarded his vagaries as harmless, and even in some respects as useful. In 1868 he visited the North German states, and a political object was ascribed to this as to his other journeys in that year, especially as he occasionally received official deputations and was fond of assuming the attitude of a sovereign prince. Though he constantly coquetted with the ultra radicals, they never ceased to regard him as in reality an imperialist, possibly desirous of supplanting his cousin; while the emperor himself even refrained from rebuking his renewed violence in

1869, though his speech on that occasion was publicly disavowed by Rouher, president of the senate. Prince Napoleon had long been nicknamed Plon-Plon, his ambition as well as his attempt to reconcile imperialistic with extreme liberal institutions subjecting him to criticism, to which the grotesque contrast between his impetuous demonstrations and placid appearance added a tinge of the ridiculous. After the outbreak of the Franco-German war, he made unavailing efforts to draw Italy into the contest against Prussia, and at the close of 1871 he declined to accept an election to the general council of Corsica. In October, 1872, he was ordered to leave Paris, and on his resisting he was forcibly expelled. The prince instituted legal proceedings against the prefect and commissary of police who arrested him in the house of his friend M. Richard, claiming 200,000 francs damages. He afterward returned to his château of Frangins near Geneva with his wife and children, consisting of two sons, born in 1862 and 1864, and a daughter, in 1866. They occasionally reside also in their mansion at Milan. **V. Mathilde** *Lettitia Wilhelmine*, sister of the preceding, popularly known as Princess Mathilde, born in Trieste, May 27, 1820. She was early distinguished by her literary and artistic tastes, and in 1841 married in Florence the Russian count Anatol Demidoff, whom the grand duke of Tuscany made prince of San Donato. He having agreed to bring up the prospective children in the Roman Catholic faith, the emperor Nicholas deprived him of his office of chamberlain. But they had no issue, and when Mathilde went to St. Petersburg the czar became her friend, and he corresponded with her till the Crimean war; and on her separation in 1845 from her husband, he insisted upon his settling on his wife an annuity of 200,000 rubles. The princess Mathilde presided over the household of Louis Napoleon previous to his marriage with Eugénie, and afterward continued to occupy a prominent position at the imperial court until the Franco-German war, when the downfall of her cousin deprived her of her large endowments; and the death of her former husband in April, 1870, also cut off the income which she had derived from him. Her palace in Paris and her summer residence at St. Gratien, near the lake of Enghien, were the most distinguished literary and artistic centres of the second empire; and she excels as an artist, as is attested by her fine paintings and etchings. After the death of Sainte-Beuve in 1869, the newspapers engaged in a lively controversy about her letters to him; and her special favorite was Théophile Gautier, whose funeral she attended in October, 1872, President Thiers having permitted her to continue to reside in Paris.

BONAPARTE, Joseph, successively king of Naples and of Spain, eldest brother of Napoleon I., born at Corte, Corsica, Jan. 7, 1768, died in Florence, July 28, 1844. The grand duke of Tuscany having recommended Charles Bonaparte

to his sister, the queen of France, he gained admission for his son Joseph to the college of Autun, destining him for the church. Joseph, however, agreed with Napoleon to become a soldier; but the father prevailed upon him shortly before his death to relinquish this project, and to devote himself to the task devolving on him as the eldest son of attending to the education and prosperity of his younger brothers and sisters. Joseph having completed his education at the university of Pisa, the grand duke of Tuscany wished to attach him to his service, but he preferred to rejoin his family in Corsica. In June, 1788, he was admitted as advocate to the superior council at Bastia, and he became one of the most active and influential members of the municipality. He was an early and zealous supporter of the French revolution of 1789, became president of his district, published a pamphlet on the new French constitution, was a member of the committee appointed to invite Paoli to Corsica, and became his secretary in the Corsican administration. During the English invasion of the island Joseph, who had been commander of militia, served at Toulon at the same time with his brother Napoleon. On Aug. 1, 1794, he married at Marseilles Marie Julie Olary, daughter of a rich merchant, and whose younger sister became in 1798 the wife of Bernadotte and afterward queen of Sweden. In 1796 he followed Napoleon to Italy as military commissary of his army, and was sent by him to Paris with Junot to deliver his trophies to the directory. Shortly afterward he was sent with a body of men to Corsica against the English; but they having evacuated the island before his arrival, he rejoined Napoleon, who procured for him the appointment of French envoy in Parma, which he exchanged in 1797 for that of French minister in Rome. His course during the commotions in that city in 1798 being approved by the directory, the mission to Berlin was tendered to him; but he preferred joining the council of 500 as member elect from Corsica, his presence in Paris enabling him to watch over the interests of Napoleon, to whom he sent his Greek friend Bourbaki to urge his immediate return from Egypt. He cooperated with Napoleon in the events of the 18th Brumaire, introducing Moreau to him, and through the medium of Cabanis making the first overtures to Sieyès. He declined a place in the cabinet, but accepted a seat in the tribunate and in the council of state, and contributed essentially to the popularization of the new consular government by assisting Napoleon with his advice, and by rallying round him many supporters, his amenity of manners and conciliatory disposition making friends for him in almost all classes of society. The same characteristics secured his success as the negotiator of the treaty of peace with the United States in 1800, with Germany at Lunéville in 1801, and with Great Britain at Amiens in 1802; and subse-

quently in concluding the concordat with the Roman see. When assuming the imperial dignity, Napoleon offered the crown of Lombardy to Joseph, who however preferred to remain in France as the presumptive successor to the new throne. In 1805 he was prevailed upon by his brother to accept a military position; but as the latter had to leave for the seat of war, Joseph remained in Paris to share with Cambacérès in the administration of the government. After the victorious return of Napoleon from Austerlitz, Joseph was sent with an army to Naples, entering the city in February, 1806, and assuming the title of king of Naples, according to the wishes of Napoleon, which had now become laws even for Joseph, to whom up to that time he had invariably shown great deference. The cares of the throne were not congenial to Joseph's quiet disposition; and they were made the more harassing by the futile attempts to conquer Sicily and by other internal complications, and especially by the interference of his brother with his conciliatory measures. Yet he became attached to the genial climate and to the people of Naples; and after having reigned over them about two years with great mildness and with much solicitude for their prosperity, it was with reluctance, and only in obedience to his brother's inexorable will, that in 1808 he exchanged the throne of Naples for that of Spain. In an interview with Napoleon at Bayonne, Joseph insisted upon being recognized as king by the Spaniards previous to his departure for their country, and Napoleon at once had a junta convened (June 15), which lost no time in giving the prescribed recognition. The new monarch left for Madrid, but a day after his arrival there (July 20) he informed Napoleon of his deception and of the unconquerable hostility of the Spaniards. If left to himself, he might perhaps have made his rule acceptable to them; but he was compelled to govern Spain, as he had been to govern Naples, not in the interest of the nation, but according to the dictates of Napoleon, who disdained to listen to Joseph's repeated remonstrances, suggestions, and entreaties; neither would he allow him to relinquish the throne, though Joseph wished to be relieved from its burdens. Three times during his administration of five years he was driven by hostile armies from his capital, the last time, in 1813, never to return. After transferring (July 12) the command of the army to Soult, Joseph retired to a château near Bayonne, and soon afterward he rejoined his family at Mortfontaine, near Paris. On Dec. 29 he wrote to Napoleon placing himself at his disposal, but yet expressing unwillingness to desert his duties as king of Spain. The emperor in January, 1814, made him lieutenant general of the empire in his absence, with large military and civil prerogatives as the head of the regency under Maria Louisa. In this capacity, when the allied army invested Paris in March, 1814, he authorized Marmont and

Mortier to treat for a suspension of hostilities, and subsequently consented to a capitulation. He then joined Maria Louisa and her son at Blois, attempted in vain to rejoin Napoleon at Fontainebleau, and went to Switzerland, where he purchased the château of Prangins on the lake of Geneva. On hearing of the emperor's landing at Cannes, Joseph hastened to Paris, and endeavored to gain the support of Lafayette, Mme. de Staël, Benjamin Constant, and his other personal friends, for his brother's last desperate attempt at restoration, by holding out the promise of a constitutional form of government. After the battle of Waterloo he met Napoleon for the last time, June 29, 1815, and in vain proposed to take his place as prisoner, by passing himself off for him. Napoleon still hoping to be able to escape to the United States, the two brothers pledged themselves to meet there. While the emperor was conveyed to St. Helena, Joseph embarked at Royan, July 25, under the name of Count de Survilliers, for New York. He purchased a house in Philadelphia, where he lived during the winter, and extensive grounds and a mansion called Point Breeze, near Bordentown, N. J., where he generally spent his summers. An act was passed in 1817 by the legislature of New Jersey to enable him, as an alien, to hold real estate; and at his request a similar act was passed in 1825 by the state of New York, where he resided some time in a secluded mansion on the edge of the great northern wilderness. He endeared himself to Americans by his benevolence, affability, and accomplishments; and he was elected to many philanthropical and learned associations. His wife was prevented by her delicate health from joining him; but his two daughters and his son-in-law, the prince of Canino, lived with him in the United States. Among his other faithful companions was O'Farrell, formerly one of his ministers in Spain. His exile was cheered by the visits of Lafayette and other distinguished personages, but it was deeply saddened in 1821 by the death of Napoleon, to whom Joseph had never ceased to be tenderly devoted. As chief of the Bonaparte family, he ineffectually exerted himself after the revolution of July, 1830, for the recognition of the claims of Napoleon II. to the throne of France, and protested against the accession of any other dynasty. In 1832, on hearing of the duke of Reichstadt's illness, he went to Europe; but being informed of his death at Liverpool, he remained in England. In 1834 he joined his brother Lucien in a protest against the banishment of their family from France, disclaiming all unpatriotic and ambitious designs, and declaring their submission to the popular will. In 1837 he returned to the United States, but in 1839 again went to England. Some time after his second arrival in London he was struck with paralysis, and sought relief in vain at Wildbad, Wurtemberg. In order to escape from the English climate and to rejoin his family, he wished to proceed

to Italy. Even in 1841, however, he could only obtain the consent of the king of Sardinia to his residing in Genoa; but this example was soon followed by the grand duke of Tuscany, and he spent the rest of his life with his family in Florence. Joseph was not made for camps or thrones; his ambition was moderate, and he found the main sources of happiness in domestic and social life, and in the gratification of his literary and artistic tastes. His presence was elegant and courtly, and his manners were singularly winning. The correspondence between himself and Napoleon I., which has been published since his death, reveals the confidential intercourse of the two brothers, and throws considerable light upon the details of important events and transactions. Joseph presented the various insignia of the legion of honor which had been worn by Napoleon to the French government, and many pictures from the collection of his uncle Cardinal Fesch to Corsican towns. The museum of Versailles contains a marble statue of Joseph, by Delaistre; a bust, by Bartolini; and a portrait of him by Gérard. See *Mémoires et correspondance politique et militaire du roi Joseph*, by Du Casse (10 vols., Paris, 1853-'55; an English selection from the same, 2 vols., New York, 1856), and *Mémoires*, by Miot de Melito (3 vols., Paris, 1858).—His wife died in Florence, April 7, 1845. Their elder daughter, ZÉNAÏDE CHARLOTTE JULIE, married her cousin the prince of Canino, and died in Italy in 1854. The younger daughter, CHARLOTTE, born in Paris, Oct. 31, 1802, married her cousin, the second son of Louis, had no children, became a widow in 1831, and died at Sarzana, Italy, March 2, 1839.

BONAPARTE. I. Louis, king of Holland, third brother of Napoleon, born in Ajaccio in September, 1778, died in Leghorn, July 25, 1846. Napoleon wished him to study military science at Châlons, but this project was not carried out, and he subsequently served under his brother in Italy and Egypt, and displayed bravery in various engagements, especially at the battle of Arcole. He cooperated with Napoleon on the 18th Brumaire, and rose to the rank of colonel. He was in love with a schoolmate of his sister Caroline, and consented with great reluctance, at the urgent request of Napoleon and Josephine, to marry Hortense, Josephine's daughter. (See BEAUFARNAIS.) Hortense was equally indifferent to the alliance, which proved unhappy. In 1804 he was made general and councillor of state, and after the establishment of the empire he became prince and constable, governor general of the transalpine departments, and military commander of Paris as successor of Murat, who took the place first destined to Louis at the head of the reserve in the proposed expedition against England. Against the wishes of Louis, the crown of Holland was forced upon him by Napoleon, and he was proclaimed king at Saint Cloud, June 5, 1806. Napoleon, in replying to the Dutch admiral Verhuel's discourse on that occasion,

intimated to Louis that, although king of Holland, he should never cease to be a Frenchman; but Louis after his accession to the throne proposed to devote himself exclusively to the interests of his kingdom, and hence arose interminable difficulties with Napoleon. Louis promoted science, letters, art, the construction of canals and dikes, a vast system of drainage, and various other ameliorations. He resisted Napoleon's design of converting the Dutch army and nation into tools for his conquests and ambition. But while Louis lost no opportunity to propitiate Holland, Hortense sided with Napoleon, and otherwise gave Louis serious cause for deploring their ill-fated union, though she imparted brilliancy to the court of the Hague. The death of their first-born child, *Napoléon Louis Charles*, in 1807, increased his unhappiness. In the autumn of that year he became altogether estranged from his wife, and she went to Paris, where on April 20, 1808, she gave birth to the future *Napoleon III.* Louis transferred his capital from the Hague to Utrecht, and eventually to Amsterdam. His relations with Napoleon became still more embittered by the injury which the blockade against England inflicted upon Dutch commerce. Louis resisted this measure as long as possible, and upon finally submitting to it he closed the Dutch ports not only against English but all foreign shipping. The emperor charged him with playing into the hands of England, and allowing Holland to be used as a neutral ground for his enemies. Louis had a stormy interview with Napoleon in Paris in December, 1809; and during his residence in that city he was almost reduced to the condition of a prisoner, the emperor insisting upon regarding Holland as a sort of French dependency, and preventing Louis from returning to his kingdom. On the latter's taking measures to baffle the occupation of Amsterdam by French troops, Napoleon threatened him with the annexation of Holland. Finally he was compelled to yield so far as to interdict all commercial relations with England, to withdraw the privileges granted to the Dutch nobility, and to organize a powerful navy and army to support France against England in case of need. After assisting at Napoleon's marriage with *Maria Louisa*, having been previously obliged to sanction his divorce from *Josephine*, Louis returned to Amsterdam in April, 1810, by way of *Aix-la-Chapelle*; while Hortense, ordered by the emperor to resume her position as queen, took the direct route to Holland, but remained only for a short time, Louis taking little or no notice of her departure. Having been compelled to ratify, though only conditionally, a treaty signed by *Admiral Verhuel*, authorizing small French garrisons in several localities, and his subsequent protests against Napoleon's increasing usurpations in Holland proving unavailing, he was finally obliged to abdicate in favor of his eldest surviving son *Napoléon Louis*, appointing Hortense as regent, and left Amsterdam July 1, 1810, a short time before

the annexation of Holland to France. But he never ceased to protest against this measure, and to assert his claims and those of his family to the Dutch throne. He took up his residence at *Teplitz*, July 9, under the name of *Count St. Leu*. Resisting Napoleon's order, conveyed to him through *Decazes*, to return to France, he left for *Gratz*, and on Dec. 30 declined the estates offered to him by the senate in compensation for his throne, and also forbade Hortense to accept the endowment. In August, 1813, after the outbreak of war between France and Austria, he left the latter country for Switzerland, having repeatedly but in vain applied to Napoleon for the restoration of his kingdom, the emperor finally declaring that he would rather see the house of Orange restored than his brother. Louis made an unsuccessful effort to be reinstated by the people of Holland during their war of independence, and afterward went to Paris. Napoleon received him coldly, and did not wish him to reside in the capital unless he would relinquish all ideas of dominion in Holland, and would sustain his own power, in which case he would be acknowledged as a French prince and constable of the empire. Louis nevertheless remained in Paris, maintaining his pretensions with characteristic obstinacy, and was the only one of Napoleon's brothers who durst defy him to the last. After the overthrow of the emperor in 1814, he joined *Maria Louisa*, who had left Paris against his advice; the allies permitted him to reside in France, but he would not witness the humiliation of his country, and went to *Lausanne*. Hortense having obtained from *Louis XVIII.*, through the medium of the czar *Alexander*, a grant of the domain of *St. Leu*, with the title of duchess, Louis spurned the king's letters patent, issued May 30, 1814, which raised *St. Leu* to a duchy; and he also scorned to accept his share of the annuity of 2,500,000 francs which the treaty of *Fontainebleau* had provided for him and the other princes of the Bonaparte family. His protest to that effect was published at *Aarau* on Aug. 2, 1814, and soon after he left Switzerland for Rome. Hortense refusing to surrender the custody of their son *Napoléon Louis*, he was obliged to have recourse to the tribunal at Paris, which conceded this right to him March 7, 1815; after which he retired to Florence with the young prince, who died at *Forli* in 1831. His health, affected by this and other sorrows, was soon hopelessly impaired by apoplectic fits, which culminated in partial paralysis. The abortive attempts of his youngest son *Louis Napoléon* at *Strasburg* (1836) and *Boulogne* (1840) became new sources of chagrin. He implored his personal friends among the members of the French cabinet to intercede with *Louis Philippe* not to deprive him of his son's society during the last moments of his life. But the king insisting upon guarantees which the captive prince would not give, Louis despaired of seeing him again. When he was apprised of his

escape from Ham, though in a dying condition, he hastened from Florence to Leghorn to meet him, but arrived only to be informed of his son's inability to procure a passport from England for Italy. This disappointment brought on a fit from which he died, unattended by any member of his family. He was buried in the church of Santa Croce, and his remains were subsequently transferred to the church of St. Leu in Paris. Despite his life-long difficulties with Louis, the emperor gave precedence in his will to his children over those of Joseph and Lucien in the right of succession, and also pardoned him for what he denounced as libellous assertions in the *Documents historiques et réflexions sur le gouvernement de la Hollande* (3 vols., Paris and London, 1820), the most important publication by Louis, and which throws much light upon his and Napoleon's career. He was also the author of several volumes of poetry, of a novel descriptive of Dutch life and manners (*Marie, ou les peines d'amour*, 3 vols.; 2d ed., under the title of *Marie, ou les Hollandaises* 1814), and of a *Mémoire sur la versification* (Paris, 1814), which obtained from the institute a prize offered by himself for the best essay on versification. He afterward enlarged this work (2 vols., Rome, 1825-'6), adding adaptations of *Euth et Noëmi*, an opera, *Lucrèce*, a tragedy, and Molière's *L'Avare*, as specimens of Greek and Latin forms of versification which he wished to see adopted in French poetry. His other writings include *Histoire du parlement anglais depuis son origine jusqu'en l'an VII*, with autograph notes by Napoleon (Paris, 1820); *Réponses à Sir Walter Scott sur son Histoire de Napoléon* (1828-'9); and *Observations sur l'Histoire de Napoléon par Norvins* (1834). The last surviving son of Louis and Hortense was the late emperor Napoleon III. (See BONAPARTE, NAPOLEON III.)

II. Napoléon Louis, second son of the preceding, born in Paris, Oct. 11, 1804, died in Forlì, Italy, March 17, 1831. He was the first of the Bonaparte princes whose name was inscribed on the official records; he was baptized by Pope Pius VII., and Napoleon I. and Madame Lætitia were his sponsors. The death of his brother made him heir presumptive to the Dutch throne, and while Hortense was regent he was for a short time recognized as king of Holland. The emperor made him in 1809 grand duke of Cleves and Berg, and his mother had him educated by the abbé Bertrand. In conformity with the decisions of the tribunals, he was subsequently taken away from her to join his father in Italy. In 1827 he married his cousin Charlotte, the younger daughter of Joseph, ex-king of Spain. He became an ardent liberal, and during the revolutionary outbreak of 1831 he and his brother Louis Napoléon organized the defensive operations of the Italian patriots on the line from Foligno to Civita Castellana, and were about to seize the latter fort and set free the prisoners of state detained there, when their parents dissuaded them

from compromising the Italian cause by giving to the French a pretext for deserting it. They went thereupon to Bologna, and when that city was occupied by the Austrians, they removed to Forlì, where Prince Napoléon Louis died of the measles. He was noted for his scientific attainments and his mechanical inventions. He established a paper manufactory on a plan of his own, published an essay on balloons, translated into French the "History of the Sacking of Rome," by his reputed ancestor Jacopo Buonaparte (Florence, 1829), and published some other writings.

BONAPARTE. I. Lucien, prince of Canino, second brother of Napoleon, born in Ajaccio, March 21, 1775, died in Viterbo, June 29, 1840. He attended with his brother Joseph the college of Autun for nearly two years, and afterward studied at the military school of Brienne and at the seminary of Aix in Provence. He then lived some time with his uncle, the future cardinal Fesch, and in 1792 returned to Corsica. Lucien was an ardent supporter of the revolution, and Paoli called him his little Tacitus. After Paoli's rupture with France in 1793 Lucien abandoned him, and went at the head of a deputation to Paris to solicit assistance against him and against the English. Subsequently he became connected with the commissary department at St. Maximin, and exerted much influence in that little town, as president of the popular society and the revolutionary committee, in preventing political excesses. He was nevertheless arrested after the fall of Robespierre, while he was acting as military inspector in the vicinity of Certe, and released only after six weeks' imprisonment through Napoleon's influence with Barras, who subsequently appointed him commissary of war. About the same time he married a poor girl of Provence. In 1798 he was elected deputy to the council of 500, of which he became president after Napoleon's return from Egypt. Having been a prominent supporter of the constitutional reforms projected by Sieyès, he aided in securing his coöperation for the *coup d'état* of the 18th Brumaire, and was one of the most active in its execution. During the stormy scenes in the council of 500 he left the chair under the protection of Napoleon's grenadiers. He was appointed by the first consul to the newly created senate, but at his request he became minister of the interior as successor of Laplace, who took Lucien's seat in the senate; and the administrative centralization of France was initiated during his tenure of office. He reestablished the official organ, the *Mercure de France*, and promoted letters and arts; but he was too independent to suit his brother, and his relations with him became still more embittered through Fouché, who taunted Lucien with his improvident course and with his illicit relations with the actress Mézeral, and falsely charged him with conspiring against the first consul. Lucien was removed from the ministry and sent as ambassador to Madrid. Here he ingratiated

himself with Godoy and Charles IV., and in March, 1801, secured the alliance of Spain with France in the attack upon Portugal. But he subsequently allowed himself to be outwitted by Godoy, incurring the censure of Napoleon, who charged him with having played into the hands of England, but ordered him to remain in Spain till after the conclusion of the treaties of Badajoz and Amiens, although Lucien had at once tendered his resignation. On his return to Paris, early in 1802, he became a member of the tribunate. He supported the conclusion of the concordat, and aided his brother in being made consul for life. Elected as the deputy of the tribunate to the grand council of the legion of honor, of which he was one of the founders, he became in this capacity an *ex officio* member of the senate. The institute was reorganized and enlarged under his auspices, and both he and his second wife, whom he married in 1802, were popular in literary and general society; but this alliance was so displeasing to Napoleon that Lucien, who never sacrificed his dignity and independence, broke off all relations with him and left France in the spring of 1804. He went to Milan, then to Pesaro, and eventually took up his residence in a magnificent palace in Rome, devoting himself to literary and archaeological labors, in which he became so much absorbed that Count Miot, charged by Napoleon in 1806 to offer a crown to Lucien if he would repudiate his wife, did not even venture to broach the subject. In December, 1807, Napoleon sought an interview with him at Mantua, and offered him a crown, the hand of the prince of Asturias for his daughter, and a duchy for his wife, provided he would divorce her. But Lucien spurned these tempting offers, and deemed it prudent to leave Rome in view of the emperor's increased exasperation, and to reside on his extensive estate near Viterbo, which the pope converted for his benefit into the principality of Canino. Lucien felt even here insecure against Napoleon, and embarked at Civita Vecchia Aug. 1, 1810, for the United States; but he was captured by an English cruiser and conveyed to Malta, and thence to England. Though Lucien was not connected with the empire, and Napoleon even had his name struck out of the imperial almanac, he was treated as a prisoner and detained at Ludlow castle, Wales. Shortly afterward, however, he was allowed to reside at Thorngrove, Worcestershire, where he remained till April, 1814, when he returned to Rome. As soon as he was apprised of the emperor's banishment to Elba, he became as generous to him in his adversity as he had been vehement in opposing his tyranny in his prosperity, and assisted him during the hundred days. After spending some time with his friend Mme. de Staël in Switzerland, he took up his official residence in the *palais royal* as an imperial prince; but the chamber of peers declined admitting him as such, recognizing him only as an ordinary member. He was installed among the

members of the government upon the emperor's departure for Waterloo. After the fatal issue of that battle his appeals to the chambers in favor of the preservation of the empire proved unavailing, and Lafayette gave him a crushing reply by referring to the vast hosts sacrificed to the emperor's ambition. He in vain advised his brother to dissolve the chambers, and on his second abdication he insisted upon his transferring the throne to Napoleon II., whose claims he also vindicated in the senate. He remained with Napoleon till the end of June, and subsequently twice proposed to share his captivity in St. Helena. Going to Italy, he was arrested at Turin, and released after three months on the intervention of the pope, to whose dominions he returned, to devote himself in his villa Russinella, near Frascati, to literary and archaeological labors. Béranger applying to him for assistance in 1808, Lucien immediately placed at his disposal his annual income from the academy, and the poet expressed his gratitude in the preface to his songs of 1833; but Lucien was excluded from the academy after the restoration, though he had been one of its benefactors. He published a description of his famous collection of Etruscan antiquities, and his other works include a novel, *La tribu indienne*, ou *Edouard et Stellina* (2 vols., Paris, 1799), which was translated into English and German; *Charlemagne, ou l'Eglise délivrée* (2 vols., London, 1814; English translation by Butler and Hodgson), and other poems; *La vérité sur les Cent Jours* (Paris, 1835); and his *Mémoires*, of which the first volume appeared in 1836, and an extract of the second volume was published by his widow in 1845 under the title, *Le 18 Brumaire*.—Lucien's first wife, CHRISTINE ELÉONORE BOYER, daughter of a hotel proprietor, died in Paris, May 14, 1800. She bore him two children: CHARLOTTE, born May 13, 1796, married in 1815 Prince Mario Gabrielli, and in 1842 the Roman physician Centamori, and died in Rome May 6, 1865. CHRISTINE EGYPTA, born in Paris, Oct. 19, 1798, married in 1818 the Swedish count Arved Posse, and in 1824 Lord Dudley Coufts Stuart, and died in Rome in May, 1847. Lucien's second wife (1802) and previous mistress was MARIE ALEXANDRINE CHARLOTTE LOUISE LAURENCE DE BLESCHAMP, who was divorced from her first husband, the wealthy stock broker Jouberton. She was an amiable and accomplished woman, and published a poem, *Batilde, reine des Francs* (Paris, 1820). She bore him four daughters and four sons. Of the former, JEANNE died shortly after her marriage with Count Honorati; MARIE married Count Vincenzo Valentini, who died in 1858; CONSTANCE became abbess of the convent of the Sacred Heart in Rome; and LÉTTITIA, born in Milan, Dec. 1, 1804, was the wife of Sir Thomas Wyse, for many years British ambassador in Athens, became a widow in 1862, and died March 15, 1871. One of her two daughters became in 1862 the wife of the Hungarian

general Turr, and the other, MARIE, after the death of her first husband, Frédéric Solms, in 1862, contracted a second marriage in 1863 with the Italian statesman Ratazzi. (See RATAZZI.) **II. Charles Lucien Jules Laurent**, prince of Canino and Musignano, a naturalist, son of the preceding, born in Paris, May 24, 1803, died there, July 29, 1857. He was educated in the universities of Italy. In 1822 he married at Brussels his cousin Zénaïde, the daughter of Joseph, ex-king of Spain. He joined his father-in-law in Philadelphia, and gained a high reputation as an ornithologist, which was increased by his subsequent labors after his return to Italy in 1828. On the death of his father in 1840 he inherited his princely titles, but continued to devote himself exclusively to scientific pursuits till 1847, when he touched upon politics at the scientific congress of Venice, and was expelled by the Austrian authorities. After a visit to London and Copenhagen he went to Rome, where he supported Pius IX. as long as he adhered to a progressive policy; but when the pope changed front and was eventually driven to Gaeta, the prince of Canino became a prominent leader of the revolutionists, was a member and vice president of the constituent assembly, and gallantly upheld the cause of the republic until the occupation of Rome by French troops, July 3, 1849, after which he left for France. Despite the warning given him at the frontier, he continued his journey toward Paris, and was arrested at Orleans by order of Louis Napoleon and conveyed to Havre, whence he sailed for England. In 1850, however, he was permitted to reside in Paris, where in 1854 he became director of the *jardin des plantes*. He was the founder and president of many scientific congresses in Italy, lectured before them on natural history, and was elected member of the academies of sciences of Upsal and Berlin, and correspondent of the French institute. He wrote extensively on American and European ornithology and other branches of natural history. Many of his writings are contained in academical annals and other periodical publications. His principal separate works are: "American Ornithology, or the Natural History of Birds inhabiting the United States, not given by Wilson" (4 vols. 4to, illustrated, Philadelphia, 1825-'33, with descriptions of over 100 new species of birds discovered by him); *Specchio comparativo delle ornithologie di Roma e di Filadelfia* (Pisa, 1827, establishing a comparison between European and American birds); and *Iconografia della fauna Italica* (3 vols., royal 4to, richly illustrated, Rome, 1838-'41). His latest and partly posthumous productions comprise *Catalogue des oiseaux d'Europe* (1 vol. 4to, Paris, 1856); *Iconographie des pigeons*, and in conjunction with M. de Pouancé *Iconographie des perroquets* (Paris, 1857-'9). A volume of "Memoirs of Himself" was published in New York in 1836.—His wife, an accomplished woman, who translated Schiller's

dramas and assisted her husband in his scientific labors, died in Italy, Aug. 8, 1854. She bore him twelve children, four of whom died young. The surviving five daughters became respectively the wives of Marquis Roccagiovine, Count Primoli, Count Campello, and Prince Placido Gabrielli. The eldest son, JOSEPH LUCIEN CHARLES NAPOLÉON, born in Philadelphia, Feb. 13, 1824, barely escaped assassination in Rome, Feb. 10, 1850, though he was not connected with politics, and died in that city, Sept. 2, 1865. He was succeeded as head of the family by his brother, LUCIEN LOUIS JOSEPH NAPOLÉON, born in Rome, Nov. 15, 1828. He was ordained as a priest in 1853, and is a great favorite of Pius IX., whose privy chamberlain he was till 1868, when he was made cardinal. Napoleon III. conferred upon him in 1865 the title of French prince and of highness, and during the existence of the second empire he was generally regarded as a Bonapartist candidate for the papacy. His only surviving brother is NAPOLÉON GRÉGOIRE JACQUES PHILIPPE, born in Rome, Feb. 5, 1839. He married in 1859 the Italian princess Ruspoli, and the title of highness was conferred upon him in 1861. He became captain in the Algerian rifle corps, and joined the Mexican expedition. **III. Louis Lucien**, a philologist and chemist, second son of Lucien, born at Thorn Grove, Worcestershire, England, Jan. 4, 1813. In his early life he resided in the United States and in Italy, mainly devoting himself to philological and other scientific studies. After the revolution of February, 1848, he was chosen member for Corsica to the constituent assembly, but his election was annulled. In 1849, however, he was chosen by the department of the Seine to the legislative assembly; and in 1852 he was made senator, with the title of French prince and highness. His works on chemistry, and especially on philology, won for him a doctor's diploma from the university of Oxford, the membership of the academy of sciences of St. Petersburg, and other marks of distinction. He has published translations of St. Matthew's parable of the sower into 72 European dialects; *La langue basque et les langues finnoises* (London, 1862); a Basque version of Solomon's Song (1863); and numerous other writings relating to Basque, Celtic, and other branches of philology, besides several works in French and in Italian on chemistry. **IV. Pierre Napoléon**, third son of Lucien, popularly known as Prince Pierre, born in Rome, Sept. 12, 1815. He went in 1832 to the United States, served with Santander in South America, and was involved in quarrels owing to his violent temper. He then returned to Italy, where he soon made himself obnoxious, and in 1836 the papal authorities ordered him to depart. Of the policemen who came to escort him to the frontier he killed the chief and wounded two of the subordinates; but being himself wounded in the fray, he was obliged to surrender, and for a considerable

time was imprisoned in the castle of Sant' Angelo. On his release he returned to the United States, where he was soon again involved in troubles. He next went to England, and afterward to Corfu. After having in vain offered his military services to France and Egypt, he at length obtained in 1848 employment in the foreign legion of the French army. He was elected to the constituent and legislative assemblies, where he acted with the extreme left, vehemently opposing all reactionary measures. In 1849 he joined the army in Algeria, but returned to France without permission at the most critical moment of a siege. For this he was cashiered with the express approval of the assembly; and he fought a duel with a journalist who had commended his dismissal. After the *coup d'état* of Dec. 2, 1851, he kept aloof from politics, though invested with princely dignities and endowments, and lived at Auteuil, near Paris, with his mistress, the daughter of a washerwoman of the faubourg St. Antoine, whom he married in 1869. In 1870 he acquired great notoriety by his assassination, on Jan. 10, of one of Rochefort's collaborators, the journalist Victor Noir, who with his colleague Ulrich de Fonvielle called at his country residence to demand satisfaction from him in behalf of their friend Paschal Grousset, who charged the prince with having disparaged him in a newspaper published in Corsica. The prince, after a brief altercation, shot Noir dead, and also aimed the revolver, which he had carried loaded in his pocket, at Fonvielle, who escaped unhurt. This event created a great sensation, and threw additional odium upon the imperial dynasty at a time when its fortunes had already begun to decline. Pierre was arrested, and to prevent disturbances in Paris, a high court, the members of which were carefully selected by the authorities, was convened at Tours, and the trial (March 20-27) resulted in his acquittal of the charge of murder, the prince pretending that he had acted in self-defence, having been slapped in the face by Noir. He was, however, condemned to pay an indemnity of 25,000 francs to the family of his victim, and to bear the costs of the trial. The emperor requested him to leave the French territory, and he has since resided in London, mainly supported by his wife, who opened a fashionable millinery establishment there under her princely title. She has borne him several children, who were legitimized after their marriage. **V. Antoine**, the fourth son of Lucien, born at Frascati, Oct. 31, 1816. He was educated in Italy, and went in 1832 to the United States in the hope of meeting his father, who however had already sailed for England. Afterward he resided with him in Italy, but became involved in trouble with the papal troops and had to leave Rome. He returned there after the revolution of 1848, but refrained from joining the ultra democrats. In 1849 he went to France, and was a conservative member of the legislative assembly till Dec. 2, 1851, when he retired from politics.

As he did not court his cousin the emperor, he was excluded from the endowments enjoyed by many of his relatives who pursued a more obsequious course.

BONAPARTE, Napoleon, emperor of France, born in Ajaccio, Corsica, Aug. 15, 1769, two months after the conquest of the island by the French, died at St. Helena, May 5, 1821. It is related that, his mother being taken in labor suddenly as she was returning from mass, he was born on a piece of old tapestry, on which were figured the events of the Iliad. As a boy he manifested a violent and passionate temper, and in the little disputes with his elder brother Joseph he always came off master. The traditions report also that he delighted in running after the soldiers, who taught him military manœuvres; that his favorite plaything was a small brass cannon; and that he regularly drilled the children of Ajaccio in battles with stones and wooden sabres. His first teacher was his mother, who exerted a powerful influence upon his mind. He was next admitted to the royal college of Ajaccio, and spent a short time with his father on the continent, and with his brother Joseph at the college of Autun. In his 10th year, April 23, 1779, he was sent to the military school at Brienne, where Pichegru was one of his instructors. His companions there regarded him as taciturn and morose; but as he was a Corsican, speaking very little French, and poor as well as proud, like those islanders generally, his conduct is doubtless to be ascribed as much to his circumstances as to his temperament. Toward those who showed him sympathy, like Bourrienne, he was susceptible of strong attachments. The annual report of the school for 1784 says of him: "Distinguished in mathematical studies, tolerably versed in history and geography, much behind in Latin and belles-lettres, and other accomplishments; of regular habits, studious, and well behaved, and enjoying excellent health." His favorite author was Plutarch. The stories of his assuming undue authority over his fellows are contradicted by Bourrienne in his *Mémoires*. In 1784 Napoleon repaired to the military school at Paris to complete his studies. He was shocked at the expensive style of living there, and wrote a letter against it to his late superior at Brienne, Père Berton. In September, 1785, he was commissioned a sub-lieutenant of artillery, and soon afterward was promoted to be first lieutenant of artillery in the regiment of Grenoble, stationed at Valence. There he wrote an essay for the prize offered by the Lyons academy, on the question, "What are the principles and the institutions necessary to make man happy?" and was successful. Talleyrand, having procured this essay, showed it to Napoleon when he was at the height of his power, and he cast it into the fire. With his friend De Manis he also made an excursion during that time to Mont Cenis, which he purposed to describe in the style of Sterne's "Sentimental Journey,"

then much in vogue; but he did not complete what he had designed. A pretty Mlle. Calombier of Valence, with whom he had stolen interviews and "ate innocent cherries," was supposed to have inspired the sentimental part of this literary plan. A more suitable undertaking was the project of a history of Corsica, which he began, and communicated to Paoli, then living in exile in London. The parts of it still preserved are full of warm patriotic expressions and vehement democratic thoughts. They were not phrases borrowed from the classic authors, but the spontaneous outbursts of a fresh young mind, stimulated by the spirit of his age, and not yet contaminated by the experiences of life, or fettered by its own schemes of aggrandizement. Napoleon visited Ajaccio every year, and interested himself in furthering the education as well as the fortunes of his brothers and sisters. Though not the oldest son, he was instinctively recognized as the true head of the family, his father having died in 1785. His allowance in those days, probably furnished by his uncle, was 1,200 francs. Nothing could have been more decided than his democratic tendencies at this period. The great revolution of France was already moving powerfully onward, and he, in common with the other officers of the regiment at Valence, watched its complicated movements with deepening anxiety. Many of those officers openly took part with the royalists, while others, and among them Napoleon, inclined as strongly to the revolutionary side. On Feb. 6, 1792, he became a captain of artillery by seniority, and in the same year, being at Paris, he witnessed the insurrections of June 20 and of Aug. 10. Bourrienne relates that on the former of these occasions, when he saw the mob break into the palace, and force the king to appear at the window, with the *bonnet rouge* on his head, Bonaparte exclaimed: "It is all over with that poor man! A few discharges of grape would have sent those despicable wretches flying." Paoli, having emerged from his retirement, had been enthusiastically received at Paris, and invested with the presidency and military command of his native island, where the ferment of revolution was also at its height. Ajaccio appears to have been for a while the headquarters of the patriots, the Bonaparte house their place of meeting, and Joseph and Napoleon (who had returned hither) the acknowledged leaders. But Paoli's views of liberty were far more moderate than those of the national legislature, and in a little while he found himself in direct opposition to the government. The Bonapartes, strongly attached to him personally, did not follow him in this movement, as the inhabitants of Ajaccio did generally, but adhered to the cause of the convention. A civil war was the consequence of Paoli's defection; and in the course of it Napoleon, who acted provisionally as the commander of a battalion of the national guard, had the unpleasant duty laid upon him of assaulting his native place.

He succeeded against it at the outset; but the besieged party rallying, and his communication with the frigate which had set him ashore having been cut off, he was deprived of his temporary success, and in turn besieged in the tower of Capitello. During this time he and his 50 men were reduced to the extremity of living for three days upon horse flesh, when some shepherds from the mountains released them from their situation. The exasperation of the adverse faction now drove the Bonapartes out of Ajaccio. Madame Lætitia, frightened by the signs of imminent danger, fled with her children to Milelli, and thence across the rugged mountain roads to the seashore, where they concealed themselves in the thickets until Napoleon succeeded in conveying them to Nice, whence they removed to Marseilles (1793). During their residence at Marseilles Napoleon was employed by the general commanding the artillery of "the army of Italy" to negotiate with the insurgents of Marseilles and Avignon. In the latter place he published in the same year a little pamphlet called *Le souper de Beaucaire*, in which he endeavored to persuade the excited people of those parts not to provoke the vengeance of the revolutionists, who were then the ruling power, and who were dealing a fearful retribution upon all whom they suspected to be the enemies of the country. Its sentiments were generally republican, and in favor of the Montagne, as against the Girondists, but not at all Jacobinical, as has been alleged. The pamphlet is given in Bourrienne, and translated in the appendix to Sir Walter Scott's "Bonaparte." But the provinces were not the sphere for Napoleon, and he repaired to Paris, where he spent a part of the summer of 1793. In September he was ordered on service at the siege of Toulon, then possessed by the Spanish and English, where he displayed such extraordinary military intelligence and activity as to lay the foundation of his whole subsequent military career. After reconnoitring Toulon for a month, he communicated to the council of war a plan of attack, which was adopted, and which he himself executed with brilliant success. The place was so important that the capture of it diffused a general joy over France, and gave to the young colonel of artillery, by whom the reduction had been chiefly accomplished, a distinguished name. In consequence of his services, he was recommended by Gen. Dugommier for promotion, and on Feb. 6, 1794, was made a brigadier general of artillery. He was then in his 25th year. Dugommier's letter to the committee of public safety in regard to him said sagaciously enough: "Reward this young man and promote him; for, should he be ungratefully treated, he will promote himself." Joining the army under Gen. Dumerbion, stationed at the foot of the Maritime Alps, he made the campaign of 1794 against the Piedmontese troops. On the downfall of Robespierre, on the 9th Thermidor, 1794, he was sus-

pected by the moderate party of too strong a sympathy with that leader, and, in spite of his disclaimers, was temporarily put under arrest. He wrote a sharp remonstrance against this proceeding, and was released by the committee of public safety, after a detention of about a fortnight. At the close of the campaign of that year he went to Paris again to solicit some new employment, but, in spite of his abilities, he did not procure it instantly. His letters to his brother Joseph, written during this time, have the tone and manner of those of a mere adventurer, somewhat depressed by ennui, and waiting impatiently upon fortune, though ready for any good luck that may turn up. "Life," he remarks, "is a flimsy dream, soon to be over," as if he was yet unsuspecting of what a disturbed and restless dream his was destined to be. He lodged in the rue du Mail, near the place de la Victoire, often complained of his poverty and suggested schemes for raising money, and at one time thought of offering his services to the sultan of Turkey. But the constitution of the year III. organizing the directorial government having in the mean time been adopted (1795), and the Thermidoreans of the convention which adopted it having passed two decrees declaring that the two new councils created by the constitution should in the first instance be constituted of two thirds of the present and one third of new members, and ordering the electoral bodies to nominate the third that were to be returned, a new germ of civil war was planted. The sections or primary assemblies of Paris resisted this dictatorial attempt of the convention to perpetuate its own power, and the convention prepared to put down the sections. The convention held at its disposal some 5,000 regular troops, besides a large number of cannon, under the general control of Barras, one of its members. Menou was at first chosen to lead these troops against the people, but, through indecision or want of energy, failed in his movements. Barras, who had known Napoleon at Toulon, then said to the committee of the convention that the young Corsican, who was already employed by them in some slight military occupation, was the very person to take command. They accordingly gave it to him, and he, willing to fight for the people or against them, as best served his own designs or necessities, made his arrangements for the dispersion of the populace. On the morning of the 13th Vendémiaire (Oct. 5, 1795), the national guards, as the defenders of the sections were called, advanced, to the number of 30,000 men, along the quays of the Seine, the rue St. Honoré, and other approaches to the Tuileries. Everywhere as they advanced, however, they encountered a most formidable resistance. Napoleon, though he had but one night to make his arrangements, left no point undefended, while he established bodies of troops in the best positions, and to a fire of musketry returned a murderous discharge of cannon.

In less than an hour of actual fighting he secured the victory to the convention, and, Barras resigning, he became the commander-in-chief of the army of the interior. One of the letters addressed to Joseph by Napoleon during intervals of his idleness said, jokingly, "If I stay here it is possible I may be fool enough to marry," and fortune had already prepared his bride for him. Moving in the society of Barras, Tallien, Carnot, and their families, was a young widow named Josephine Beauharnais, a native of Martinique, and possessed of rare beauty and accomplishments. Bonaparte paid his addresses to her, and was soon an accepted lover. On Feb. 23, 1796, he was appointed, at the instance of Carnot, to the command of the army of Italy, which for three or four years had been carrying on an indecisive war against the Sardinians and Austrians, amid the defiles of the Alps and the Ligurian Apennines. His marriage took place the next month, March 9, and in less than a week afterward he departed to assume command. His army consisted of about 35,000 men, and was in a miserable state of destitution as to clothing and provisions, and considerably relaxed in discipline. The allied army opposed to him contained some 60,000 men, conducted by Beaulieu, an experienced and courageous general, and manœuvred according to the most skilful strategies of the time. But, in spite of the superiority of numbers and experience, Napoleon brought to the campaign several incontestable advantages: 1, the enthusiasm and alacrity of a young mind given for the first time a separate and independent field of glory, and determined on conquest or ruin; 2, an unrivalled power of combination, joined to a celerity of movement that seemed almost miraculous; and lastly, the free use of such a stimulant to the hopes of impatient and desperate troops, half famished amid the barren Alpine rocks, as the promise of an unrestrained enjoyment of "the rich provinces and opulent towns" of Italy. Against France, at that time, a formidable coalition, consisting of England, Austria, Bavaria, Piedmont, Naples, and several minor states both of Germany and Italy, was arrayed; but Austria was the principal of the league, and the possession of Italy the key to the situation. Napoleon perceived this, and at once proceeded to make himself master of Italy. On April 12 he gained a victory at Monte Notte; on the 14th, that of Millesimo; on the 15th, that of Dego; on the 21st, that of Mondovi; by which series of successes the king of Sardinia was compelled to sue for peace. Turning his attention next to upper Italy, he advanced upon Lodi, where he forced the passage of the Adda, May 10, in a brilliant battle which put Lombardy in his power. On May 15 he entered Milan, where heavy contributions were levied upon the state, and the principal works of art seized and sent to Paris. Naples, Modena, and Parma hastened to conclude a peace, and the pope was forced to sign an

armistice. Mantua was the next object of attack. Wurmser, at the head of large Austrian reinforcements, came through Tyrol to the defence; the two main divisions of his army were defeated at Lonato, Aug. 8, and at Castiglione delle Stiviere, Aug. 5, and driven back. On Sept. 4 another division of the Austrians was repulsed at Roveredo. Wurmser, having rallied his scattered troops in the mean time, was again attacked and routed at Bassano, Sept. 8. A third Austrian army, under Marshal Alvinczy, now entered Italy, and for a part of the autumn held the French in check; but on Nov. 15 a battle was joined at Arcole, which, after three days (15th-17th) of the hardest fighting that had yet occurred in the Italian campaign, gave the victory again to the French. Bonaparte then turned his attention to the settlement of the internal affairs of Italy, which was everywhere disturbed, and in many places in insurrection. A letter written to the directory, Dec. 28, 1796, reveals the principles upon which he acted in his various arrangements: "There are in Lombardy three parties: 1, that which is subservient to France and follows our directions; 2, that which aims at liberty and national government, and with some degree of impatience; and 3, that which is friendly to Austria and hostile to us. I support the first, restrain the second, and put down the third. As for the states south of the Po, there are also three parties: 1, the friends of the old government; 2, the partisans of a free aristocratical constitution; and 3, the partisans of pure democracy. I put down the first; I support the second, because it is the party of the great proprietors, and of the clergy, who exercise the greatest influence over the masses of the people, whom it is our interest to win over to us; and I restrain the third, which is composed chiefly of young men, of writers, and of people who, as in France and everywhere else, love liberty merely for the sake of revolution." In the beginning of the year 1797 Austria again took the field with a formidable army, which Napoleon encountered, Jan. 14, at Rivoli, and defeated. Immediately afterward Wurmser, who had stood an obstinate siege in Mantua, was compelled to surrender. On the same day, proclaiming that the truce with the pope was at an end, Napoleon entered the papal territories, and repulsed the papal troops on the Senio; took Faenza, and in quick succession Ancona, Loreto, and Tolentino; and on Feb. 19 forced the pope to conclude a peace. By this he was enabled to wage war upon Austria on her own soil. He crossed the Piave, and on March 16 forced the passage of the Tagliamento and the Isonzo; on the 19th he seized Gradisca, on the 20th Görz, and on the 23d Trieste. Before April 1 the greater part of Carinthia, Carniola, and Tyrol was reduced to subjection. On April 7 he granted the deputies of the archduke Charles an armistice of five days, and on the 18th of the same month concluded preliminaries of peace at Leoben,

which laid the Austrians under pretty severe conditions, and assured the French possession of Trieste, whence they proceeded to assail Venice. On May 3 a declaration of war against that republic was published, on the pretended ground of its having violated neutrality; and on May 12 the city was occupied, and a new constitution, somewhat less aristocratic than the old, was improvised. During the same month Genoa was revolutionized, and early in June received a new French constitution as the "Ligurian republic." On June 29, at Milan, the new Cisalpine republic was proclaimed, and speedily organized; and on July 14 the French army, retiring from the territories of the new republic, took up cantonments in the Venetian states. During the remainder of the summer and the autumn Napoleon was engaged in conferences and negotiations for a definitive treaty of peace with Austria, which was signed at Campo Formio, Oct. 17. By that celebrated arrangement Austria ceded her Lombard territories to the Cisalpine republic, and her former possessions in the Low Countries to France, guaranteeing the extension of its boundary to the left bank of the Rhine, while she received the Venetian provinces of Istria and Dalmatia, and the mainland of the republic as far as the Adige. Of the violence, the pillage, and the despotism which marked these Italian campaigns, it is for history to speak; but they did not prevent the popular French sentiment of the time from hailing Napoleon when he returned to Paris, Dec. 5, 1797, not merely as the conqueror, but as the liberator of Italy. In the short space of two years he had won a series of the most splendid victories on record, dictated forms of government to nearly the whole of Italy, humbled Austria, acquired large accessions of wealth and territory for France, and rendered the French arms formidable to the world. Under these circumstances, his journey from Italy to Paris was, of course, a triumphal procession; the enthusiasm of the Parisians was immense, and the festivals in his honor were endless; but Napoleon received his honors with becoming moderation, and was in fact sombre and thoughtful. Being a member of the institute, he assumed its dress, associated principally with men of science, and in all the congratulatory addresses of the period was extolled for his simplicity, his modesty, and his complete want of ambition.—The directory, then in power, had created an "army of England," with a view to hostilities against that country, and conferred the command of it on Bonaparte. He appeared to favor the movement, but at heart he disliked it, knowing how impracticable an attempt to conquer the island would prove; and he sought to substitute for it a magnificent dream of his own, the conquest of Egypt and the East. At last the directory consented to this, and Napoleon made his preparations to embark at Toulon. By May 9, 1798, a great army had been collected, and the expedition

set sail on the 19th. On June 10 it landed at Malta, and on the 12th took possession of the island, which was garrisoned by the French. A week later the fleet renewed its course, reaching Alexandria July 1. On the following day the French took the city, and having secured it advanced toward the Nile. They crossed the desert, and reached the river July 10. A flotilla ascended the stream, while the army marched along the shore. Arriving before Cairo July 21, they encountered a large body of Mamelukes under Murad Bey, which, after a most determined struggle, was repulsed. The battle was called the battle of the Pyramids, and the success of the French struck terror far into Africa and Asia. Many of the surrounding tribes submitted to the conqueror. But fortune was preparing for him a terrible reverse. His fleet, consisting of 13 ships of the line, besides frigates, was found in Aboukir bay by Nelson, the English admiral, who had long been in pursuit of it, and was attacked on the evening of Aug. 1, with a degree of vigor and activity which was never surpassed in naval warfare. The whole squadron, with the exception of two ships of the line and two frigates, was destroyed or captured. Bonaparte being cut off from the means of return, the sultan issued a declaration of war against him, Sept. 10, for invading one of his provinces, incited an insurrection in Cairo, and prepared to send an army into Egypt. In February, 1799, Bonaparte crossed the desert with about 13,000 men, took El-Arish and Gaza, stormed Jaffa, where 2,500 Turkish prisoners were deliberately massacred, and advanced into Syria. On March 17 the French army reached Acre, defended by a strong force of English, under Sir Sidney Smith, and two ships of the line. Repeated but ineffectual attempts to storm the place were made up to May 20, when Napoleon saw himself compelled to abandon the siege. The French army retreated to Cairo, which place they entered June 14. The Syrian campaign, which had lasted three months, cost the French 4,000 men, who were either killed or died of the plague. On July 25 they recovered the possession of Aboukir from the Turks, after which Napoleon, whom his brother Joseph had succeeded in informing of the distracted condition of France and the growing unpopularity of the directory, returned home privately with a few personal adherents. He endeavored to conceal the failure of his expedition under the glory of its immense scientific results, but he could not disguise from himself that his plan to molest the English supremacy in India, to colonize Egypt, to give France the command of the Mediterranean, and to build up for himself, perhaps, a vast oriental empire, had miscarried. He returned in time to take advantage of the political intrigues then rife, and, by the *coup d'état* of the 18th Brumaire (see BRUMAIRE), to attain supreme power as first consul of the republic (December, 1799). From this time his line of policy unfolded itself

more distinctly; to establish order at home, and to humiliate the enemies of the nation, were the honorable objects of it; but the extension of his own power was unfortunately an end scarcely less conspicuous. Nothing could have been more needed than a reformation of the administrative departments; the finances were deranged, the treasury empty, the taxes increasing, and trade at a standstill. In the same summary manner in which he ordered his troops, but with remarkable sagacity, and still more remarkable courage and activity, Bonaparte undertook to reform civil affairs. At the same time, Austria, England, and the Porte, if not carrying on active hostilities against France, refused all terms of peace, and a civil war was raging in La Vendée. Suppressing the latter by a series of decided but conciliatory measures, he turned his whole attention to the continental war. An army was secretly concentrated near the lake of Geneva, with which he passed the Great St. Bernard May 14-20, 1800, and entered Milan June 2. On the 14th of the same month, after several unimportant skirmishes, he met the Austrians under Gen. Melas at the village of Marengo, where he achieved another brilliant victory, and by this unexpected blow at once recovered the supremacy of France in Italy, which had been lost in his absence. Having established provisional governments at Milan, Turin, and Genoa, he returned to Paris, where he was received, July 3, with immense enthusiasm, but in December barely escaped assassination by an infernal machine. As his general, Moreau, had also defeated the archduke John in the great battle of Hohenlinden, Dec. 3, 1800, Austria was obliged to make a separate peace. The preliminary treaty of Lunéville, dated Feb. 9, 1801, made a new arrangement of the states of the continent; and although it was essentially the same as that of the treaty of Campo Formio, it contained provisions which laid the foundation of much subsequent trouble. Pursuant to the same objects, treaties were concluded with Spain, March 21, 1801; with Naples, March 18; with the pope, July 15; with Bavaria, Aug. 24; with Portugal, Sept. 29; with Russia, Oct. 8; with Turkey, the 9th; with Algiers, Dec. 27; and the treaty of Amiens with England, March 27, 1802. Thus it seemed as if a universal cessation of hostilities was about to mark the history of Europe. To the title of conqueror the first consul now added that of pacificator. But his attempt to crush an insurrection of the blacks in Santo Domingo, for which an expedition had been sent out toward the close of 1801, under his brother-in-law Gen. Leclerc, is not to be regarded as one of the grounds of this latter title. The greater part of the army, some 20,000 in number, was swept away by fever and the sword; the blacks were instigated by brutal cruelties to still more brutal massacres; and the island was desolated by the fiercest exhibitions of alternate terror and revenge. It was by the direct act of Napoleon

that slavery was reestablished in Guadeloupe, and the slave trade reopened. Toussaint Louverture, an able and courageous Haytian negro, who had made himself the leader of his struggling countrymen, was seized during a truce, and carried to France, where he died in prison. Napoleon availed himself of this interval to perfect the administration of the interior affairs of his country. A general amnesty allowed all the French emigrants to return home; a new order of knighthood known as the legion of honor was established, and the constitution of the Cisalpine republic was perfected. On Aug. 2, 1802, Bonaparte was proclaimed consul for life by a decree of the senate, which was confirmed by a popular sanction of some 3,000,000 votes. A *senatus consultum*, issued a few days after, reconstructing the electoral bodies and reducing the tribunate to 50 members, indicated, however, that he was not yet satisfied with the dignity to which he had been raised. Many persons saw in the movement a cautious step toward a still more absolute power.—It is to this period that the greatest of Napoleon's services to France belongs. The civil code, which has ever since been the law of the nation, was then digested and arranged by a commission of eminent lawyers and civilians, under the presidency of Cambacères. The various branches of public instruction also attracted his attention; and the lyceum, the college of France, the polytechnic and other military schools, were organized on the most liberal scale. But the perfection of the centralization begun by the revolutionary assemblies, which reduced the provincial administration of France to one uniform plan, having its head at Paris, and completely abrogating the old communal liberty and independence, was a more questionable reform. Nor were his efforts to restore the religious harmony of France, by renewing the ancient privileges of the Catholic priests, as happily conceived as many of his political improvements. In fact, like nearly all organizers and reformers, Napoleon undertook too much, and in the exaggeration of his own powers fell into many mistakes. Yet, in considering the epoch of the consulate, it is impossible not to derive from it a high admiration of the scope and versatility of Napoleon's genius, and a general sympathy with his public aims. But already his head was giddy with success, and in the midst of the great labors of 1802 he coveted the imperial diadem. Disturbances in Switzerland in the beginning of 1802 caused Napoleon to resort to an armed mediation in its affairs; in August of the same year the island of Elba was united to France; on Sept. 11 the incorporation of Piedmont took place, and in October that of the duchy of Parma. England professed to see in these events an infringement of the treaty of Amiens, and in a short time there was an open resumption of hostilities. On March 21, 1803, a *senatus consultum* placed 120,000 conscripts at Napoleon's com-

mand, while England made no less active preparations. On May 18 England declared war against France, and laid an embargo upon all French vessels in her ports. France retaliated by a decree that all Englishmen, of whatever condition, found on her territory, should be detained as prisoners of war; and Gen. Mortier was sent to occupy the electorate of Hanover, as belonging to Great Britain. In the mean time, the police of Paris professed to have discovered a conspiracy against the life of the first consul, in which Pichegru, returned from exile in Guiana, Georges Cadoudal, a Chouan chief, and Gen. Moreau were said to be concerned. These were arrested, and suspicions of complicity attaching to the duke d'Enghien, son of the duke de Bourbon and grandson of the prince de Condé, the neutral territory of the grand duchy of Baden was invaded in order to effect his seizure. He was taken during the night of March 15, 1804, conveyed to the citadel of Strasburg, and thence, under escort, to the castle of Vincennes. A military court, consisting of seven, was hastily summoned there by the first consul, by which the duke was tried and found guilty of the charges of bearing arms against France, of offering his services to England, of conspiring with emigrants on the frontiers, and being an accomplice of the Paris conspirators. He was sentenced to death, and executed the next morning, March 21, between 4 and 5 o'clock. On April 6 Pichegru was found dead in his prison. At a later period Georges Cadoudal and others were executed, while some of their confederates were reprieved, and Moreau was banished.—It was in the midst of these sinister events that a motion was made in the tribunate by one Curée that Napoleon be made emperor of the French, with the right of succession to his family. Carnot spoke against the motion with much patriotic fervor, but it was carried by a large majority. On submission of the question to the votes of the people, an apparent popular sanction was given to the deed, and on May 18 Napoleon assumed the imperial title. He requested the pope to perform the ceremony of his coronation. Pius VII., after consulting with his cardinals, came to Paris for that purpose in November. On Dec. 2 the "soldier of fortune," as he had been sometimes called, was consecrated at the altar of Notre Dame, "the high and mighty Napoleon I., emperor of the French." Being emperor, he proceeded to surround himself with all the splendors and gauds supposed to be essential to the dignity. He created a new nobility with sounding titles; he opened a brilliant court; he restored the etiquette of royalty, and in a thousand other ways sought to dazzle weak minds by ostentation and parade. The changes which had taken place in France rendered changes in the Italian governments necessary, and from republics they were transformed into a kingdom. Napoleon went to Milan, where on May 26, 1805, he was anointed

king of Italy, in the midst of imposing ceremonies and theatrical pomp. The same summer the northern powers listened to the solicitations of England, and united in a coalition against the new emperor. Russia, Austria, and Sweden joined in the charges of territorial usurpation which were levelled at Napoleon; but Prussia, already bribed by him with the promise of Hanover, could not be seduced into becoming a party. By September the French forces in eight divisions, and numbering 180,000 men, were upon the Rhine, ready to act against Austria. That country, governed by decrepit bureaucrats, sent forward its troops under an incompetent general, Mack, without waiting for the Russian allies. On Oct. 17, being completely surrounded by Napoleon at Ulm, he conditionally capitulated, and on the 20th he surrendered his whole army of 28,000 men. The next day, however, the great victory of Nelson at Trafalgar, over the combined fleets of France and Spain, compensated the allies for this reverse. Nothing daunted by the naval disaster, Napoleon advanced to Vienna, which city he entered Nov. 18, where he made his preparations to meet the combined armies of Russia and Austria, then concentrating on the plains of Olmütz. On Dec. 2, 1805, the grand encounter came on at Austerlitz, and after a struggle of unexampled energy—in which three of the greatest armies of Europe, each commanded by an emperor, with the mastery of the continent for the prize, met in desperate strife—Napoleon won the victory, the most glorious perhaps of his career. The allies were thoroughly routed; the emperor of Austria made instant peace, while the emperor of Russia withdrew into his own territories. The king of Prussia was rewarded for his neutrality by the possession of Hanover, and England alone remained to stem the tide of success which was bearing forward the victorious Corsican. As the king of Naples, instigated by his wife, an Austrian princess, had received the troops of Russia and England into his dominions during the recent war, Napoleon construed the act into one of predetermined hostility, and in February, 1806, sent an army under his brother Joseph to occupy the country. The king fled to Sicily, when Napoleon declared the crown vacant, and conferred the title of king of Naples and Sicily upon Joseph, March 30. Following this by another decree, he transformed the Batavian republic into a kingdom, dependent upon France, and gave the crown to his brother Louis, June 5. About the same time he erected various districts in Germany and Italy into dukedoms, which he bestowed upon his principal marshals. But a more important act was that of July 12, which created the confederation of the Rhine, and which some 14 princes of Germany were induced to join, thereby placing themselves under the supremacy of France, and detaching some 16,000,000 people from the tottering German empire. The policy which Napoleon had pur-

sued in making two of his brothers kings, he now extended to his sisters and brothers-in-law, who were distributed as rulers over various countries of the continent. William Pitt, the minister of Great Britain, having died Jan. 28, 1806, and Charles Fox succeeding to his place, negotiations were opened between France and England in regard to the termination of hostilities. In the course of these, propositions were entertained looking toward a restoration of Hanover to the latter power, which at once opened the eyes and aroused the jealousies of Prussia. It was not long before the Prussian monarch acceded to the coalition against Napoleon, and entered into active preparations for war. The emperor, whose celerity of action was prodigious, instantaneously moved toward Prussia with a powerful force, and by Oct. 8, 1806, had reached the Prussian outposts. On the 14th he routed the enemy with fearful slaughter at Jena, and the same day Marshal Davoust achieved most important successes at Auerstädt, the duke of Brunswick being among the killed. By this double encounter, in which more than 20,000 Prussians were killed, the strength of the kingdom was fatally broken, and Napoleon followed up his victories with such signal energy that, in two weeks from the commencement of hostilities, Oct. 27, he entered the Prussian capital in triumph. After occupying almost all the fortresses, and reducing such towns as still maintained a show of resistance, he issued from Berlin, Nov. 21, the famous decree, declaring the British islands in a state of blockade, forbidding all correspondence or trade with England, defining all articles of British manufacture or produce as contraband, and the property of all British subjects as lawful prize of war. Meanwhile the Russian allies, who had advanced as far as the Vistula, were driven back through Poland, and the French entered Warsaw. A winter campaign was then begun against the Russians; but after the indecisive battle at Pultusk, Dec. 26, the Russians retreated to Ostrolenka, and the French behind the Vistula, toward the north. The month of January, 1807, was spent in repose and preparation by both sides, and on Feb. 7 and 8 a desperate engagement took place at Eylau, in which a loss of 50,000 men was divided between them, and both claimed the victory. The following May Napoleon attacked and conquered the important fortress of Dantzic, and having reinforced his army with 200,000 men, he once more advanced against the Russians. On June 14 the battle of Friedland was fought, and the Russians were so worsted that Alexander asked for an armistice. The two emperors met for the first time, June 25, on a raft in the middle of the Niemen, and on July 7 a treaty of peace was concluded at Tilsit. The Prussian monarch received back about half his dominions; the duchy of Warsaw was created and given to the elector of Saxony, an ally of the

French, who was made a king; while the principal Prussian fortresses and seaport towns remained in the possession of the French till a more general peace should be concluded. Russia obtained a part of Prussian Poland, and by secret articles was allowed to take Finland from Sweden. Out of the Prussian territory on the left bank of the Elbe, Hesse-Cassel, Hanover, and Brunswick, the new kingdom of Westphalia was formed, and bestowed upon Jerome. Soon after the treaty of Tilsit, England, conceiving that Napoleon, with the connivance of Russia, was about to make arrangements with Denmark and Portugal for the conversion of their fleets to his purposes, which would expose her to the assaults of the combined navies of Europe, sent a powerful squadron to bombard Copenhagen. Denmark, upon the surrender of that place, threw herself openly into the hands of France. As to Portugal, however, which had refused to enforce the Berlin decrees against England, and despatched her fleet to Brazil, at the instigation of England, to avoid lending aid to France, Napoleon declared that the house of Braganza had ceased to reign, and sent Junot to occupy Lisbon. On Nov. 27, 1807, the prince regent, the queen, and the court of Portugal embarked for a foreign port, and on the 30th the French entered their capital. In December of the same year Napoleon became involved in a serious controversy with the pope, which led to the annexation of the Adriatic provinces to his kingdom of Italy, and to the military occupation of Rome. At the same time Napoleon found a pretence for interfering in the affairs of Spain. A series of corrupt intrigues, in which the king, Charles IV., his queen, the favorite Godoy, and the pretender to the throne, Ferdinand, son of Charles, were engaged, had involved the internal administration of Spain in inextricable confusion. Napoleon cut the Gordian knot with his sword. Madrid was occupied by Murat, March 23, 1808; Charles and Ferdinand were both induced by Napoleon to abdicate at Bayonne, and he made Joseph king of Spain, transferring the kingdom of Naples to Murat. Many of the Spanish nobility acquiesced, but the great body of the people rose in arms against the French. Ferdinand, although a prisoner in France, was declared by them the legitimate monarch, while England sent immense supplies to sustain the insurrection, and Napoleon prepared to enforce his policy. A war which lasted nearly six years was thus begun in the peninsula. At the outset the Spaniards were successful. On June 14 a French squadron was captured by the English fleet in the bay of Cadiz; on the 28th Marshal Moncey was repulsed in an attack upon Valencia; for two months Palafox made a heroic defence of Saragossa; on July 20 the new king made his triumphal entry into Madrid; on the 22d Gen. Dupont, with 18,000 men, surrendered to the Spaniards at Baylen; and a week

later Joseph, with all his remaining forces, commenced a retreat beyond the Ebro. On Aug. 21 Marshal Junot was defeated at Vimeira by Sir Arthur Wellesley, and this battle led to the convention of Cintra, under which Portugal was evacuated by the French forces. Napoleon therefore deemed it necessary to take the field in person, and in the early part of November appeared in the north of Spain with 180,000 men. The Spaniards were rapidly defeated at Reynosa, Burgos, and Tudela, and on Dec. 4 he entered Madrid. The British troops, hastening to the assistance of the Spaniards, were pursued to and ineffectually attacked at Corunna, but their leader, the gallant Sir John Moore, was fatally wounded. The presence of Napoleon seemed to have redeemed nearly every reverse. But in January, 1809, he was compelled to return to Paris to counteract the movements of Austria, which, taking advantage of the peninsular war, had sent forward large bodies of troops into Tyrol and Italy. On April 17 he assumed the command of his army, and before the close of the 22d he had completely routed the Austrian forces. On that day, at Eckmühl, he defeated the archduke Charles; on May 13 he again entered Vienna; on the 21st and 22d he was worsted at Aspern and Essling, but on July 6 he more than recovered all his losses, gaining a stupendous victory at Wagram, which enabled him to dictate once more his own terms of peace. During these troubles the Tyrolese seized the opportunity to raise the standard of insurrection; the British made a descent upon the coast of Holland; Sir Arthur Wellesley was carrying on a most effective war in Spain, and the difficulties with the pope were renewed; yet Napoleon contrived to make face against all these assaults. By a decree of May 17 the Papal States were annexed to the French empire, which was followed by a bull of excommunication against Napoleon, when the pope himself was arrested and conveyed to Paris, where he remained a virtual prisoner till 1814. In the midst of his triumphs an attempt upon Napoleon's life was made, Oct. 18, by a young German named Staps, from which he had a narrow escape. To crown the events of the year, it was announced in December that Napoleon was about to repudiate his wife Josephine, by whom he had no issue, in order to contract an alliance with some of the dynastic families, and thus procure to himself a successor of royal blood. On the 16th of that month an act formally divorcing him was passed by the obedient commissioners of the senate; and on April 2, 1810, he was married to the archduchess Maria Louisa, a daughter of the emperor of Austria. Josephine retired with a broken heart to Malmaison, and the new empress took the place of the affectionate and devoted companion of his early years. From this union there was born a son on March 20, 1811, who was proclaimed in his cradle king of Rome. The French empire had now reached

its greatest extent and its highest glory. In addition to the original 86 departments of France (including Corsica), it embraced three departments along the Alps, 15 W. of the Rhine, 15 beyond the Alps in upper and central Italy, and 7 Illyrian provinces, besides exercising control in Holland, in Spain, in the Italian kingdoms, in Switzerland, and in the confederation of the Rhine. The French code and French ideas were predominant at Warsaw, at Milan, at Naples, in Holland, Westphalia, and Bavaria. To Sweden a king was given in the person of Bernadotte. Holland, after having had his brother Louis as king, was annexed to France by decree of the senate, July 9, 1810. But in the Spanish peninsula the progress of the French was slow. Sir Arthur Wellesley, who had recently been made Viscount Wellington, exhibited a degree of military skill and activity which easily held the marshals of Napoleon in check, and called for the presence of the grand master of war himself. On July 10, 1810, the fortress of Ciudad Rodrigo capitulated to Ney, but on Sept. 27 Masséna was defeated by Wellington at the heights of Busaco, and on Nov. 14 driven from before the fortified lines of Torres Vedras. Early in 1811 Soult besieged Badajoz, and captured it on March 11, but on May 16 he was routed at Albuera. Thus a series of alternate successes and reverses marked the campaign throughout the year. The surrender of Valencia to Suchet, Jan. 9, 1812, was, however, the last of the French triumphs. Ten days afterward Wellington recaptured Ciudad Rodrigo; April 6, he recaptured Badajoz; July 22, he worsted Marmont at Salamanca; and 20 days later the capital of Spain was in the possession of the victorious English captain. But not until the battle of Vitoria, June 21, 1813, were the French driven entirely beyond the Pyrenees. Napoleon was personally occupied at the time with a greater enterprise than that of the reduction of Spain. His good understanding with Alexander of Russia had come to an end. The czar complained of his encroachments upon the interests of Russia, especially upon her commerce in the northern seas, and the commencement of the year 1812 saw both emperors engaged in formidable preparations for war. The scheme of a universal monarchy, which dazzled the ambition of Napoleon, seems to have blinded him to the consequences of his acts, or to have allured him to conquest with utter indifference to other results. A "grand army" of more than 500,000 men was gathered on the frontiers of Poland to enter upon the Russian campaign—one of the most stupendous as it was one of the most disastrous events in the records of history. Three hundred thousand Russians assembled on the banks of the Niemen to oppose the mighty force of the French. On June 24, 1812, Napoleon crossed the river, and the Russians retired step by step before the invaders. Tempests, rains, and famine

scoured the camps of the French, and yet they pushed forward. Under the walls of Smolensk, on the evening of Aug. 16, a division of the Russians ventured to make a stand against an advanced division of the French, and before the morning of the 18th the entire city was a heap of smoking ruins. Both the main armies drove rapidly on toward the city of Moscow. On Sept. 6, at the small village of Borodino, they halted, and came face to face with each other, resolved to risk a trial of strength. As the morning of the 7th dawned, a solitary gun announced the beginning of the fight; immediately 1,000 cannon belched forth their fire of death; more than 250,000 men were enveloped in the dense smoke of the conflict; and when the night fell more than 80,000 killed and wounded heaped the field. On the following day the Russians retired into Moscow, only to prepare the inhabitants to withdraw in a body before the irresistible arms of France. On the 15th, when Napoleon rode into the ancient capital, it was as silent as the desert, and he took up his residence in the Kremlin. But suddenly, at midnight, the city burst into flames in every direction, and the baffled French, enveloped in fire, were compelled to seek refuge in the desolate surrounding country. Napoleon lingered over the splendid ruins till Oct. 19, when, all his proposals for a peaceful adjustment of difficulties being rejected, he was reluctantly compelled to order a retreat. At first the weather was fine, and only moderately cold; but soon the snow, the rain, fatigue, and swarms of harassing Cossacks threw the dispirited Frenchmen into disorder. Then commenced that terrible retreat of 120,000 men, which for various suffering and horror has no parallel in the annals of our race. Napoleon himself returned immediately to France, and was almost the first to announce his disaster in his own capital, so rapidly had he fled from the scene. The loss of the French and their auxiliaries in this campaign was 125,000 slain, 132,000 dead of fatigue, hunger, disease, and cold, and 193,000 made prisoners; yet the emperor had scarcely reached Paris when he issued orders for new conscriptions, and still thought of prosecuting the war. This dreadful reverse encouraged the European powers to a sixth coalition, composed of Russia, England, Sweden, Prussia, and Spain, which early in the year 1813 sent forward its forces toward the Elbe, with a view to hem in the indomitable general, who seemed to set every misfortune at defiance. With an army of 350,000 men, in great part young troops, Napoleon repaired to Germany, where he won the battle of Lützen on May 2, and the battle of Bautzen on the 20th and 21st, but neither with decisive results. On June 4 an armistice was agreed upon, when Napoleon repaired to Dresden, where Metternich on the part of Austria offered a mediation with a view to closing the war. But Napoleon would not agree to the terms which were proposed to

him, fixing the limit of the French empire at the Rhine, and hostilities recommenced. From Aug. 24 to 27 a battle raged around the city of Dresden, with the preponderance of success on the side of the French; but, owing to the want of cavalry, Napoleon was unable to derive from it all the advantages for which he looked. The greater part of the month of September was passed in a desultory warfare, the French armies on the whole losing ground, and experiencing constant desertions on the part of their German allies. It was no longer merely the governments who were opposing Napoleon, but the people; and the prestige of popular sympathy, which had carried him along, even in the midst of nominal enemies, was beginning to fail. To the German masses the war had become a war of independence. (For a more detailed history of the great campaigns of 1813-'14, see BLÜCHER.) On Oct. 16 the battle opened at Leipsic, and a gallant struggle on the part of the French showed that their energies were still fresh, and the genius of their leader unimpaired. The 17th was a day of anxious suspense and rapid preparation. On the 18th the carnage was renewed, and Napoleon discovered that it would be necessary to retire beyond the Rhine. The morning of the 19th saw the dejected lines of the French slowly filing out of the city, when the allies forced their way into it, and by blowing up a bridge committed a sad havoc, and made some 25,000 prisoners. Thus, after an obstinate resistance of three days, Napoleon was compelled to retreat—a movement for which, prodigious as his genius was in assault and defence, he seemed to have but little capacity. As at Moscow, and later at Waterloo, his backward march was worse than a battle lost. Though he cut his way bravely through the Bavarians, his late friends, at Hanau (Oct. 30), yet when he crossed the Rhine but 80,000 remained of all his splendid army. He reached Paris Nov. 9, to encounter a strong feeling of dissatisfaction on the part of his own countrymen. The legislative body expressed a desire for peace, and could only be answered by a guard of soldiers. Yet, with a fertility of resource and a genius for combination which were almost miraculous, Napoleon was prepared by the end of January, 1814, to enter upon another campaign, which is called the campaign of France. Prussia, Russia, and Austria were already on her eastern borders; Wellington had crossed the Pyrenees, and had laid siege to Bayonne; Bernadotte, crown prince of Sweden and late companion of the emperor, was coming down from the north at the head of 100,000 troops; and Murat, king of Naples, Napoleon's own brother-in-law, had entered into a secret treaty with Austria for the expulsion of the French from Italy. Thus surrounded on all sides by enemies, with his disposable force shattered and broken, the indomitable emperor still repulsed their attacks, and still continued to astonish Europe with dazzling achievements. But numbers as

well as moral power were now against him; the allies succeeded in reaching the exterior defences of Paris; the capital, which for so many years had dictated law to all other capitals, was obliged to capitulate; and on March 31 Alexander and his allies entered Paris amid the acclamations of the people. The senate, formerly his too servicable instrument, declared that "by arbitrary acts and violations of the constitution," Napoleon had forfeited the throne, and absolved all Frenchmen from their allegiance. His own generals insisted that he ought to abdicate, and on April 11 he signed his surrender of power. He was allowed the sovereignty of the island of Elba, with a revenue of 6,000,000 francs; and after taking leave of his army at Fontainebleau, he departed for his new abode. On May 4 he landed from the British frigate *Undaunted*, at Porto Ferrajo; and Louis XVIII. resumed the seat of his ancestors.—Ten months later, invited by a conspiracy of old republicans, joined to the Bonapartists, Napoleon, who had not ceased to watch and foment the intrigues of Paris, was secretly returning to France. Escaping from Elba, Feb. 26, 1815, he landed at Cannes, not far from Fréjus, March 1, with an escort composed of about 1,000 of his old guard. As soon as his arrival was known, parts of the army, sent against him under Colonel Labédoyère and Marshal Ney, joined his cause; and he made a triumphal progress toward Paris. Europe was overwhelmed with surprise at the suddenness of the apparition. On March 20, and before a shot was fired, Louis XVIII. was driven from the throne to which he had just been restored by the combined armies of the world. The congress of Vienna, still in session, heard the news with astonishment, and instantly concerted a plan for conjoint resistance. The armies resumed their march toward the French frontier. Napoleon, hastily reorganizing the government, but on a basis more liberal than that of the empire, and having in vain attempted to open negotiations for peace, advanced to the encounter. Drained as France was by a long series of desolating conquests, upward of 200,000 men went forward to meet more than double that number of enemies. On June 15 Napoleon had crossed the Belgian frontier with 124,000 men; the next day he defeated the Prussians under Blücher, at Ligny; and at the same time he sent Ney against the English army at Quatre-Bras, where he was checked by Wellington. On the morning of the 17th the latter fell back upon Waterloo, and on the 18th the final battle was fought. (See WATERLOO.) The French were thoroughly dispersed, and the great captain hurried back to Paris. Once more the capital was occupied by foreign troops, and now also stripped of the treasures of foreign art with which the conqueror had adorned it; a war which had lasted for 23 years was closed; the legislature demanded a second abdication; on June 22, just 100 days after his resumption of power, the second abdication was signed; and Napoleon was required to em-

bark instantly for the United States. But Napoleon, arriving at Rochefort with a view to fly, found that there would be little probability of escaping the vigilance of the British cruisers, and voluntarily surrendered himself to Capt. Maitland, of the British war ship *Bellerophon*. The British government ordered his detention as a prisoner, and finally consigned him to the island of St. Helena for life. He landed at his place of imprisonment Oct., 16, 1815, and remained there, alternately fretting at the restraints imposed upon him and dictating memoirs of his extraordinary career, till May 5, 1821, when he died of an ulcer of the stomach, the same disease which had carried off his father. On the 8th of May his remains were interred beneath some weeping willows, near a fountain in Slane's valley; but 20 years afterward the king of the French, Louis Philippe, procured the removal of his ashes to France, where they were deposited Dec. 15, 1840, beneath a magnificent monument, in the *Hôtel des Invalides*. — Napoleon's marvellous character and career have occupied numberless pens, and the most divergent judgments have been passed upon them; but he has almost universally been accorded the possession of unsurpassed military ability, of indomitable self-reliance, of prodigious energy, and of a lofty and commanding intellect. The bibliography of Napoleon forms a literature, and we can therefore refer only to a few of the leading works in French and English. The *Mémoires* by Bourrienne, the *Souvenirs historiques* by the duchess d'Abrantès, the *Mémorial de Sainte-Hélène* by Las Cases, and the "Voice from St. Helena" by Barry O'Meara, are widely known, as are also the biographies of Napoleon by Sir Walter Scott, Lockhart, and Hazlitt. Besides these we must mention the various complete and selected editions of *Œuvres de Napoléon*; *Recueil par ordre chronologique de ses lettres, proclamations, &c.* (2 vols., Paris, 1855); *Le consulat et l'empire* by Thiers (20 vols.), and *Le consulat et l'empire, ou Histoire de France et de Napoléon Bonaparte*, by Thibaudeau (10 vols.); the works of Montholon and Gourgaud, under Napoleon's dictation (respectively 4 vols. and 2 vols.); *Vie politique et militaire de Napoléon*, by Jomini (4 vols.); *Documents particuliers sur Napoléon: Cours diplomatique et politique, extrait du Moniteur* (7 vols.); *Mémoires pour servir à l'histoire*, by Savary (4 vols.); *Précis des événements militaires*, by Mathieu Dumas (19 vols.); "History of the Captivity of Napoleon at St. Helena, from the Letters and Journals of the late Lieut. Gen. Sir Hudson Lowe" (8 vols.). Among valuable later histories of Napoleon are those by Elias Regnault (4 vols., 1846), by M. de Norvins (4 vols., 21st ed., 1851), by Bégin (5 vols., 1853-'4), by Baron Martin (de Gray), (8 vols., 2d enlarged ed., 1858), and by Pierre Lanfrey (Paris, 1867 et seq.; English, London, 1871). See further, *Correspondance de Napoléon 1^{er}* (32 vols., 1858-'69, the latter part edited under Prince Napoleon's di-

rection as president of the committee of publication; abstract in German by Kurz, 3 vols., 1868-'70). — **Josephine** (MARIE JOSEPH ROSE TASCHER DE LA PAGERIE), first wife of the preceding, born at Trois-Îlets, Martinique, in June, 1763, died at Malmaison, near Paris, May 29, 1814. Her father derived his surname Pagerie from a family estate near Blois, whence he had emigrated to Martinique, to serve as a naval officer under the marquis de Beauharnais, then in command of that island. Her mother, Rose Claire des Verges de Sannois, belonged to a family which had likewise settled in the colonies. In December, 1779, she was married at Noisy-le-Grand, France, to the viscount de Beauharnais, then about 18 years of age. She went with her husband to Paris, where in the house of her mother-in-law, Mme. Fanny de Beauharnais, she became acquainted with literary society. Her grace and loveliness were admired, but the education which she had received at the convent of Port-Royal, adequate for colonial life, did not fit her for the society in which the viscount moved. The unhappiness arising from this cause was soon aggravated by the husband's gallantries and the wife's complaints. Beauharnais finally brought suit for divorce in 1785. After a trial lasting nearly a year the court exonerated Josephine from all charges, authorized a separation, and ordered the husband to provide for her support and that of her daughter, but awarded him the custody of the son. The whole Beauharnais family siding with Josephine, she took up her residence with her father-in-law, and in June, 1788, she visited her parents in Martinique. On her return to Paris in the autumn of 1790 she became reconciled with her husband, and after his imprisonment she was arrested herself while attempting to release him, and narrowly escaped sharing his death by the guillotine (1794). Mme. de Fontenay, afterward Mme. Tallien, one of her fellow prisoners, on recovering her liberty, procured the liberation of Josephine, and afterward the restoration to her of a portion of her husband's confiscated estates. Among the many stories of the origin of her acquaintance with Bonaparte, that relating to the application of her son Eugène for his father's sword, and Josephine's visit to thank him for his kindness to her son, is regarded as the most authentic. At this time she had removed from the rue de l'Université to a house in the rue Chantierine which she had purchased from Talma, and here she received many visitors, Bonaparte habitually spending his evenings in her society. She was married to him March 9, 1796, and in less than a fortnight afterward her husband went to the seat of war in Italy. She joined him at his request, but was appalled at the sight of the battlefield, and soon returned. Bonaparte continued in the midst of his arduous labors to address to her tender epistles, and to complain of her lukewarm return of his love. She was with him at

Montebello and Udine in 1797, and in the latter part of that year she resumed her receptions at Paris, and was now a recognized leader of society. She wished to follow him to Egypt, but he insisted on her going to Plombières for her health. During his absence he was prejudiced against her by his sisters and other relatives, and on his return to Paris overwhelmed her with reproaches; but she soon appeased him, and after this the smoothness of their intercourse remained unruffled. In the first years of the consulate Josephine was at the zenith of her career. Her receptions at the Tuileries and Malmaison acquired great celebrity, and by her invariable goodness she won the hearts even of opponents. Yet she felt oppressed by the paraphernalia of court life, and it was at Malmaison only, with its magnificent pleasure grounds and embellishments of her creation, that she found relief from the burdens of etiquette. These became still more distasteful after her accession as empress (May 18, 1804). Napoleon's sisters attempted to exclude her from the coronation, mainly on the ground of her not having borne children to her husband. Nevertheless, she was crowned together with him as empress of the French (Dec. 2), but not afterward as queen of Italy. Previous to the coronation, the religious ceremony of marriage, which had not been observed at the time of their union, was celebrated. She now saw much less of her husband than formerly, and his increasing neglect filled her with sad forebodings, which were fully confirmed after the battle of Wagram in 1809, when he decided upon a divorce. He had first intended to prepare her for this through the medium of her son Eugène, but on her indulging in bitter recriminations he broke it to her abruptly. The ceremony preceding the divorce took place on Dec. 15. Overcome by her emotion, she could not continue to read aloud the declaration of her assent, which had been drawn up for her, and was taken home almost lifeless. She was to remain in possession of her imperial rank and titles, and to receive an annuity of 2,000,000 francs. The emperor visited her repeatedly, and enabled her to keep up the semblance of a court at Malmaison, and after the capture of Paris she declared her willingness to join him at Elba, but was restrained by the fear of hurting the feelings of Maria Louisa. The czar Alexander offered his protection to her, and the king of Prussia and his son dined with her at Malmaison. She died of quinsy, and was buried in the church of Rueil, in a tomb of marble erected by Eugène and Hortense. Her first valet de chambre, Constant, described her as a lady of middle size, exquisitely shaped, and with an elasticity of motion which gave her an aerial appearance. She had magnificent hair and eyebrows and dark blue eyes, and her expression was full of sentiment and kindness. The fortune-teller Mlle. Lenormand published memoirs of her, which are regarded as utterly

worthless, and the *Histoire secrète* by Lewis Goldsmith is deemed to be equally untrustworthy. The statement in the *Mémorial de Sainte-Hélène* that she wished to impose upon the nation a supposititious child she indignantly denied, maintaining that on the contrary this subterfuge was constantly pressed upon her by others. The *Histoire de l'impératrice Joséphine*, by Joseph Aubenas (2 vols., Paris, 1857-'9), from authentic sources, throws a purer light upon her character. The *Lettres de Napoléon à Joséphine, et de Joséphine à Napoléon, et de la même à sa fille* (Paris, 1838), are also regarded as good authority; but the correspondence and memoirs published in 1819 have been denounced as apocryphal. —**Maria Louisa**, second wife of Napoleon I., born in Vienna, Dec. 12, 1791, died there, Dec. 18, 1847. She was the eldest daughter of the emperor Francis I. of Austria, by his second wife Maria Theresa, whose father was Ferdinand IV. king of the Two Sicilies. Having been taught, like all her relatives, to execrate the name of Napoleon, she was at first appalled at the idea of marrying him; but resigning herself to her fate, she left Vienna on March 13, 1810. She met Napoleon near Soissons March 28. The civil marriage took place at St. Cloud, April 1, and the religious ceremony was performed next day at the Louvre by Cardinal Fesch. Most of the cardinals declining to attend, as the pope had not ratified the divorce from Josephine, they were banished from the capital and forbidden to wear their scarlet gowns, and hence they were called the black cardinals. Among the brilliant festivities of the marriage was a grand ball at the Austrian embassy, in the midst of which the building took fire and the empress was borne from the flames in the arms of Napoleon. She seemed at first to respond to her husband's warm affection, but she could not adapt herself to the society of the Tuileries, and her apathy and diffidence formed a striking contrast to her predecessor's vivacity. Her husband became still more attentive to her after the birth of a son in March, 1811. But she was as undemonstrative in her maternal as in all her other affections. She accompanied Napoleon to Dresden in May, 1812, where all the German princes paid homage to her. During the emperor's absence he appointed her regent, with a board to the decision of which she left the direction of public affairs. The emperor having ordered her to leave Paris on the entrance of the allies, she did not venture to disobey him, though urged by several of his relatives to remain at her post. She placed herself with her son under the protection of her father, and was easily persuaded to refrain from joining her husband at Elba. She never saw him again, and evinced no interest in his fate. The allies allowed her to retain for life the title of imperial majesty, and the congress of Vienna made her duchess of Parma, Piacenza, and Guastalla. After Napoleon's death in

1821, she contracted a morganatic marriage with Count Albert Adam von Neipperg, an Austrian general, then in his 47th year, who had been her chamberlain in 1815, and her reputed lover. He was divorced from his first Italian wife, by whom he had a son, who married Princess Mary of Württemberg. Maria Louisa bore him several children, and made him prime minister of Parma. He died April 22, 1829. During the disturbances in 1831 she was absent from her capital until order was restored by the Austrians; and shortly after the accession of Pius IX. in 1846, when a strong revolutionary excitement again pervaded Italy, she took her final departure from Parma. She was highly educated and attractive in person, her beauty being of the blonde Tyrolese style; but Lamartine properly characterizes her as a commonplace and motherly woman, fitted rather to shine in private life than to be associated with memorable events. Her fidelity was never suspected by Napoleon, who to the last regarded her as an incarnation of virtue and simplicity. See *Napoléon et Marie Louise, souvenirs historiques*, by Méneval; *Mémoires anecdotiques*, &c., by Bausset; and *Mémorial de Sainte-Hélène*, by Las Cases.—**NAPOLEON II.** (NAPOLÉON FRANÇOIS CHARLES JOSEPH, duke of Reichstadt), son of Napoleon I. and Maria Louisa, born in Paris, March 20, 1811, died in Schönbrunn, July 22, 1832. He was baptized at Notre Dame by his grand-uncle Cardinal Fesch. The archduke Ferdinand represented the emperor of Austria as godfather, and his godmother was Madame Lætitia. His father bestowed upon him the title of king of Rome, and on his abdication designated him as his successor to the imperial throne as Napoleon II., and he was recognized as such by the executive committee appointed by the chambers previous to the final accession of Louis XVIII. in 1815. The countess Montesquieu, the governess of the young prince, accompanied him to Austria, where his education was perfected under the direction of Count Maurice Dietrichstein. The right of succession to his mother's dominions in Parma being withdrawn from him in 1817, the emperor of Austria conferred on him in July, 1818, the rank of an Austrian prince with the title of duke of Reichstadt, and provided him with eminent teachers, Metternich being charged with the superintendence of his studies. The feeble efforts made after the revolution of 1830 in his favor were altogether unavailing, but the prince became more and more interested in the history of his father's military career, and Marmont, whom he met at the English ambassador's house in Vienna, gave him for three months a course of instruction on the Napoleonic campaigns. His military training having been the object of special care, he rapidly passed through various promotions, and in 1831 he commanded as lieutenant colonel one of the Hungarian infantry regiments of Vienna. He died of laryngeal phthisis, in the same room in

which his father had dictated peace to Austria, and was buried in Vienna in the vaults of the Austrian imperial family, in the church of St. Augustine. His eyes, remarkable for depth and brilliancy, reminded one of those of his father, and in his placid and amiable disposition he resembled his mother. On the establishment of the second empire in 1852, he became known as Napoleon II. in the order of imperial succession. His biographers are De Montbel (Paris, 1832-'3), Lecomte (de la Marne, 1842), Guy (de l'Hérault), and J. de Saint-Félix (1856).

BONAPARTE, Napoleon III. (CHARLES LOUIS NAPOLÉON, popularly known as LOUIS NAPOLEON), born in Paris, April 20, 1808, died at Chiselhurst, England, Jan. 9, 1873. His mother, Hortense de Beauharnais, had for some time lived apart from her husband, King Louis of Holland, and his paternity was questioned. It has been ascribed to the Dutch admiral Verhuel, and King Louis himself only reluctantly acknowledged the new-born as his son at the imperative request of Napoleon I., who stood as godfather, and Maria Louisa as godmother, at the baptism, which was administered by Cardinal Fesch at Fontainebleau, in November, 1810. Hortense selected the abbé Bertrand as her son's governor, Philippe Lebas, a thorough republican, as his principal preceptor, and Col. Armandi became his military instructor. Accompanying his mother to Switzerland and Germany, he familiarized himself at the gymnasium of Augsburg with the German language and literature, and applied himself especially to the study of history and mathematics. From 1824 to 1830 he was with Hortense at Arenenberg. Gen. Dufour having perfected his military training, he became an officer in the Swiss army, and in that capacity was regarded as an adopted citizen of that country. Louis Philippe refusing to allow him to reside in France, he joined the patriots in Italy, where his brother died at Forlì, while he, escaping to Ancona (1831), was prostrated there by a severe illness. He finally reached Paris after great perils, but, being ordered to leave, returned with his mother to Arenenberg. Subsequently he was about to engage in the Polish war of independence, the command of the revolutionary army having been tendered to him, when the fall of Warsaw put an end to that project. A new application to the French government led only to a renewal of the decree of banishment, especially as the death of the duke of Reichstadt in 1832 made him Napoleon's heir, according to the precedence accorded in the emperor's will to the children of Louis and Hortense, of whom he was then the only surviving son. He now devoted himself to literary labors, which kept him before the public as a philosophical writer on political and social subjects, and as an advocate of universal suffrage as the basis of imperialism. In 1836 he covered himself with ridicule by an abortive attempt to overthrow the French government, begun at Strasburg

(Oct. 28-30), which resulted in his arrest and detention at the citadel of Lorient till Nov. 21, when he was conveyed to Brazil, and thence in January, 1837, to New York, where he lived for some time in pecuniary embarrassment. He was at Arenenberg at the time of his mother's death, in October, 1837, after which he voluntarily left Switzerland in order to avoid involving that country in a contest with Louis Philippe, who had insisted on his being expelled. He took up his residence in London, surrounded by partisans, most of whom reaped in the subsequent days of his prosperity the reward of their devotion to him in his adversity. He associated much with the countess of Blessington and Count d'Orsay, and with a number of the English nobility; but pecuniary distress and his political designs affiliated him with less select members of society. His principal mistress was Mrs. Howard, who bore him several children, and for whom he afterward provided handsomely; and while in London he was for the first time introduced by Count Bentivoglio, brother of the countess Walewska, to Eugénie, his future wife. He enlisted support in the press for his imperialistic theories, and published in 1839 the *Idées Napoléoniennes*. His tenacity of purpose and impenetrable bearing, savoring rather of the Teutonic than of the Latin race, had impelled his mother to call him *le doux entêté*, in allusion to his being at the same time placid and stubborn, and gave him special qualifications for the mission of a conspirator. He embarked in August, 1840, for the continent, with the purpose of regaining the French throne; but this enterprise ended as absurdly as the attempt at Strasburg. With Montholon, a companion of Napoleon I. at St. Helena, and about 50 followers, he landed near Boulogne in the night of Aug. 6, displaying a tame eagle; but he failed to rouse the enthusiasm of the troops, and was again arrested, and two months later sentenced by the chamber of peers, despite Berryer's eloquent defence, to perpetual imprisonment. He was confined in the fortress of Ham, where Montholon and Dr. Conneau shared his captivity and assisted him in preparing various publications. Being selected by several Central American states as the president of a projected Nicaragua canal, an application for his release was made in 1846, to which the illness of the ex-king Louis gave additional weight; but Louis Philippe declined to grant the request, and the prince made his escape from Ham (May 25) in the dress of a working man, with the assistance of Dr. Conneau, and reached England. The French ambassador in London, however, refused to provide him with a passport, and he was prevented from attending his father's deathbed. He remained in London till the outbreak of the revolution of Feb. 24, 1848, when he hastily left for Paris, but at the request of the provisional government he went back to England. He repeatedly declined to accept nominations to the constituent assembly, in order, as

he alleged, not to embarrass the government; but being elected by large majorities in Corsica and in three other departments, including that of the Seine, he finally accepted the latter election, which was ratified by the assembly (June 12), despite the decree of the executive commission for his continued banishment. But on his declaring to the president of the assembly "that he would know how to fulfil the duties which the people might choose to impose on him," a popular excitement arose, and he returned to London, resigning his seat. After the sanguinary conflict of June, however, finding himself again reelected by the departments of the Seine, Yonne, Charente-Inferieure, Moselle, and Corsica, he took his seat (Sept. 26) in the constituent assembly, which speedily revoked the decree of banishment. Yet he was distrusted, and an amendment was introduced (Oct. 9) with a view to exclude him from the presidency of the republic. On this occasion he made his first speech, his excessive tameness and composure creating an unfavorable impression, and Thiers called him a wooden head (*tête de bois*). To subsequent attacks he offered the same reserve and silence, declaring that he preferred to show his devotion to France by actual services rather than by rhetoric. He maintained the same attitude during the presidential election, listening to everybody without unbosoming himself to anybody, and seeking to conciliate all parties without identifying himself with any. On Dec. 10, 1848, he was elected president of the republic for four years by 5,434,226 votes, according to the official announcement on the day of inauguration, Dec. 20, Cavaignac, his principal competitor, receiving only 1,448,107. Odilon Barrot became the head of the cabinet; Drouyn de Lhuys, minister of foreign affairs; Falloux, of public instruction; Bixio, the only one who had not been a monarchist, of agriculture and commerce, but retired within eight days; and M. de Maleville, of the interior, who was speedily dismissed, mainly because he had failed to hand over instantly to Louis Napoleon all the telegraphic despatches addressed to him. The sincere republicans soon fell out with the president, on his determining to close political clubs and adopting other reactionary measures. A French army under Oudinot was sent against the Roman republic, and after some combats entered Rome July 8, 1849. Although this project had been initiated by Cavaignac and approved by the assembly, the ultra republicans, under the lead of Ledru-Rollin, attempted to impeach the president on account of this intervention; but his course was approved by the majority. The attempt at insurrection made on June 18 was promptly quelled; but he exasperated the extreme left by proclaiming martial law in Paris, forbidding political meetings, and instituting legal proceedings against the representatives implicated in those disturbances; while at the same time he incurred the displeasure of the conservatives by

seeking to condone for this rigor by releasing over 1,800 persons who had participated in the outbreak of the preceding year. The accession of a number of ultra republican members in 1850 increased the disappointment of the conservatives, and on May 31 they passed a law restricting the universal suffrage which had made Louis Napoleon president; and they further marked their hostility by grudging him an increased allowance, and by appointing a permanent committee to watch over the public interests during the recess of the legislature. This permanent committee was composed exclusively of conservatives; and while several of their leaders conferred with the count de Chambord in respect to a fusion of the two branches of the Bourbons, Louis Napoleon courted popularity with the masses and the army. After a demonstration in his favor by the troops at Satory, near Versailles, Changarnier issued an order prohibiting such manifestations, which the president resented by removing him from the military command of Paris (Jan. 9, 1851), whereupon the assembly passed a vote of censure against the administration. This led to the formation of a new cabinet and to a conciliatory message, which, like most of Louis Napoleon's state papers, was pervaded with a peculiar philosophical vein of thought; but a majority again declined to accord him a larger allowance, and their ill feeling against him was greatly increased by the petitions pouring in from all parts of the country demanding an extension of the presidential term, and by Louis Napoleon's speeches at Dijon and other places, in which he assumed to be the providential protector of France against both legitimists and socialists. Many of the provincial authorities protested against the rejection by the majority of the proposed revision of the constitution for the extension of Louis Napoleon's term of office; and in this conflict between the assembly and the numerous Bonapartists among the people, the president ingratiated himself still more with the latter by proposing, in addition to the abrogation of the law of May 31 restricting the suffrage, the exercise of the franchise after only six months' residence in the place of voting. These measures were rejected by the assembly, and a resolution was at the same time introduced tending to place the military forces of the capital under the control of the president of that body. This capped the climax of the contest, and Louis Napoleon immediately appointed a new prefect of police, M. de Maupas, and a new commander, Magnan. The latter selected a new corps of officers, composed of devoted Bonapartists, and the president declared that in a crisis he would not, like previous chiefs of state, follow the army, but expect it to follow him. The assembly, torn by party wrangling, was unable to concert measures for the defence of the constitution, while the president matured his schemes. Finally, on Dec. 2, 1851,

Louis Napoleon, assisted by Persigny, Morny, Saint-Arnaud, Magnan, Maupas, and other lifelong adherents, overthrew the assembly by military force and took possession of the whole government. During the preceding night and early in the morning of that day about 180 members of the two extreme parties were placed under arrest, and some of them at once sent out of the country; the national assembly was declared to be dissolved, and its place of meeting was guarded by soldiery; universal suffrage was proclaimed, and Paris placed in a state of siege. Several members of both parties in the assembly hastily assembled, but in vain, to protest against the usurpation, and declare the president deposed; resistance was attempted, but without concert or plan, and chiefly resulted in deluging the principal boulevards with the blood of innocent spectators, shot down by the soldiery under Canrobert and others (Dec. 4). Louis Napoleon had made such effective preparations that order was speedily restored. His appeal to the people in the general elections (Dec. 20-21) resulted in the confirmation of his usurpation and his election to the presidency for ten years, by over 7,000,000 against less than 1,000,000 negative votes. He promulgated a new constitution, Jan. 14, 1852, reaffirming the principles of 1789, and declaring organic changes in the form of government to be admissible only by the consent of the people; and on March 28 he relinquished the dictatorship which he had assumed since the *coup d'état*, to resume the office of president. But it soon became manifest, especially from his intimations at Bordeaux on Oct. 9, that he was again bent on disregarding his pledged faith to the republic. The senate, obedient to his behests, voted almost unanimously on Nov. 7 in favor of the restoration of the empire, and he resorted once more to his favorite measure of appealing to the people. The voice of the senate was ratified, Nov. 21-22, by nearly 8,000,000 votes; and on Dec. 2 he ascended the throne as Napoleon III., hereditary emperor of the French, by the grace of God and by the will of the nation. On Jan. 22, 1853, he informed the legislature that, after having become the peer of the anointed heads of old monarchies by the force of new political principles, it would be hardly dignified to gain an artificial admission to their families by intermarriage; and uttering such democratic reflections, he announced his approaching marriage with Eugénie Marie de Montijo, which union was celebrated on Jan. 29 and 30. Although he had won supporters by declaring peaceful intentions, this illusion was speedily dispelled by the Crimean war, in which he embarked with Great Britain, Sardinia, and Turkey. It was alleged that, as the emperor Nicholas had declined to address him as his brother, as is usual among sovereigns, he was the more anxious to join in the war, which resulted in the defeat of Russia. The treaty of peace of March 30, 1856, was concluded in Paris under

the auspices of Napoleon, who came out of this contest with enhanced prestige. The birth of the prince imperial on March 16 increased the festivities of the court, while a large concourse of visitors to the capital added to the commercial prosperity which he had from the first sought to promote, especially by providing occupation for the discontented poor in new public works. He exchanged visits with Queen Victoria, had a friendly interview with the czar in September, 1857, and became the principal mediator between Switzerland and Prussia in the Neuchâtel question. At the same time he gave greater prominence to the navy, and dazzled the public mind by his occupation of New Caledonia and by joining England in the warfare against China, and subsequently by expeditions to Japan and Cochin China, the last resulting in conquest. Attempts had been made upon his life by Pianori and Bellamare in 1855; and another was made in January, 1858, by Orsini and others, chiefly Italians, on the very eve of Napoleon's interference in favor of Italy. Cavour, who had cultivated excellent relations with him during the negotiation of the treaty of Paris in 1856, met him again at Plombières in August, 1858; and on the following new year's day, when the diplomatic corps presented their respects to the emperor, he created a great sensation in Europe by abruptly expressing his regret to Baron Hübnér, the representative of the emperor Francis Joseph, at the altered relations between Austria and France. This was followed at the end of the same month (Jan. 30, 1859) by the marriage of the princess Clotilde, daughter of Victor Emanuel, with Prince Napoleon, and in May by the emperor's formal declaration of war against Austria, which had taken the initiative in attacking Sardinia, while Francis Joseph denounced Napoleon as a revolutionary firebrand. Setting out for the seat of war with the avowed purpose of making Italy free from the Alps to the Adriatic, Napoleon nevertheless brought the contest to an incomplete termination while flushed with the brilliant victories at Magenta (June 4) and Solferino (June 24), and he personally arranged with the emperor of Austria the preliminaries of peace at Villafranca (July 11), mainly resulting in the nominal cession to France of Lombardy, which was at once transferred to Victor Emanuel. This abrupt peace, when it was generally expected that the war would be followed up by the total extirpation of Austrian domination in Italy, was ascribed to his anxiety to close the conflict before the aid of Prussia should enable the enemy to turn the tide of success, to the complications growing out of the continued protection of Rome by the French army, and to a certain reluctance to make Italy too powerful. Cavour, however, despite the stipulations of Villafranca, which were confirmed by the treaty of Zürich (November, 1859), opposed the plan of an Italian confederation proposed by Napoleon, and insisted upon the establishment of the

kingdom of Italy. While ostensibly attempting to have the Italian question settled peaceably by liberal reforms on the part of the pope and the king of the Two Sicilies, and by a congress of sovereigns in Paris, Napoleon allowed Victor Emanuel to extend his dominions; and his tacit connivance with the aggrandizement of Italy was rewarded in 1860 by the cession of Savoy and Nice to France. This led to a protest on the part of Switzerland, and revived in Europe generally suspicions of aggressive designs on his part, though in an interview with the German potentates on June 15, 1860, he strove to allay these apprehensions. Great Britain was now more friendly disposed to him than most other powers, especially as he lost no opportunity to ingratiate himself with Englishmen individually, and concluded in the same year with Cobden personally a commercial treaty in the interest of free trade. This measure, however, alienated from him the good will of the protectionists in France, and was abandoned after his downfall. He also lost ultramontane supporters by his Italian policy, by the suppression of the society of St. Vincent de Paul, by the appointment of M. Renan to a professorship, and by other measures which pleased the liberals, whom he further propitiated by removing (Nov. 30, 1860) some of the restrictions on elections, and enlarging the scope of the legislature and the liberties of the press. The Anglo-French war in China was brought to a successful termination by the capture of Peking in October, 1860; and his prestige in the East was increased by the expedition to Syria (1860-'61), for protecting the Christian populations against a renewal of the Damascus massacres. The emperor was at the zenith of his prosperity at the time of the outbreak of the civil war in the United States. As this had a disastrous effect upon French industry and commerce, short crops aggravating the situation, Napoleon surrendered in favor of the legislature, at the urgent request of Minister Fould, his previous absolute control of the treasury. He recognized the belligerent rights of the Confederate States, but officially informed the United States government (May 16) that he did not consider this as recognizing the former as an independent power. Ostensibly he assumed a conciliatory attitude toward the United States, and repeatedly offered his friendly services for the restoration of peace. He entertained, however, unofficial relations with the Confederate agents, who claimed to have many influential friends of their cause at the imperial court. An expedition projected in June, 1861, by France, England, and Spain, avowedly to obtain material guarantees for claims against Mexico, degenerated after the withdrawal of the two latter powers (April, 1862), under Napoleon's sole direction, into a war of conquest against that republic; and in April, 1864, he established the Hapsburg prince Maximilian on the throne of Mexico as emperor. This was rep-

resented as the initiation of Napoleon's proposed supremacy of the Latin race, of which he wished to become the arbiter in the new world as in the old; but the increasing victories of the United States made him afterward disclaim all purpose of territorial acquisitions. At home he continued to make himself acceptable, especially to the money-making classes, officeholders, contractors, and speculators, who profited by military and naval expeditions, by railways, and by all the other stupendous enterprises of the period; and the embellishment and enlargement of the capital gave employment to many paupers, while little or nothing was done for the mental and moral elevation of the masses, and the whole aim of the emperor seemed to be to dazzle by splendor and luxury, and by material grandeur at home and visions of glory abroad. But the drain upon his military resources in Mexico was regarded as paralyzing his strength for the contingency of war in Europe, and at the same time made, together with the other costly expeditions, heavy inroads on the treasury. He began also to feel uneasy at the increasing power of Prussia; and to counteract her *entente cordiale* with Russia, he warmly advocated in 1863, in union with England and Austria, the treaty rights of Poland; but as these powers declined to join him in ulterior measures, England especially refusing to take part in a congress which he proposed for the settlement of this and other questions, he had to content himself with a barren declaration of sympathy for the Polish patriots. While his political situation in Paris was compromised by official tampering with the elections, and by the greater dignity imparted to the opposition in the *corps législatif* by the accession of Thiers, Berryer, and other influential statesmen, he was obliged to remain a passive spectator of the Schleswig-Holstein war and the consequent aggrandizement of Prussia. After having at first made an unavailing effort to prevent this war by mediation, he withdrew (January, 1864) from a conference of the powers at London, disguising his dissatisfaction with the progress of these events by pretending to encourage the application of his theory of nationalities in favor of the Schleswig-Holstein people shaping their own destinies. The ignominious end of the Mexican expedition, from which the cabinet of Washington had urged him to withdraw, especially after the termination of the civil war in 1865, and the Prusso-Italian coalition against Austria in 1866, which he resented by denouncing the obsolete character of the treaty obligations of 1815, inflicted still greater injury upon his prestige; while the independence of Italy from France was further exhibited by Napoleon's withdrawal of his troops from Rome at the end of 1866, in accordance with the convention of 1864. His participation in the peace negotiations between Austria and Italy after the overwhelming defeat of the former power by the Prussians at Sadowa (July 3), resulted in the

nominal cession of Venetia to France and in its immediate transfer by Napoleon to Victor Emanuel; but this afforded a poor consolation for the loss of influence, which had passed from his hands to those of Germany, under the lead of Prussia. The parliamentary opposition, led by Thiers, increased in proportion to his vanishing reputation, and the blunders of his foreign policy as well as the maladministration of financial affairs were unsparingly exposed. His repeated efforts in the course of 1866 to recover his lost ground by acquisition of German or Belgian territory, in consideration of his allowing Prussia to take the lead in united Germany, were unavailing against Bismarck's opposition; and he was also disappointed in his hope of creating a division between the South and North German states; so that all he could obtain after a grave conflict with Prussia in relation to Luxemburg, and subsequent negotiations with Holland for the acquisition of that territory, was its neutralization at the conference of London (May, 1867). He endeavored nevertheless to explain away in his message to the legislative body the dangers of German consolidation, but proposed at the same time a considerable increase of armaments. The execution of Maximilian in June, 1867, shortly after the departure of the last French troops from Mexico, became known in Paris at the time when Napoleon was entertaining, during the great exposition, almost all the crowned heads of Europe, including the sultan and the czar. The emperor went to Salzburg in August to condole with Francis Joseph on the tragical death of Maximilian, and this interview was regarded as a pledge of more intimate relations between the two emperors. He soon afterward sent French troops to Rome for the protection of the pope against the Garibaldians, and insisted upon Victor Emanuel's joining his efforts in conformity with the convention of 1864; but the emperor's subsequent appeal to the European powers to settle the Roman question by a congress in Paris was not heeded. Despite his constant manipulation of public opinion, the general elections of 1868 showed a defection of 200,000 voters since 1863; and the new press law, adopted after stormy debates, and regarded as affording somewhat greater liberty, resulted only in increasing the clouds that had been gathering round his throne and in the creation of many new journals, the most conspicuous of which in its invectives was Rochefort's *Lanterne*, whose first nine weekly issues reached a circulation of over 1,150,000. Other journals were almost equally bold, though much more decorous; and 64 editors were sentenced to imprisonment between May 11 and Dec. 31, 1868. According to the new law of Feb. 1, 1868, the military force, including the mobile guards, was brought up to 1,350,000 men. Yet on opening the new legislative session on Jan. 18, 1869, the emperor boasted of his friendly relations with foreign powers and of the prosper-

ity of the country. More than ever in need of the support of the masses, he followed up his various measures for the working classes by suppressing early in 1869 the *livrets* or service books which had subjected artisans to vexatious formalities. The controversy with Belgium in regard to the transfer of a Belgian railway to a French company, which for a time threatened complications, was amicably settled in April, but great agitation continued to prevail in Paris. The new elections at the end of May were attended with tumults in many localities, the opposition carrying Paris, Lyons, Marseilles, and other cities, though the official influence in the interior, together with the votes of the peasantry and part of the clergy, resulted in an aggregate vote in favor of Napoleon. Thiers, Favre, and Simon, however, were reelected; Gambetta, Bancel, and Raspail were returned to reinforce the ultra radicals; and Rochefort himself was finally elected in one of the metropolitan districts, at the same time with Crémieux and Emanuel Arago; while Émile Ollivier, a former liberal who had adhered to Napoleon, was defeated in Paris, and had to accept a seat for one of the departments. The aggregate of votes cast for the emperor had dwindled down to less than 5,000,000, while the opposition, including those opposed to personal government though in favor of a constitutional empire, exceeded 3,000,000. Riotous demonstrations ensued (June 7-11) in Paris and other cities, amid acclamations in favor of a republic and against Napoleon. Over 1,000 persons were arrested, and the military had to restore order in Paris, Nantes, and Bordeaux. To calm the excitement, the emperor proposed liberal changes (July 12) after the opening of the legislative body; dismissed Rouher, his strongest partisan, from the ministry; appointed a new cabinet to mark the transition from personal and arbitrary to the new projected parliamentary and constitutional government; and promulgated an amnesty for political exiles, which measure resulted in bringing back to France some of his most inveterate enemies. The *senatus consultum* embodying the new reforms was adopted Sept. 6; but the emperor would not convoke the new session on the day prescribed by the new law. The opposition, led by Favre, proposed to take the initiative in opening it; but in view of the public exasperation, they limited their demonstration to the issue of a protest (Oct. 18) against what they characterized as Napoleon's new insult to the nation, and calmly awaited the inauguration of the legislature by the emperor himself, which took place Nov. 29. Ollivier now came forward as the principal spokesman of the new constitutional régime, with about 120 followers, the rest of the members being divided among the various shades of conservatives and radicals. In his exposition of foreign policy the emperor expatiated on the advantages of the Suez canal, which he had labored to promote, and on the Egyptian-

Turkish complication, in regard to which he sided with England in maintaining the rights of the sultan without compromising the interests involved in the authority of the khedive. Ollivier became prime minister on Jan. 2, 1870, and one of the first measures of the new administration was to remove Haussmann, whose administration of the prefecture of the Seine and stupendous enterprises had contributed greatly to the embellishment and enlargement of Paris, but also to the detriment of integrity and financial stability, and to the disadvantage of the poor, whose humble dwelling places had been pulled down to make room for new boulevards and squares; while Odilon Barrot was appointed chairman of the committee of decentralization. Additional odium was cast upon Napoleon by the assassination of Victor Noir by Prince Pierre Bonaparte, and by the latter's acquittal of the charge of murder at Tours, March 27. Yet he received an affirmative vote of over 7,000,000 on the *plébiscite* of May 8, in approbation of his reform measures, although Paris returned over 180,000 adverse votes, including those of many soldiers, and the majority in most of the large cities remained equally hostile to the emperor. Uneasiness in regard to foreign relations was revived by the appointment as minister of foreign affairs of the duke de Gramont, who while French ambassador in Vienna had been noted for his hostility to Prussia. Ollivier nevertheless persisted (June 30) in reassuring the country in regard to uninterrupted friendly relations with foreign powers. Great excitement, however, prevailed shortly afterward, when it became known that the crown of Spain had been offered to Prince Leopold of Hohenzollern, a relative of the king of Prussia, and both Ollivier and Gramont declared (July 6) in the legislative body that such a candidature, agreed upon without the knowledge of the French government, would be injurious to the honor and the influence of the French nation. The emperor instructed Benedetti, his ambassador in Berlin, to require King William, who was at that time (July 9) at Ems, to prohibit Prince Leopold from accepting the Spanish crown. Despite the latter's voluntary withdrawal, the emperor was not satisfied, and insisted upon a personal pledge from the king of Prussia that no prince of Hohenzollern would be in future a candidate for the Spanish throne. It now became manifest that the emperor, despairing of sustaining his power at home and of recovering his standing abroad, was bent on retrieving his fortunes on the battlefield, and on wreaking revenge upon Prussia for the success by which she had exalted the glory of Germany and dimmed that of France. Bismarck, the Prussian prime minister, declined to submit the emperor's new pretensions to the king; and as Benedetti was nevertheless instructed to intrude them upon the Prussian monarch personally, the latter declined to give another

interview to Napoleon's representative. The next day (July 14) Benedetti was recalled by the emperor, and Baron Werther from Paris by the Prussian king. Preparations for war were immediately made on both sides. The Germans manifested the wildest enthusiasm in resenting what they called the arrogance of France, and, contrary to Napoleon's expectations, the South German states promptly declared their readiness to join the North German confederation. The mediation of England, offered by Lord Loftus, the British ambassador, was declined in Berlin until Napoleon should first accept it; and a subsequent mediatorial effort of Pius IX. likewise fell to the ground. Napoleon took the initiative by formally declaring war on July 19 through his chargé d'affaires Le Sourd, basing his declaration, first, upon the insult offered at Ems to Count Benedetti, the French minister, and its approval by the Prussian government; secondly, upon the refusal of the king of Prussia to compel the withdrawal of Prince Leopold's name as a candidate for the Spanish throne; and thirdly, upon the king's persistence in giving the prince liberty to accept the throne. The extraordinary military appropriations demanded by the emperor were unanimously accorded by the senate, and with but a few dissenting votes by the legislative assembly; but as considerable time was lost in the preparations, the Germans were left at liberty to concentrate overwhelming forces on the French frontier, King William leaving Berlin on July 31, three days after Napoleon's departure for Metz. The first movement of importance began on Aug. 2, when Gen. Frossard, with about 30,000 men, advanced from St. Avold against Saarbrück. On the advance of the French, the small Prussian garrison of that city retired to the adjoining heights, and was compelled to withdraw to the right bank of the Saar. On taking possession of the heights, but not of the town of Saarbrück, the emperor sent to Eugénie, whom he had left in Paris as regent, a sensational despatch containing a grandiloquent passage on the prince imperial's baptism of fire. But grotesque as this announcement was, it was the only one sent by him that did not savor of defeat. The successive German victories creating great commotion in Paris, he was soon obliged (Aug. 8) to relinquish the command of the armies, and after a few days spent with Bazaine he joined MacMahon at Châlons. The corruption which had infected the public service of the empire had impaired the efficiency of the military organization, and the generals, mainly trained in the warfare against Arabs in Algeria, could not cope with the superior organization of the Germans. Napoleon was overwhelmed by defeat after defeat, and on Aug. 31 he issued at Sedan his last proclamation to the army, exhibiting, though striving to conceal, his desperation. He had already a few days before provided for the safety of the prince imperial by sending him to Belgium; and in the afternoon

of Sept. 1, when the French were everywhere beaten, Wimpffen proposed to the emperor, who was said to have deliberately exposed himself to death in the thickest of the fight, to save himself from capture by breaking through the German lines at Carignan. Napoleon would not risk the lives of the soldiers in what he regarded as a hopeless attempt, and also declined to accept Wimpffen's resignation. Soon after 5 P. M. he sent a colonel with a white flag to the headquarters of the enemy. Suddenly the firing ceased. The Germans shouted, "Victory! the emperor is there." The king of Prussia sent Lieut. Col. Bronsart to Sedan to demand an unconditional surrender, upon which the emperor despatched his aide-de-camp, Gen. Reille, to the royal headquarters with the following letter: "My brother: Since it has not been vouchsafed to me to meet death at the head of my troops, I surrender my sword to your majesty." In order to obtain if possible more lenient conditions of capitulation than the Germans were disposed to accord, the emperor left Sedan at 5 A. M. on Sept. 2, Bismarck hastening to meet him on the road between Sedan and Donchéry, in a small house near the latter place. The king, however, consented to see the emperor only after the ratification of the capitulation between Moltke and Wimpffen. Preceded by an honorary escort of Prussian cuirassiers, and accompanied by Bismarck, the emperor had the same night an interview of about 15 minutes with the king of Prussia at the castle of Bellevue, near Frénois, and the victor assigned to his captive the castle of Wilhelmshöhe, near Cassel, as a residence. He left Bellevue on the morning of Sept. 3 for the Belgian frontier with a Prussian escort, the Belgian general Chazal escorting him to the German border; and in the evening of Sept. 5 he arrived at Wilhelmshöhe. During his residence there the empress of Germany showed him many delicate attentions. On the news of the emperor's capitulation Jules Favre at once proposed his deposition in the legislative body, and in the confusion which ensued during the proclamation of the republic (Sept. 4) the empress regent fled to England. Napoleon protested (March 6, 1871) against the decree of the national assembly at Bordeaux of March 1, which confirmed his expulsion and that of his dynasty from the throne, and made him responsible for all the calamities of the war and for the dismemberment of France. He was released by the emperor William on March 19, and joined Eugénie and the prince imperial at Camden house, Chiselhurst, where he was temporarily buried. On May 12, 1872, he wrote to Gen. Wimpffen assuming the sole responsibility for the surrender at Sedan; and a pamphlet entitled *Des causes qui ont amené la capitulation de Sedan, par un officier attaché à l'état major général* (Brussels, 1870), has been ascribed to him. Queen Victoria, and especially the prince of Wales, and the English generally, with whom he had always been popular personally, soothed his exile

by considerate attentions; and his funeral was numerously attended by the English and by French partisans of his dynasty. He published *Histoire de Jules César* (2 vols., 1865-'6), which is still unfinished; and his miscellaneous writings are contained in *Œuvres de Napoléon III.* (5 vols., 1854-'69), *Œuvres militaires* (3 vols., 1856), and *Œuvres posthumes* (1873).—See *Histoire du second empire*, by Taxile Delord (vols. i. to iii., 1869-'72), and *Napoléon III., eine biographische Studie*, by Gottschall (2d ed., 1871). The best known publications adverse to Napoleon are Victor Hugo's *Napoléon le Petit* (Brussels, 1852), and *Les propos de Labiénus*, by Prof. Rogeard (Paris, 1865).—**Eugénie Marie de Montijo**, wife of the preceding, born in Granada, May 5, 1826. Her father, Count Montijo, who died in Madrid in 1839, was a grandee of Spain, whose origin has been traced to the Porto-Carrero family of Genoa, which, after settling in Spain in the 14th century, formed connections with many illustrious houses, whence Eugénie inherited numerous Spanish titles of nobility. Her mother, Maria Manuela Kirkpatrick Closeburn, was descended from a Roman Catholic family of Scotland who sought refuge in Spain after the fall of the Stuarts. After spending her childhood in Madrid, Eugénie was sent to school in Toulouse and Bristol, and travelled much with her mother under the name of Countess Teba, residing some time in London. Her beauty, grace, and accomplishments having attracted the attention of the future emperor during his residence in England, she became his wife, Jan. 29, 1853, and contributed greatly to the brilliancy of the imperial court. She prevailed upon the municipality of Paris to devote a wedding present of the value of 600,000 francs, intended for her, to the endowment of a female college, and further devoted to charities 100,000 out of 250,000 francs presented to her by her husband on the same occasion. She gave birth to the prince imperial March 16, 1856, and the prospective right of regency was conferred on her in February, 1858. Her support was courted by the ultramontanes in respect of the Italian and Roman questions and the Mexican invasion; and in 1865, while her husband was in Algeria, her position as regent was complicated by Prince Napoleon's hostility to the pope, to whose interests she was zealously devoted. After having in previous years accompanied her husband to the English court, she went with her son to Corsica in 1869 to attend the inauguration of the monument of Napoleon I.; and in October of that year she set out on a journey to the East by way of Venice to attend the opening of the Suez canal, receiving great attentions everywhere. In the same year she endowed the geographical society of Paris with 200,000 francs as a foundation for an annual prize of 10,000 francs to the most eminent French explorer or discoverer. She assumed the regency after the emperor's departure for the seat of war in 1870, and received the first news of his surrender at Se-

dan through Prince Metternich, the Austrian ambassador, whose wife was one of her most devoted friends, and formerly conspicuous, with the empress, Mme. de Pourtalès, Mme. de Gallifet, and other brilliant women, among the most famous leaders of gay and fashionable entertainments. She received no tidings either from her minister Palikao or from her husband; but Pietri, the prefect of police, in the afternoon of Sept. 3, warned her of the insecurity of her position, and his despatch was still on her table when a few hours after her departure the mob invaded her apartments. Metternich urged her to flee in the most pressing manner, and the Tuileries was in the greatest confusion when she left the palace after midnight, deserted by her attendants and accompanied by Metternich, the Italian minister Nigra, the countess Walewska, M. de Lesseps, and her aged secretary, Mme. Lebreton. Plainly attired, the empress was recognized only by a boy, whose exclamation passed unnoticed, and she entered a public carriage in a street near the imperial residence, at the same moment when a crowd of nearly 1,000 persons passed by her uttering violent outcries against the emperor. Eugénie, the countess Walewska, Prince Metternich, and one of the latter's attachés rapidly drove to the railway station, intending to proceed to England. After spending a few days with the Hagvorst family near Brussels, the ex-empress proceeded to Ostend and Dover, and thence to Hastings, where she met her son, with whom she left for Torquay, and on Sept. 24 arrived at Chiselhurst. Napoleon joined them in March, 1871, and she continued to reside there after his death.—**Napoléon Eugène Louis Jean Joseph**, prince imperial, son of Napoleon III. and Eugénie, born in the Tuileries, March 16, 1856. He received a careful education, and accompanied his father to Metz on the outbreak of the Franco-German war, and thence to Saarbrück, where, according to Napoleon's despatch to Eugénie, he received his baptism of fire. As the military situation became critical, the emperor provided for the safety of his son by sending him in August to Belgium, and subsequently he joined his mother in England. He is a youth of delicate frame and winning manners, and bears a much greater resemblance to his mother than to his father.

BONAVENTURA, **Saint** (GIOVANNI DI FIDANZA), a cardinal and doctor of the Roman church, born at Bagnarea in Tuscany in 1221, died in Lyons, July 15, 1274. He entered the order of St. Francis in 1243, studied in the university of Paris, was appointed professor of theology there in 1253, and in 1256 elected general of his order. He reconciled the differences among the cardinals on the death of Clement IV., and they chose Gregory X. on his advice in 1271. That pope made him bishop of Albano in 1273 and cardinal in 1274. He died during the session of the second council of Lyons, to which he had been sent as papal legate, and his funeral was attended by the supreme pontiff, accompanied by a brilliant retinue of cardinals

and kings. He was canonized by Sixtus IV. in 1482, and declared by Sixtus V. in 1587 the sixth in rank among the great doctors of the church. The sublime and mystical thoughts which abound in his writings gained him the title of the seraphic doctor. The Franciscans regard him as one of their most learned theologians, and rank him with Thomas Aquinas. He is the patron saint of the city of Lyons, where he was buried. His works include a commentary on the *Magister Sententiarum* of Peter Lombard, the two manuals of dogma called the *Breviloquium* and *Centiloquium*, the *Itinerarium Mentis in Deum*, the *Reductio Artium in Theologiam*, the *Biblia Pauperum*, a life of St. Francis, and various songs and devotional and exegetical treatises. They are of a strong mystical tendency, but fervent in spirit and practical in their teachings. They have been published at Rome (8 vols. fol., 1588-'96), Lyons (7 vols. fol., 1688), and Venice (14 vols. 4to, 1752-'6).

BONCHAMP, Charles Melchior Artus, marquis de, a French soldier, born at Jouveteil, Anjou, about 1760, died near Chollet, Oct. 18, 1793. He served in the American war of independence, and on his return to France resigned and remained faithful to Louis XVI. After the outbreak of the insurrection in Vendée (March, 1793), his tenantry compelled him to place himself at their head. He commanded the insurgent troops in Lower Poitou and in Anjou, and was wounded in the attack on Nantes and on other occasions, and defeated Kléber near Torfou. He was mortally wounded near Chollet, and died next day on the retreat, after having prevented his soldiers from retaliating upon the prisoners of war. The *Mémoires de Mme. de Bonchamp sur la Vendée*, edited by Mme. de Genlis (Paris, 1823), are regarded as good authority, though ultra-royalist.

BOND, in law, an instrument in writing and under seal, whereby one person, who is called the obligor, acknowledges himself bound to another, who is called the obligee, for the payment of a specified sum of money. If this be the whole, it is called a simple bond; but usually the sum mentioned is specified by way of penalty only, and a condition is underwritten which constitutes the real contract, and which may be for the payment of money, or for any other lawful act to be done or performed by the obligor or by any other person, and which when done shall discharge the penalty. To constitute a valid bond, the obligor must be competent to contract, and he must seal and deliver the instrument; he need not sign, though usually this formality is observed. The seal is evidence that it is given upon sufficient consideration. A bond has some advantages over simple contracts, or those which are not under seal, the chief of which is that, under the statutes of limitation, the remedy by suit thereon is not so soon barred; 6 years being in general the period in the case of simple contracts, and 10, 15, or 20, in different states, in the case

of bonds. At common law, also, contracts under seal were entitled to precedence in the distribution of estates of deceased persons. In a suit upon a bond the obligee recovers judgment for the penalty, but to be discharged upon payment of the actual damages sustained by non-performance of the condition, which damages are assessed by the court or jury and constitute the real measure of liability. A bond is not negotiable, and though it may be assigned, the assignee must at common law sue upon it in the name of the obligee.

BOND, a S. W. county of Illinois, intersected by Shoal creek and its branches, and touched on the S. E. corner by Kaskaskia river; area, about 400 sq. m.; pop. in 1870, 13,152. The St. Louis, Vandalia, Terre Haute, and Indianapolis railroad passes through the county. The surface is moderately uneven, and occupied by beautiful prairies and woodland in equal proportion. The soil is fertile. Coal is found near Shoal creek. The chief productions in 1870 were 369,325 bushels of wheat, 1,064,052 of Indian corn, 461,097 of oats, 19,338 tons of hay, and 87,259 lbs. of wool. There were 6,481 horses, 3,618 milch cows, 10,233 sheep, and 16,907 swine. Capital, Greenville.

BOND, Thomas Emerson, an American physician, editor, and preacher, born in Baltimore, Md., in February, 1782, died in New York, March 14, 1856. After studying in the medical school of the university of Pennsylvania, and taking his degree at the university of Maryland, he returned to Baltimore to practise medicine, and was soon called to a professorship there. While practising medicine he was likewise licensed as a local preacher in the Methodist Episcopal church. Trained to a vigorous style by faithful study of the English classics, Dr. Bond was peculiarly fitted to take active part in the theological questions that agitated the Methodist church from 1816 to 1830. In 1830 and 1831 he conducted the "Itinerant," in which he defended the polity of the Methodist Episcopal church against those views of church government that culminated in the secession of the Methodist Protestant church. His reputation is chiefly owing to his editorial management of the "Christian Advocate and Journal," the chief organ of the M. E. church. He conducted this journal for 12 years, being editor-in-chief at his death. He published an "Appeal to the Methodists" (8vo, 1827), and "Narrative and Defence" (8vo, 1828).

BOND. I. William Cranch, an American astronomer, born in Portland, Me., Sept. 9, 1789, died in Cambridge, Mass., Jan. 29, 1859. He was brought up by his father to the trade of watch-making, but devoted much of his time from early youth to studying astronomy. He established a private observatory at Dorchester, Mass., and gained considerable reputation by his discoveries, and in 1838 was selected by the United States government to make observations for the use of an expedition to the South sea. He superintended the construc-

tion of the observatory of Harvard university in 1839, and became its director when completed. From that time he was constantly engaged in astronomical observations and studies, and published the results in the "Annals of the Observatory of Harvard College." He also invented a device for visibly measuring time to a small fraction of a second, and was among the first to use photography as a means of recording the aspects of heavenly bodies. He received the degree of A. M. from Harvard university in 1842, and became a member of the academy of arts and sciences, of the philosophical society, and of the royal astronomical society of London. **II. George Phillips**, son of the preceding, born at Dorchester, Mass., May 20, 1825, died in Cambridge, Feb. 17, 1865. He graduated at Harvard college in 1845, and became an assistant to his father in the observatory, succeeding to its full charge on the latter's death. He wrote several valuable astronomical works, among which are a "Treatise on the Construction of the Rings of Saturn," and the "Elements of the Orbits of Hyperion and the Satellite of Neptune." The satellite of Neptune and the 8th satellite of Saturn were discovered by himself and his father. He received a gold medal from the royal astronomical society for a work on Donati's comet.

BONDI, Clemente, an Italian poet, born at Mizzano, near Parma, in 1742, died in Vienna in June, 1821. He acquired renown in 1773 by his *Giornata villarecia*, published in Parma, where he was professor of rhetoric. His ode relative to the suppression of the society of Jesus, which event took place shortly after his admission to it, giving offence to influential parties, he fled to Tyrol, and subsequently became a protégé of the Austrian archduke Ferdinand, acting as librarian and tutor. In Vienna he instructed the wife of the emperor Francis in history and literature. His works chiefly consist of celebrated translations of Virgil's *Æneid* and Ovid's *Metamorphoses*, and of lyrical, didactic, satirical, and other poetry, which bears some resemblance to that of Metastasio. A complete edition of his original poetry was published in Vienna in 1808, in 3 vols.

BONDOD, a kingdom of Senegambia in W. Africa, between the Senegal and the upper Gambia. The surface of the country, which is generally flat, save in the southern and central parts, where it rises into hills of moderate height, is covered with vast forests and low stunted bushes. From the hills torrents descend during the rainy season to the Senegal and Falémé rivers. In the vicinity of the towns, where the forests have been cleared away, the soil is found to be light and productive. Cotton, grain, rice, indigo, tobacco, and pepper are cultivated with some industry, while different varieties of fruit are found in great profusion. The climate is warm, but not unhealthy. The population, consisting chiefly of Foola and Mandingoes, is estimated at about 1,500,000. The Foola are the dominant tribe. The

people are professedly Mohammedans, but not very strict. In every town there are schools in which the reading and writing of Arabic are taught. The people are of a light copper color,

Bondodos.

and in form and feature resemble the Europeans more nearly than any other tribe of W. Africa, except the Moors. The king possesses absolute power, and has under his command a considerable body of troops. The capital town is Bulbani (pop. about 3,000), situated in an extensive plain at the foot of a range of rocky hills. It is surrounded by a clay wall pierced with loopholes. The houses are small and irregular; the streets narrow, crooked, and dirty. The useful arts are held in high esteem, and a good trade is carried on with some of the Moorish territories. One of the towns, Samecocolo, is famous for its skilful workers in iron and gold.

BONE, the substance which forms the internal skeleton of man and the vertebrated animals, constituting the framework of support, the levers by which force is exerted and locomotion performed, and the boxes or cages in which are enclosed the internal organs. The bony parts of the vertebrated animals are very different in structure and composition from the hard external skeletons of the invertebrata. Bone consists of an organic and an inorganic material, which may be obtained separately by the following simple processes: steep a bone in dilute muriatic or nitric acid; the inorganic or earthy matter is dissolved out, and the organic substance remains, retaining the original size of the bone, and easily bent. In this way is obtained the cartilaginous basis of the bone, on which its shape depends. On the contrary, if a bone be subjected to a strong heat, the organic or animal part is burned out, and the earthy part remains, retaining its form, but

crumbling to pieces at the least touch. To the earthy part, which consists principally of phosphate and carbonate of lime, 51 per cent. of the former and 11 per cent. of the latter, the bone owes its hardness, density, rigidity, and white color; to the animal part, principally cartilage, or some form of gelatine, about 32 per cent., it owes its strength of cohesion. These proportions vary at different ages: in the child, the animal matter forms nearly one half of the bone, accounting for its greater flexibility and the less liability to fracture at this age; in the old, the earthy matter is about 84 per cent., explaining the great brittleness and easy fracture of the bones in aged persons. In the disease called rickets, common among the ill-fed children of the poor in Europe, but somewhat rare in America, there is a deficiency in the deposit of earthy matter, rendering the bones so flexible that they may be bent almost like wax. The power of bone to resist decomposition is remarkable: fossil bones deposited in the ground before the appearance of man upon the earth have been found by Cuvier exhibiting a considerable cartilaginous portion; the jaw of the Cambridge mastodon was found by Dr. C. T. Jackson to contain 42.6 per cent. of animal matter, and cartilage obtained from the same specimen by means of dilute acid was readily converted into gelatine, and made a good glue; a portion of one of the vertebral spines of Dr. J. C. Warren's mastodon was found to contain 30 per cent. of animal matter. The chemical constitution of bone is shown in the following analyses by Berzelius and Marchand:

1. Organic or animal matter.....	33.80	33.26
Phosphate of lime.....	51.04	52.26
Carbonate of lime.....	11.80	10.21
2. Inorganic or earthy constituents.		
Fluoride of calcium.....	2.00	1.00
Phosphate of magnesia.....	1.16	1.05
Soda and chloride of sodium.....	1.20	1.17
Oxide of iron and manganese, and loss.....		10.5
	100.00	100.00

Some recent authorities deny the existence of fluoride of calcium in bone. Bones are not solid. Make a section of almost any bone, and two kinds of structure are seen: one dense, firm, and compact, on the exterior surface; the other loose, spongy, enclosing cells or spaces communicating freely with each other, in the interior of the bone, and surrounded by the more compact tissue. The loose structure abounds in the ends of bones, securing at the same time greater lightness and sufficient expansion to form the joints, while in the shaft or central portion, where strength is most needed, the compact tissue is more developed. Bones are of different forms, according to the uses to which they are to be applied: some are long, as in the limbs, and these are the principal levers of the body; others are flat and thin, composed of two layers of compact tissue, with an intervening cellular structure, destined to enclose cavities. Bones have also a variety of eminences and depressions, for the

attachment of muscles, the protection of nerves and vessels, &c.; these eminences, or processes, are well marked in proportion to the muscularity of the subject. In females and feeble men the bones are light, thin, and smooth, while in the powerfully muscular frame the bone is dense and heavy, and every prominence is well developed. Exercise is as necessary to the strength of a bone as it is to the strength of a muscle; if a limb be disused from paralysis, or the body be prostrated by long disease, the bones waste as well as the soft parts. The external surface is perforated by numerous minute openings, which transmit the arteries and veins to the interior; this surface is covered by a firm tough membrane, the *periosteum*, composed of densely interwoven white fibrous tissue. The cells, or *cancelli*, of the spongy portions of bone, are made up of thin and inosculating plates of osseous tissue, enclosing spaces between them which are filled with marrow or *medulla*; these are lined with a delicate membrane. On a superficial observation it appears as if the plates of the cancellated structure were arranged without definite plan; but the researches of Prof. Jeffries Wyman and others show that the cancelli of such bones as aid in supporting the weight of the body are arranged either in the direction of that weight, or in such a manner as to support and brace those cancelli which are in that direction. The arrangement of these bony plates in the lumbar vertebrae, the neck of the thigh bone, the tibia, and the ankle and heel, is of itself enough to indicate that man, alone of animals, naturally assumes an erect position. This relation is most evident in the above-mentioned bones, and in the adult, it being less observable in youth and old age. There is no real difference between the compact and the spongy structure of bone, the degree of condensation being the only distinction. The cells of the cancelli communicate freely with each other. In the long bones the marrow is not contained in cells, but in one central medullary canal, lined by a membrane. Both the periosteum and the medullary membrane are abundantly supplied with blood vessels, and are therefore intimately connected with the nutrition of the bone, and their destruction to any great extent leads to the death of the part in contact with them.—Microscopic examination can alone explain the intimate structure of bone. If a thin transverse section of a long bone, as the *femur*, be examined under the microscope, the compact tissue will present several dark circular or oval spots, surrounded by numerous concentric lines; in these lines will be perceived minute black spots, with other lines leading from them in various directions. The larger oval or circular spots are the openings of vascular canals, called "Haversian," from their discoverer, Clopton Havers; these canals are numerous, taking a course parallel to the axis of the bone, joined together by free inosculations of short trans-

verse branches; they thus form a network of tubes for the minute vessels which they convey and protect. According to Todd and Bowman, the arteries and veins usually occupy distinct Haversian canals, a single vessel being distributed to each. The canals conveying the veins are said to be the larger, and to present at irregular intervals, where two or more branches meet, pouch-like sinuses which serve as reservoirs to delay the escape of the blood; in some of the irregular bones, as in those of the skull, the venous canals are extremely tortuous, running chiefly in the cancellated structure, there called *diploë*. The Haversian canals vary in diameter from $\frac{1}{100}$ to $\frac{1}{300}$ of an inch, the average being about $\frac{1}{150}$, and their ordinary distance from each other about $\frac{1}{10}$ of an inch. This whole apparatus of canals is only an involution of the surface of the bone, that the vessels may come into a more free contact with it; as they communicate internally with the medullary cavity, externally with the periosteal surface, and also with the cancellary medullary cells, the network of nutrient vessels is very complete. But, as if this arrangement were not enough to secure the nourishment of such a hard tissue as bone, and so far removed from immediate contact with blood vessels, there is a still more curious and delicate apparatus of microscopic cavities. Around the Haversian canals will be noticed the appearance of delicate *lamellæ* of bone, more or less concentric; these, with the lacunæ mentioned below, are the most essential constituents of true and fully developed bone, the medullary cells and Haversian canals being merely definite spaces existing between the lamellæ. It is principally by the successive development of new lamellæ that bones increase in diameter, being usually deposited in the direction of the axis. A transverse section, therefore, would present under the microscope the following arrangement of lamellæ, as given by Hassall: 1, several layers passing entirely round the bone; 2, others encircling each Haversian canal; and 3, irregular and incomplete lamellæ occupying the angular spaces between those concentrically arranged. The lamellæ of the Haversian canals, however, are not exactly concentric, as commonly described, but incomplete and running into one another at various points, a necessary consequence of the irregular distribution of the lacunæ. The Haversian systems generally run in the direction in which the tissue requires the greatest strength. With the previously mentioned arrangement of the cancellated structure, the Haversian canals more fully display the wonderful adaptation of means to ends, combining mechanical advantages with the best provisions for the nutrition of the tissue. The number of lamellæ passing entirely round the bone is generally less than 12, and those encircling each Haversian canal vary from 2 or 3 to more than 12, the smallest canals having the fewest lamellæ. The lamellæ, according to the best observers, appear to

consist of a delicate network of fibres in sets, the fibres of each set running parallel, but crossing the others obliquely; some have supposed that they are produced by the union of a number of diamond-shaped cells, and not by the crossing of fibres; the first opinion is probably the true one. Distributed through the cancellated and compact portions of bone occur numerous black specks in the lines of the lamellæ; these are the *lacunæ*, or bone corpuscles, the most peculiar and characteristic microscopic form to be found in bony tissue. They differ somewhat in form in different animals, but are always more or less flattened, elongated, ovoid bodies, with numerous branches and radiating filaments passing out from them and communicating with those in the adjacent lamellæ. In the dried bone the lacunæ are empty, owing to the decomposition

FIG. 1.—Transverse section of bone in the neighborhood of two Haversian canals, *a a*; *b*, lacunæ.

FIG. 3.—Lacunæ, *c*, and canaliculi, *d*, very highly magnified.

and shrinking of the soft parts, and the branched lines running out from them appear as minute canals or *canaliculi*; but in the fresh condition they are both undoubtedly filled with a

soft organized substance, forming an interlacing network of bone corpuscles and filaments, destined to absorb nourishment from the blood vessels occupying the Haversian canals. The bone corpuscles have an average length of $\frac{1}{1000}$ of an inch, and they are usually about one half as wide and one eighth as thick. The diameter of the pores, or canaliculi, is from $\frac{1}{20,000}$ to $\frac{1}{12,000}$ of an inch.—From the researches of Mr. Tomes and Mr. Quekett it appears that the ultimate structure of bone consists of a congeries of granular particles, deposited in an organized matrix; these granules are often distinctly visible, without any artificial preparation, in the substance of the delicate spicula of the cancelli, varying in size from $\frac{1}{3000}$ to $\frac{1}{4,000}$ of an inch. The *periosteum*, a dense, fibrous membrane, richly supplied with blood vessels, covers the external surface of all bones, with the exception of their articular extremities. The vessels of bone are supplied from the periosteum, and ramify, as has been seen, through the Haversian canals; in the long bones a large artery penetrates by the nutritious foramen into the medullary cavity, sending branches to the medullary cells, and inosculating with the capillaries from other sources. Nerves have not yet been detected in the interior of bones supplying strictly the osseous structure, but the painfulness of many diseases of the bones shows that the external and internal vascular surface must be supplied with nerves. Lymphatics most probably also exist in bone.—At the earliest period of the appearance of a skeleton in the embryo, it consists of a series of cells; these increase in number and density, and are held together by an intercellular substance, thus forming temporary cartilage, which is afterward converted into bone, though not completely so until adult age. Ossification commences at determinate points or centres, the first of which is in the clavicle, and appears during the fourth week; then follow the lower jaw, ribs, femur, humerus, tibia, and upper jaw; the spine and pelvis are late, and the kneecap does not begin to ossify till after birth. There are generally several ossific centres; for instance, in the long bones, one for the shaft, and one for each extremity. The central part of the bone is the *diaphysis*, and is not united till long after birth to the ends or *epiphyses*; processes of bone are called *apophyses*. Ossification generally extends in the intended direction of the chief strength of a bone. According to Todd and Bowman, the process by which cartilage is converted into bone is as follows: The small nucleated cells, with comparatively large and granular nuclei, are uniformly scattered through a homogeneous intercellular substance; at the points of ossification the cells begin to assume a linear series, running down toward the ossifying surface, and separated from one another by the intercellular substance; the cells are closely applied to one another, and so compressed that even their nu-

clei seem often to touch; the lowest rows rest in deep, narrow cups of bone, formed by the ossification of the intercellular substance; the cups are gradually converted into closed *areolæ* of bone, with their lamelliform walls. During this first stage of the process there are no blood vessels directly concerned. The lamellæ of the areolæ, or cancelli, become thicker, and include in their substance elongated oval spaces of a roughly granular nature, in other respects resembling lacunæ, and considered by these observers as the nuclei of the cells of the temporary cartilage; within the cancelli only a few cells are found, these cavities being chiefly occupied by a new granular substance, resembling a formative *blastema*, like that out of which all the tissues are evolved; the cells are in apposition with the wall, and sometimes one seems half ossified, and its nucleus about to become a lacuna; these nuclei have now the same direction as the neighboring lacunæ; from the blastema the vessels are probably developed and the necessary elements for the growth of the bone. The cancelli, at first closed cavities, communicate at a subsequent period, and go to form the Haversian systems, a network of vessels becoming developed within them at the same time. The subsequent process of ossification consists essentially in the slow repetition of the above on the entire vascular surface of the bone. The canaliculi begin as irregularities in the margin of the lacunæ, and are converted as the tissue becomes consolidated into the branching tubes which have been described above, and are accordingly formed in the ossified substance of the cartilage cells. As to the lacunæ, their granular interior seems to be gradually removed, and they become vacuities for the conveyance of the nutrient fluids. Agreeably to this theory of the formation of bone, Todd and Bowman believe that it grows chiefly by layers formed in succession on its vascular surface, but also in an interstitial manner after being originally deposited. A most important process of growth is constantly going on in cartilage by the multiplication of the cells and the increase in their dimensions; in the long bones this growth is most active in the longitudinal direction. Bones also increase by the addition of new systems of laminae on their exterior, and by new involutions of the vascular surface to form new Haversian canals, as has been proved by experiments with madder mixed with the food of animals; the coloring principle of this substance has a remarkable affinity for phosphate of lime, and it affects first the portions of bone in course of formation, or those nearest to the vascular surface. Wherever there is a vascular network in the structure of bone, whether on the periosteal or internal surface, there growth takes place; the exterior increase is strictly analogous to the exogenous mode of growth in plants. A third mode in which bone grows seems to be by the dilatation of the primary cancelli and central Haversian canals; by this enlargement

of the interior the strength of the compact exterior is increased without the disadvantage of an increase of weight.—The reparative power of bone is of the greatest importance in surgery. When a bone is broken, blood is effused, with the coagulum of which a semitransparent lymph is subsequently mingled, covering the surfaces of the wounded parts; in the course of two to three weeks this is gradually condensed by an interstitial change, which converts it into a substance resembling temporary cartilage; ossification takes place in this in a nearly uniform manner, and the whole is transformed in from four to six weeks into a spongy osseous mass which holds the ends of the bone together; this provisional *callus*, as Dupuytren called it, is gradually absorbed during the succeeding months, while the permanent callus is being deposited between the contiguous surfaces of the compact tissue; the permanent callus has all the characters of new bone. When this reparative process is interfered with by meddlesome surgery or constitutional disease, the union takes place merely by ligament, constituting sometimes a false joint.—In reptiles and fishes the cancellated structure usually extends throughout the shaft, which is not so well divided into solid bone and medullary cavity as it is in mammalia. Lacunæ are highly characteristic of true osseous structure, being never deficient in the minutest parts of the bones of the higher vertebrata, though those of fishes are occasionally destitute of them. The lacunæ of birds are longer and narrower than those of mammals, and the canaliculi are remarkably tortuous; in reptiles they are remarkably long and narrow, and in fishes very angular, with few radiations; their size is not in relation to that of the animal, since there is no perceptible difference between their size in the large extinct *iguanodon* and in the smallest living lizard. From the emarginated and festooned outline often seen on sections of bone, Dr. Carpenter, in his "Principles of Human Physiology," expresses the opinion that the older portions of the osseous substance are removed from time to time, and that the irregular outline thus presented by the Haversian spaces is caused by the partial or complete removal of the Haversian system; in their stead newly formed tissue is deposited; this alternate absorption and reproduction takes place at all times of life, though its energy diminishes with the increasing age of the individual.—The complete development of the osseous system characterizes the final stage of the growth of the organism; the vertebral column does not completely ossify in its spinous and transverse processes until the 25th or 30th year; the ossification of the head and the tubercle of the ribs, commencing soon after puberty, is not continued to the body of the bone till some years after; the ossification of some of the cartilages of the sternum is often not completed even in quite advanced age; the bones of the skull are united within a few years after birth. As long ago as Aris-

totle's time, the duration of the life of animals was measured by their period of growth. Buffon had the same idea, for he says: "The duration of life, to some extent, may be measured by the time of growth." Animals and man grow only until union takes place between the shafts and the ends of the bones; this union occurs in man at the age of 20 years, in the camel at 8, in the horse at 5, in the ox and lion at 4, in the dog at 2, in the cat at $1\frac{1}{2}$, and in the rabbit at 1 year. Recent observations go to show that animals live about five times their period of growth; this would give, according to Flourens, as the age at which man should arrive, if he lived in accordance with the laws of physiology and hygiene, about 100 years; for the camel 40, the horse 25, the ox and the lion 20, the dog 10, the cat about 8, the rabbit 5 years. In an elephant which died at the age of 80 years, the ends of the bones were not united to the shafts, so that it may be confidently asserted that this animal lives more than 150 years.

BONE, Henry, an English enamel painter, born at Truro, in Cornwall, Feb. 8, 1755, died in London in December, 1834. He was brought up to the art of painting on china, and was afterward employed in London in enamel painting on watches, lockets, and other jewelry. His remarkable skill in this work attracted special attention about the year 1800. From that time he devoted himself to painting portraits or copying celebrated pictures on ivory or in enamel. He used larger plates than had been employed for a similar purpose before; his copy of Titian's "Bacchus and Ariadne," which was sold for 2,200 guineas, is 18 inches by 16. Among his other celebrated pictures are "Hope Nursing Love," after Sir Joshua Reynolds, the "Death of Dido," and several collections of historical portraits. A series of 85 portraits of illustrious characters in the reign of Elizabeth occupied his leisure for 25 years, and was finished after his death by his son H. P. Bone. He became a member of the royal academy in 1811.

BONE ASH. Bones, when calcined in open fire, lose all their organic matters and part of the carbonic acid gas they contain, by which their weight is diminished about two thirds. The residue is a dry, friable, and white mass, of the original form of the bones. Pulverized, the powder is grayish white. It consists of basic phosphate of lime, with some lime, fluoride of calcium, carbonate and sulphate of soda, and phosphate of magnesia. The sulphur of the sulphate comes from the cartilage. Prepared from the bones of cattle, the proportion of phosphate of lime is about 90 per cent.; from human bones, about 86 per cent. Other matters may be removed by dissolving in hydrochloric acid, and precipitating by ammonia, when the phosphate of lime and a very small quantity of phosphate of magnesia alone are left in the solution. Bone ash, ground to powder, is made into a paste with gum water, or

beer and water, and moulded into the form of cups, called cupels, which are used in the process of cupellation. This is separating silver or gold from lead, by melting the alloy of the metals in the cupel, and subjecting it to the action of a current of air, which oxidizes the lead, converting it into litharge. This is absorbed by the bone ash as fast as it is produced, till the precious unoxidizable metal is at last left pure and alone in the cupel. The operation is conducted in the same manner on the large scale and in small assays. When carefully prepared, and freed from foreign matters by levigation, bone ash is called burnt hartshorn, and is used for cleaning jewelry.

BONE BLACK, a black carbonaceous powder, obtained by grinding the product of bones burned in a close vessel at a red heat. The name ivory black should properly be limited to the finer and more expensive article prepared from ivory. The volatile products of the distillation of bones are an empyreumatic oil, fetid gases, and ammoniacal vapors. The latter may be collected, as they sometimes are, in forming with them salts of ammonia. The fixed products, which constitute animal charcoal, or bone black, consist of

Carbon.....	9.6
Sulphate of lime.....	0.2
Carbonate of lime.....	8.6
Phosphate of lime.....	78.3
Phosphate of magnesia.....	1.3
Chloride of sodium.....	0.5
Silicate and sand.....	0.8
Protoxide of iron.....	0.2
Alkalies, and sulphur.....	0.5

100.0

The powder resembles that of vegetable charcoal, but is more dense and less combustible, and its ashes are not so readily soluble in sulphuric acid as those of charcoal. The process of preparing the material varies according as the ammoniacal vapors are saved, or allowed to go to waste. In the former case the bones, cleaned of their fatty matters, are carbonized in cast-iron cylinders, which connect by a three-inch pipe with the condensing apparatus. The cylinders are kept at a red heat for 36 hours, when the charred bones are taken out, and the cylinders are refilled. The bones are then ground in mills. The volatile products are in some instances discharged under the fire, by which they are consumed, and their disagreeable odor destroyed. In this way also they afford some heat, and save fuel. By the other process, the bones are put in cast-iron pots, which contain each about 25 lbs., and these are put together in pairs, mouth to mouth, and luted. They are then piled up in an oven or kiln, the entrances to which are tightly bricked up, except those for the admission of the flame from the furnace connected with the kiln, and the opening into the chimney. The pots are well heated for 16 to 18 hours by the flame playing around them, and this is increased by the combustible vapors which issue from the bones. Other arrange-

ments have been contrived for consuming the disagreeable gases.—The valuable property possessed by bone black is its absorbing completely the color of organic solutions, and leaving the liquid clear and limpid; this is greatly facilitated by heating the mixture to the boiling point. Vegetable charcoal possesses the same property also, but to a much less degree. From the year 1800 wood coal continued to be used for decolorizing crude sirups, for which purpose it was about this time recommended by Löwitz, a chemist of St. Petersburg; but in 1811 M. Figuier of Montpellier discovered the greater efficiency of animal charcoal for this purpose, and this being employed the next year by Derosne and Payen, it has since superseded the use of vegetable coal. Although this property of charcoal has been ably investigated by distinguished chemists, as Bussy, Payen, and Derosne, it does not yet clearly appear upon what it is dependent, nor whether it acts mechanically or chemically. M. Bussy has shown that bone black used for decoloring an indigo solution in concentrated sulphuric acid, and this diluted with water, does not give the slightest trace of sulphate of indigo by repeated washings, but does of free sulphuric acid. Treated, however, with an alkaline wash, the charcoal gives up the indigo, thus appearing as if it acted mechanically. The efficiency of the charcoal is greatly dependent upon its being in a minute state of division. The earthy matters combined with the carbon of bones, no doubt, have great influence in effecting this condition. Vegetable coal attains it to some extent, and the decolorizing property also, by being finely comminuted previous to charring, and mixed with pulverized pumice, quartz, or calcined bones, or with some chemically acting ingredient, as carbonate of potassa. The most powerful decolorizer is charcoal obtained in the manufacture of Prussian blue by calcining animal matter with potassa. It is the purest form of charcoal, freed by the potassa from its nitrogen, and reduced by chemical segregation to the finest particles. Carbon obtained by decomposing carbonate of soda also possesses this property in a high degree, from the fine state of division in which its particles are found, so that it would appear to be by no means peculiar to animal charcoal. Even other substances than carbon are observed to possess the same property, as has been shown by E. Filhol, such as sulphur, arsenic, iron reduced by hydrogen, &c. Bone black that has been once used for refining sirups may be revived, so as to answer the same purpose again. The process consists in thoroughly washing out the saccharine matters absorbed, and in some establishments in dissolving the lime, which is also taken up by the bone black, by fermentation in water acidulated with hydrochloric acid. The charcoal is then again calcined in crucibles, or, as in France, in reverberatory furnaces. High steam is said also to restore its property, but this

cannot remove the lime. Several forms of furnace have been contrived in England to effect this purpose; and retorts are used which hold 50 lbs. of charcoal, and in which the re-burning is completed in 15 or 20 minutes.—Besides extracting the color of fluids, animal charcoal takes away the bitter principle from bitter infusions, and iodine also from its solutions; and it is found by Graham that various inorganic substances are abstracted from their solutions, as lime from lime water, and metallic oxides, as lead, from solution in water. Bone black is also used to extract from spirits distilled from grain the volatile poisonous oil, called fusel oil, which gives to the liquors a disagreeable taste. It is also a disinfecting agent.—For chemical and pharmaceutical purposes, bone black requires to be purified, that is, freed from the phosphate and carbonate of lime which constitute its principal part. Dilute hydrochloric acid is used to dissolve these out, and the residue, being well washed, is pure animal carbon. It is used to absorb the active principles of plants from their boiling infusions. The charcoal, after being well washed and dried, is mixed with boiling alcohol, to which it imparts the principle it has absorbed from the vegetable infusion, and an alcoholic extract is obtained. The alcohol then may be distilled off, and the pure substance recovered. Quinia, strychnia, and many other vegetable principles, are thus procured.—The refuse animal black of the sugar refiner is largely used as a manure, and in the manufacture of phosphorus and of baking powders. From the investigations of M. A. de Romanet, it appears that, in old soils exhausted of humus, it produces no effect, having none of this substance to restore to the soil. But it gives out the ammonia it had taken up in the sirups, and neutralizes the bitter and acid principles of healthy or new soils; the phosphates it contains are also rendered soluble in water, and are thus furnished to grains requiring them.

BONE CAVES. In many natural excavations, both in the old and the new world, mostly in the secondary limestone strata, the result of fracture of the earth's crust, of chemical action of acid waters, of erosion by powerful currents, and of slow disintegration by the elements, have been found the bones of extinct post-tertiary mammals, mingled sometimes with the works and bones of man. The most celebrated of these caves in Europe are near Kirkdale, England, 25 m. N. E. of York, fully explored by Dr. Buckland; at Bristol; Kent's cave, near Torquay; in the valley of the Dordogne, France, especially those of Moustier and Cro-Magnon, described by Christy and Lartet; and at Gailenreuth in Bavaria. There are many others in Belgium, near Liège; in Sicily, at Gibraltar, in Mexico, in several parts of the United States, and in Brazil. These caves may consist of several chambers at different levels, and show on their walls the erosive action of water, and at the bottom and top various de-

posits of stalagmite and stalactite from the infiltration of lime-bearing waters. Under this lime floor ancient bones have been discovered, mingled, both as to size and species, in the most indiscriminate manner; they are often rolled, as if from the action of floods, sometimes fissured, but often unchanged. The bones most abundantly found are those of the great carnivora of the quaternary period, the bear, hyæna, lion, &c.; with those of the great pachyderms, as the mammoth and the rhinoceros; and of many herbivora and rodents. The English caves were mostly occupied by hyænas, while those of the continent were chiefly caves of bears. At Kirkdale Dr. Buckland found the remains of at least 75 hyænas, of the extinct or cave species, mixed with those of the extinct pachyderms, carnivora, ruminants, and rodents; from which he believed that the hyænas dragged the carcasses there and fed upon them, cracking their bones with the marks of their teeth peculiar to this animal, and leaving behind them their fossil fæces. In Gailenreuth have been found the bones of the cave bear, of at least 800 individuals. Caves containing bones of post-tertiary mammals are rare in North America; but in those of Brazil, explored by Dr. Lund, remains of gigantic rodents, pachyderms, and edentates were found, especially of the extinct megatherioids. The bones found in the caverns have a uniform appearance over large areas of country, and evidently belong to the geological period intermediate between the tertiary and the present epochs. Though some of these caves owe their remains to the fact that they were the dens of hyænas and bears, or were the retreats of sick and wounded animals, there can be no doubt that most of their contents have been brought to the caves by temporary torrents of water independent of marine action; the bones could not have come from a great distance, as they belong to the then existing animals of the region, and are the same as those met with in external transported sediments. Remains of man and of his works have been found mingled with the bones of the above post-tertiary extinct mammals in the caves of Europe, and especially of southern France by Messrs. Christy and Lartet, seeming to place it beyond doubt that man began his existence at this remote epoch. The implements found are invariably those of the early stone age, and the bones never those of the domestic animals afterward subjugated by man.—See *ARCHÆOLOGY*, and the works of Dr. Buckland, Constant-Prévost, Lyell, and the *Reliquiæ Aquitanicæ* of Christy and Lartet.

BONE DUST, bones crushed and ground to dust for manure. The finer the dust the more rapid is its action; the coarser the particles, the longer is their effect slowly given out. This substance is beneficial to the growth of plants from its affording them several of the constituents they require. The following analysis of dry ox bones is by Berzelius:

Phosphate of lime, with a little fluoride of calcium	57-85
Bone gelatine	88-90
Carbonate of lime	8-85
Phosphate of magnesia	2-05
Soda, and a little chloride of sodium	8-45

100-00

The phosphate of lime of the solid bone, and the ammonia furnished by the organic matters connected with it, are particularly beneficial. So valuable is this substance regarded as a manure in England, that in the report of the Doncaster agricultural association it is stated that one wagon load of small drill bone dust is equal to 40 or 50 loads of fold manure. Upon thin and sandy land it is particularly effective, and continues to act for several successive crops. It is best applied when mixed with earth and fermented, and at the rate of 25 bushels of fine bone dust and 40 of broken bones to the acre. It is also used as a top dressing, sown broadcast and by the drill. Pasture and grass lands are greatly benefited by it; white clover springs up wherever it falls; and the turnip crop is largely increased by its application. Bone dust is sometimes adulterated with the raspings and filings of the ivory nut.—In this place the use of dissolved bones and other phosphates, first recommended by Liebig in 1840, may be noticed. The phosphatic materials are first ground to a very fine powder by millstones; the powder is then carried up by means of elevators and discharged continuously into a long iron cylinder, having agitators revolving within it with great velocity. A constant stream of sulphuric acid, sp. gr. 1.66, enters the cylinder at the same end as the dry powder, and the mixture flows out at the other end in the form of thick mud, having taken three to five minutes in passing through the machine. The quantity turned out by such a mixing machine is about 100 tons daily. The semi-fluid mass runs into covered pits 10 to 12 feet deep, each of sufficient size to hold the produce of the day's work. It becomes tolerably solid in a few hours, but retains a high temperature for weeks, and even months, if left undisturbed. The composition of a superphosphate of good quality, made partly from mineral phosphate and partly from ordinary bone, may be stated as follows:

Soluble phosphate	22 to 25 per cent.
Insoluble phosphate	8 to 10 "
Water	16 to 12 "
Sulphate of lime	35 to 45 "
Organic matter	12 to 15 "
Nitrogen	0.75 to 1.5 "

If sufficient sulphuric acid were used to decompose the whole of the phosphate of lime, the product would be too wet to be packed in bags, and would require either to be mixed with extraneous substances of a dry and porous nature or to be artificially dried. The manufacture of manures from guano, from the Ashley river deposits of South Carolina (see COPROLITES), and from the mineral apatite, has become an industry of great importance. The commercial superphosphates are so frequently

adulterated that purchasers would do well to have the samples analyzed before contracting for large quantities.

BONESET, or *Thoroughwort*, the herb *eupatorium perfoliatum*, an indigenous perennial plant growing in moist places, distinguished by the perfoliate character of its leaves, each pair of which are at right angles to those immediately above and below. It is a bitter weed or vegetable tonic, with a faint odor and a strong bitter taste. Hot water extracts its virtues, which are believed to reside chiefly in a bitter principle. The cold infusion acts as a mild, pleasant tonic; the hot infusion as a diaphoretic, and, when very strong, as an emetic. Strong infusions of boneset leaves are used as a substitute for Peruvian bark in cases of ague, and sometimes with success; but it is not always to be relied on. A pint of boiling water is poured upon an ounce of the dried leaves, or

Boneset.

a pint of cold water upon an ounce of the fresh leaves, and allowed to stand two hours; it is then strained for use. A weak cold infusion is good for all cases of debility where tonics are prescribed. For ague as much should be taken as the stomach will bear, and it should be drunk warm.

BONET, Juan Pablo, a Spanish instructor of the deaf and dumb, held by some authors to have been the inventor of their first alphabet and means of communication, born in Aragón in the latter part of the 16th century. He was attached to the secret service of Philip III., but the greater part of his time was occupied by his efforts in behalf of the class in which he had become interested early in life. His system is explained in his work on the subject, *Reduccion de las letras y artes para enseñar á hablar á los mudos* (Madrid, 1620). His claim to the actual invention of the first means of communication for the deaf and dumb is rejected by the majority of writers, who give the credit to a Spanish Benedictine monk, Pedro Ponce, who lived some 50 years before Bonet. Ponce wrote nothing of the art, however, and

the honor of first diffusing this important knowledge seems to belong entirely to the latter teacher.

BONHEUR. I. Rosalie (commonly called ROSA), a French painter, born at Bordeaux, March 22, 1822. Her first instructor in painting was her father, Raymond Bonheur, an artist of considerable merit; but she owes her remarkable success in the delineation of animals to a constant study of living subjects. Her first contribution to the French exhibition was made in 1841, when she sent two pictures, "Goats and Sheep" and "Two Rabbits." From that time she devoted herself to her favorite class of subjects, visiting stables, shambles, and fairs, and studying the structure and habits of animals under all circumstances. The result of these studies was a series of pictures which gave her a reputation second to that of no artist in her special department. Among the most noted of her paintings are "The Horse for Sale," "Horses in a Meadow," "The Three Musketeers," "A Drove on the Road," "Farm Labor in Nivernais," "Cows and Sheep in a Hollow Road," "The Horse Fair," "Deer Crossing an Open Space," and "Bucks in Repose." The "Ploughing in Nivernais" was placed in the Luxembourg, and the "Horse Fair" was a leading attraction at the exposition of 1853. The artist worked 18 months on this latter picture, attending the horse market in Paris regularly twice a week during the time. To the universal exposition of 1867 she sent ten pictures. Mlle. Bonheur became directress of the free school of design for girls at Paris in 1849, but has given little of her own time to its affairs, her sister Mme. Peyrol having actual charge of the institution. She has tried her hand at sculpture as well as painting, and in 1848 took a first class medal for a bronze group. She has received several other medals and prizes, and in 1865 was decorated with the cross of the legion of honor. Her latest picture (1872) represents a fight between a hyæna and a tiger. **II. Auguste**, a French artist, brother of the preceding, born in Bordeaux, Nov. 4, 1824. He studied under his father, and has painted landscape, genre, and cattle pieces, making rather a specialty of the last named department, besides a few portraits. He has received a medal of the first class. **III. Jules Isidore**, a French sculptor, brother of the preceding, born in Bordeaux, May 15, 1827. He studied painting under his father, and at the same time gave much attention to modelling in clay, choosing animals generally for his subjects. His first works publicly exhibited were a painting representing a combat between a lioness and a horseman, and a sculptured group illustrating the same subject. He soon after abandoned painting, and has since devoted himself exclusively to the production of single figures and groups, mostly in bronze, representing cattle, horses, dogs, and animals of the chase. **IV. Juliette** (Madame Peyrol), a French painter, sister of the pre-

ceding, born in Paris, July 19, 1830. She has painted chiefly animals and rural subjects, and is her sister's chief assistant in the direction of the school of design for women at Paris.

BONHOMME, a S. E. county of Dakota, separated from Nebraska on the south by the Missouri river; area, about 400 sq. m.; pop. in 1870, 608. The productions in 1870 were 1,930 bushels of wheat, 3,520 of Indian corn, 1,590 of oats, 2,870 of potatoes, and 1,315 tons of hay.

BONI, one of the principal states of the Bughis nation in the S. W. peninsula of Celebes, bounded E. by the gulf of Boni and W. by Macassar; area, 2,850 sq. m.; pop. 180,000. The country is mountainous, Lompo-Batang (great pillar), 8,200 ft. high, being the loftiest peak on the island. Lake Labaya, in the N. W. corner of the territory, is a beautiful sheet of water, 24 m. long by 13 broad, and receives numerous small streams. The valleys and plains are fertile, and inhabited by a thrifty and industrious people. They carry on considerable traffic in gold dust, tortoise shell, pearl, camphor, nutmegs, and various drugs, and obtain European products from Batavia and Singapore. The country is tributary to the Netherlands, but is governed by a king who is chosen for life by the chiefs of the eight petty states of which it is composed, and who can decide upon no important measure without their consent. The capital is the inconsiderable town of Boni, on the shores of the gulf, in lat. 4° 22' S., lon. 120° 18' E.

BONIFACE, the name of nine popes of the Roman Catholic church. **I. Saint**, the successor of Pope Zosimus in 418, died in 422. The emperor Honorius supported his claims to the pontifical chair against the archdeacon Eulalius, who was chosen by an opposition party supported by Symmachus. St. Augustine dedicated to this pontiff his four books against the Pelagians. **II. Successor of Felix IV.** in 530, died in 532. His election was disputed, but Dioscorus, the rival claimant, died, and the schism ended. **III. A Greek**, successor of Sabinianus in March, 607, died in November of the same year. He convoked a council of 72 bishops, in which certain laws were passed against choosing successors to popes or bishops during their lifetime, and obtained from the emperor Phocas the acknowledgment that the see of Rome had universal supremacy. **IV. Saint**, son of a physician, successor of Boniface III., died probably in 615. He changed the Pantheon with the permission of the Byzantine emperor into a church, and his own house in the country of the Marsi into a monastery. **V. A Neapolitan**, successor of Pope Deusdedit in 619, died in 624 or 625. He forbade civil judges to take away from the churches by force those who claimed there the right of asylum. **VI. Pope** after Formosus in 896, occupied the throne only 15 days. Having been uncanonically elected by a popular faction, he is sometimes regarded as one of the antipopes. **VII. Franco**, a cardinal deacon,

chosen in a popular tumult in which Benedict VI. was strangled in 974, died in 985. He was expelled from Rome shortly after his election, and went to Constantinople, but returned on the death of Benedict VII. (983), and finding John XIV. in the papal chair, had him thrown into prison and resumed the place. **VIII. Benedetto Gaetano**, born at Anagni about 1228, died in Rome in October, 1303. About 1255 he visited England; in 1280 he went to Germany as secretary of a papal legate; in 1281 he was made a cardinal by Martin IV., who allowed him to receive the revenues of twelve benefices, seven of them being in France and one in England. He was papal legate in France in 1290, and afterward in Sicily and Portugal, and was chosen to the papal chair on the abdication of Celestine V. in December, 1294. His entry into Rome was attended with extraordinary pomp. In 1296 Boniface issued his famous bull, *Clericis laicos*, by which he forbade the clergy, under pain of excommunication, to pay without the consent of the holy see any subsidy or tax on any ecclesiastical property, and extended the excommunication to the emperors, kings, or princes who should impose such subsidy. The vigor with which Philip the Fair resisted this bull obliged the pope to retract, and to allow the taxes to be raised in France as before. He became soon after embroiled with the Colonna family, who denied the validity of his election. Two cardinals of this family were deprived of their dignities; the entire family were excommunicated, their descendants were condemned to civil degradation to the fourth generation, their castles and their city, Præneste, were totally destroyed, and Frederick of Aragon, whom they had supported, was ordered to renounce the title of king of Sicily, and to evacuate the island. The Colonnas took refuge in France. Boniface interfered to make peace between France and England. He censured the king of Denmark and his brother; forbade the king of Naples to treat with Frederick, elected king of Sicily; summoned to Rome Albert I., king of Germany, whose election as emperor he declared to be invalid without the papal sanction; and rebuked Philip the Fair for his treatment of Guido of Flanders. In 1300 Boniface proclaimed the first jubilee in a bull granting plenary indulgence to all who should visit the sanctuaries in Rome during that year. Soon after this his quarrel with the king of France became more violent than ever. In December, 1301, Boniface issued the bull *Ausculta Dei*, and convoked a council of the French bishops at Rome to examine the conduct of King Philip, at the same time affirming it to be heretical not to believe that the king was subject to the pope in secular as well as spiritual affairs. The French nation, however, opposed the pretensions of the pope, and supported their king; and it was formally declared by the three estates that the king held his power in fief to no one, and in secular matters was

subject to God alone. The bishops were forbidden to attend the council at Rome, which therefore was never held. In 1302 the bull *Unam sanctam* affirmed the claims of the pope, setting forth that the church wields two swords, the spiritual and the secular, but that the secular is subordinate to the spiritual, and that therefore kings, who hold the former, are subject to the pope, who holds the latter. The bishops of France were again convoked under pain of excommunication; but Philip ordered the sequestration of the property of every one who should be absent from his diocese, and in his turn summoned a general council at Lyons to judge the pope. To this council the university of Paris and a large number of prelates adhered; the excommunication of Philip followed, April 18, 1303; and in June the assembled estates of France declared the pope a criminal and a heretic. The king sent Guillaume de Nogaret and Sciarra Colonna to Rome to seize the pope and bring him before the council of Lyons. They armed about 300 malcontent Italian nobles, surprised Anagni, the residence of Boniface, forced the palace, and seized the person, diamonds, and papers of the pope, and guarded him as a prisoner. After three days Boniface was rescued by the inhabitants of Anagni and taken to Rome, where he was protected in the Vatican by the Orsini; but the violent commotion he had gone through caused his death 34 days after his captivity. Boniface incurred the bitter enmity of Dante by his persecution of the Ghibellines, and is repeatedly denounced in the *Divina Commedia*. **IX. Pietro Tomacelli**, born in Naples, succeeded Urban VI., at Rome, Nov. 2, 1389, while the antipope Clement VII. ruled at Avignon, died in Rome, Oct. 1, 1404. He recognized Ladislas, the son of Charles of Durazzo, as king of Naples in 1390, and celebrated two jubilees, 1390 and 1400. The annates, which had before been occasional, he made perpetual, and decreed that archbishops and bishops nominated to benefices should pay to Rome one half of their first year's revenue. He was twice expelled from Rome by the municipal authorities, and when in 1400 his presence became necessary for the celebration of the jubilee, he refused to return till the Romans consented to the overthrow of the municipal government, promised obedience to a senate appointed by himself, and paid him a sum of money. From that time he ruled the city absolutely.

BONIFACE, a saint of the Roman Catholic church, born in Devonshire, England, about 680, died in Friesland in June, 755. His baptismal name was Winifrid or Winifreth. He is usually called the apostle of Germany, though he was not the first to preach Christianity in that country. He was educated in the Benedictine monastery of Exeter, and was at one time professor of theology, history, and rhetoric in that of Nuteoll, where he became a presbyter. In 718 he went to Rome, and received from

Pope Gregory II. an apostolic mission to Germany. He entered Friesland, where he preached during three years, then passed into Hesse, and founded there a monastery, around which in the course of time grew up the city of Marburg, and which now remains as a university. In 723 Gregory II. called him to Rome and consecrated him as a bishop, and on this occasion his name of Winifrid was changed to Boniface. In 732 Gregory III. made him archbishop and primate of Germany, and in 738, after a third journey to Rome, papal legate. He erected various bishoprics, and established numerous churches in different parts of the country. He also exercised a great influence over the last Merovingians, and over Pepin and Carloman. He was named archbishop of Mentz by Pepin, and founded the celebrated abbey of Fulda, and also those of Fritzlar and Hammelburg. Boniface finally gave up his see of Mentz, in order the better to preach to the Frisians. In one of his journeys across the savage country where now is Dokkum, near Leeuwarden, he was attacked by the natives and slain, together with some 50 of his converted companions, whom he forbade to use any means of defence. His body was buried in Utrecht, afterward removed to Mentz, and finally to Fulda, where a copy of the Gospels in his handwriting is still preserved. A complete edition of his letters was published at Mentz in 1789. His other writings (*De Rebus Ecclesiasticis*, *Instituta Synodalia*, and *De suis in Germania Rebus*) were published at Oxford in 1845, in 2 vols. A monument to him was erected in 1811 on the spot (near Altenberga, Thuringia) where the first Christian church was built by him in 724. Another was erected at Fulda in 1842.

BONIFACIO, Strait of (It. *Bocca di Bonifacio*), the passage between Corsica and Sardinia, about 7 m. wide in the narrowest part. The land is mountainous and the shores steep on either hand. Several small islands lie at the eastern entrance. The strait is difficult of navigation. The town of Bonifacio, an ancient seaport on the southern extremity of Corsica (pop. about 3,000), has important coral fisheries. A submarine telegraph connects it with Longo Sardo on the opposite Sardinian coast.

BONIN. I. **Eduard Wilhelm Ludwig von**, a Prussian general, born at Stolpe, March 3, 1793, died in Coblenz, March 18, 1865. He was the son of a general, and enlisted in his 18th year; captured by the French at the taking of Lübeck, Nov. 6, 1806, he was immediately released on account of his youth. He was rewarded with the iron cross for his gallantry at the battle of Lützen, gradually rose in rank from 1817 to 1848, when he became brigadier general, and acquired celebrity in the first Schleswig-Holstein war. In 1849 he was commander-in-chief of the federal as well as of the Schleswig-Holstein troops. He relinquished these commands in 1850, was Prussian minister of war in 1852-'4, and again in 1858-'9, and

spent the rest of his life in Coblenz as commanding general of the eighth army corps. **II. Adolf von**, a Prussian soldier, born Nov. 11, 1803, died in Berlin, April 16, 1872. He entered the army in 1821, became in 1858 adjutant general of the king, which post he retained till 1863, when he rose to the command of the first army corps, and in 1864 to the rank of general of infantry. He distinguished himself at the battle of Sadowa, July 3, 1866, and subsequently acted as commander of the Prussian forces in Saxony, and as governor of Dresden till May 28, 1867. In August, 1870, he was appointed governor general of Lorraine, where he displayed tact and moderation. In March, 1871, he resumed his position on the royal staff.

BONIN ISLANDS, a group of 70 islands and 19 rocks in the north Pacific, composed of three small clusters, between lat. 26° 30' and 27° 44' N. and lon. 142° and 145° E. The northern cluster was named by Capt. Beechey Parry's group, and the southern, Baily's group, while

Chasm near Port Lloyd.

to the islands of the middle cluster he gave the separate names of Peel, Buckland, and Stapleton. Peel island (the only one inhabited) has long been visited by whalers for supplies. From 1675 to 1725 the Bonin islands were used by the Japanese as penal colonies. In 1826 the first settlement was made by two English sailors, and in the same year Capt. Beechey arrived to take possession of the islands for the British crown. By the treaty of 1854, Port Lloyd on Peel island was opened to American and British shipping. The Bonin islands are volcanic; the water around them is very deep, and the shores are precipitous and abound in singular chasms, one of the most remarkable of which is through a headland near Port Lloyd. Timber is scarce. The few inhabitants, chiefly natives of the Sandwich islands, adopted a constitution, Aug. 28, 1853, and are ruled by a magistrate who is elected for two years.

BONINGTON, **Richard Parkes**, an English painter, born at Arnold, near Nottingham, Oct. 25, 1801, died in London, Sept. 23, 1828. He was the son of an artist, and was educated in Paris. Having achieved some reputation there he went to Venice, where he made many sketches, and

in 1828 returned to England. He painted chiefly in water colors, reviving the taste for them in France, after they had been neglected for 20 years. His best productions are marine views and representations of coast scenery.

BONITO, a name given to several scomberoid fishes of the genera *thynnus*, *auxis*, and *pelamys*. The bonito of the tropics, so celebrated for its pursuit of the flying fish, is the *thynnus pelamys* (Linn.). Its range is exten-

Bonito (*Thynnus pelamys*).

sive in the tropical Atlantic, and it probably extends to the Pacific and Indian oceans. It has the graceful form, habits, and activity of the common tunny, but it is much smaller, rarely attaining a greater length than 2½ ft.; the color of the back and sides is of a brilliant steel blue, with green and pink reflections; the belly is silvery, with eight brown longitudinal bands, four on each side, extending from the throat to the tail. Its food is principally small fish, the higher mollusks, and sometimes marine plants; it is readily taken by the hook, and its flesh,

Plain Bonito (*Auxis vulgaris*).

though dry and occasionally injurious, is considered by mariners as a luxury. The *T. coretta* (Cuv.) is also called bonito in the West Indies. The bonito of the Mediterranean is the *auxis vulgaris* (Cuv.), resembling the mackerel in the separation of the dorsal fins; the color of the back is blue, with irregular lines and spots of a blackish blue on the sides; the average length is 15 inches, and the weight rarely exceeds 6 lbs. The bonito of the New England

fishermen is the *pelamys sarda* (Bloch), called also skipjack; its genus differs from the tunny only in having separate, pointed, and strong teeth; the color of the head and upper parts is a greenish brown, the sides lighter, and the belly silvery white; 10 or 12 dark-colored bands pass obliquely downward and forward from the back toward the sides, sometimes as low as the abdomen; the lateral line is rather undulating; it is rarely more than 2 ft. long. It is found in the Mediterranean, and in the temperate regions of the Atlantic, from the Cape Verd islands to the American coast; it is considered good eating in the Mediterranean. The *P. Chiliensis* (Cuv.) of the Pacific coast of South America is also called bonito. This term is Spanish, meaning "pretty," and is doubtless applied to many other species of fish.

BONJOUR, two brothers, natives of Pont d'Ain, in France, who founded a new sect somewhat similar to the Flagellants of the 13th century. They were educated for the church, and the elder held at first a curacy in La Forez. In 1775, being censured by his bishop for heresy, he was removed from this parish and appointed to that of Fareins, of which his brother was made vicar. After living an irreproachable life for eight years, the elder brother resigned the curacy to the younger, alleging himself to be unworthy of the office. He soon acquired a reputation for working miracles, and attached to himself a number of followers, mostly women and young girls, who called him their *petit papa*. They held to community of goods, and indulged in eccentric practices which excited a very strong popular sentiment against them. One of the devotees, a young girl, was said to have been publicly crucified by Bonjour in the church, without sustaining any injury. One of their most prominent opponents being found dead in his bed, by the prick of a needle, the elder Bonjour was exiled, and his brother imprisoned in the convent of Toulay, from which he escaped, as he alleged, by the intervention of an angel. The revolution of 1789 encouraged the former to return to Fareins, and in the absence of the curé and vicar he took possession of his church, and issued orders to his followers, who rallied around him. He was, however, soon dislodged from his occupancy, and under the consulate exiled to Lausanne with his brother, where they both died in extreme poverty. Their sect, known as the *flagellants fareinistes*, perished with them.

BONN, a city of Rhenish Prussia, on the left bank of the Rhine, 15 m. S. S. E. of Cologne; pop. in 1871, 26,020, of whom about 4,300 were Protestants, 500 Jews, and the rest Roman Catholics. It is finely situated on an eminence in a fertile region, 10 m. N. N. W. of the peak of Drachenfels. It has seven gates, and with its many gardens presents a cheerful appearance. The finest public square, Münsterplatz, adjoining the cathedral, is planted with trees, and has a monument of Beethoven, who was born at Bonn. The bust of Arndt was

placed in 1865 on the beautiful promenade of the Alte Zoll, and his house and garden have been presented to the town for conversion into a turners' hall. Bunsen died here in 1860. The monument of Niebuhr, by Rauch, is in the cemetery outside the Sternen gate. A. W. von Schlegel and Schumann were also buried here. The cathedral or minster, surmounted by five towers, contains a bronze statue of St. Helena, the mother of Constantine the Great, and supposed founder of the church. The central tower, the windows of the nave, and the cloisters are its most remarkable parts. The church of St. Remigius contains a picture by Spielberg of the baptism of Clovis. A Protestant church has been established since 1864. The town hall, on the market place, is a handsome modern building; but the most renowned public edifice is the university, the chief source of the celebrity and prosperity of Bonn, and the most elegant and extensive academical building of Germany. It was formerly an electoral pal-

provided by him with the present palace. There are five faculties, namely, of Protestant and Roman Catholic theology, medicine, jurisprudence, and philosophy; the teachers include about 90 professors and adjuncts, and the number of students is nearly 900. Prince Albert and his son Prince Alfred studied here, and among the professors have been some of the most learned men of Germany.—Bonn occupies the site of the ancient Bonna, a town of the Ubii, afterward a Roman stronghold, included in Germania Secunda. According to Tacitus, Civilis here defeated the Roman troops under Gallus. Bonn is said to have embraced Christianity in the year 88. It was destroyed in 355 by German tribes, and rebuilt in 359 by Julian; and it was again almost ruined by the Northmen in 881. The archbishop of Cologne surrounded the town with walls in 1240, and conferred many privileges upon it; and the emperor Charles IV. was crowned here in 1346. The French took it in 1673,

University of Bonn.

ace, and contains a hall decorated with frescoes, lecture rooms, a library with over 200,000 volumes, a museum of Rhenish antiquities, a cabinet of natural history, and an archaeological museum. There are separate buildings for the anatomical theatre and chemical laboratory. The villa of Poppelsdorf, formerly an electoral chateau, a mile from the town, belongs to the university, and contains apartments for the officers and professors, lecture rooms, galleries of painting, and a collection of natural history. Here are situated the botanical gardens, an agricultural institute with an area of over 100 acres, and a manufactory of earthenware and pottery. On the fine road to Poppelsdorf is the observatory. The university was founded in 1786 by the archbishop Maximilian Frederick. In 1802 it was converted by the French into a lyceum, but restored upon a much larger scale in 1818 by Frederick William III., and

surrendered it to the prince of Orange and Montecuculi in the same year, regained possession in 1688, and lost it in 1689, when it was bombarded and captured by Frederick III., elector of Brandenburg. In 1703 it was taken by Coehorn after three days' bombardment, and most of the fortifications were razed in 1717. It was under French domination from 1801 to 1814, when it was made part of Prussia.

BONNER, Edmund, an English bishop, born at Hanley, Worcestershire, about 1495, died in the Marshalsea pris-

on, London, Sept. 5, 1569. His reputed father was a sawyer, but some affirm that he was the illegitimate son of a priest. In 1512 he entered Pembroke college, Oxford, where in 1519 he took the degrees of bachelor of the canon and civil laws, and was soon after ordained. By 1525 he had attained the degree of doctor, and was appointed chaplain to Wolsey. After the fall of Wolsey he became a favorite of Henry VIII., and received several livings. Much of his promotion was due to the favor of Thomas Cromwell, into whose schemes for religious reformation he warmly entered. In 1532 he was sent as envoy to Rome, and the next year to Marseilles, where Pope Clement VII. then was, to appeal to a general council from the papal decree of excommunication against Henry VIII. on account of his divorce from Catharine of Aragon. In 1538, while on an embassy to Paris, he was

named bishop of Hereford, but before his consecration was translated to the see of London; his commission from the king was dated in 1540. In 1547 he was sent as ambassador to the emperor Charles V. After the death of Henry, Bonner broke with the reformers, and, protesting against the measures of Cranmer, hesitated to take the oath of supremacy; for this he was committed to the Fleet, but making submission was soon released. His continued hostility to the reformation drew upon him the displeasure of the privy council, before whom he was arraigned on charge of failing to fully comply with an order directing him to preach a sermon on the contested four points. For this, in October, 1549, he was deprived of his bishopric, and committed to the Marshalsea prison. Upon the accession of Queen Mary, in 1553, he was restored to his see, and became a prominent upholder of the persecutions which followed. He was appointed to perform the act of degradation upon Cranmer, against whom he had an old grudge, and executed this function with extreme insolence. The names of 125 persons are given who were executed for heresy in his diocese, and through his agency; and 22 more whom he had condemned were saved only through the influence of Cardinal Pole. When Elizabeth ascended the throne in 1558, she manifested a strong repugnance to Bonner, but left him in possession of his see until the next year, when, upon his refusing to take the oath of supremacy, he was deposed, and again committed to the Marshalsea prison, where he remained until his death. Even after ten years' confinement public feeling was still so bitter against him that he was buried at midnight for fear of a tumult.

BONNER, Robert, an American journalist, born near Londonderry, Ireland, April 28, 1824. In 1839 he came to Hartford, Conn., where his uncle was a prosperous farmer, and entered the printing office of the Hartford "Courant" as an apprentice. Here he became a thorough printer, and laid the foundation of his subsequent fortune by extra work and rigid economy. He removed to New York in 1844, was employed upon the "Evening Mirror," and acted as correspondent of the Hartford "Courant," and of newspapers in Boston, Albany, and Washington. In 1851 he founded the "New York Ledger," by purchasing the business and establishment of the "Merchant's Ledger," a weekly commercial newspaper, which he transformed into a journal of current literature and popular fiction. His enterprise in the conduct of this paper, and especially his practice of advertising to an unprecedented extent, has given it an immense circulation, at times reaching 400,000 copies. Mr. Bonner is well known as the owner of the finest stable of trotting horses in the United States, which he never allows to take part in public races.

BONNET, Charles, a Swiss naturalist and philosopher, born in Geneva, March 18, 1720, died there, May 20, 1793. He was educated for the

law, but reading Pluche's account of the *formica leo*, he undertook to find this insect for himself. This search interested him in many other insects. He read other works, and made further observations, discovering several undescribed species, and becoming a naturalist of rare attainments at the age of 16. At 18 he communicated to Réaumur several interesting facts, and at 20 his discovery that several generations of aphides are produced by a viviparous succession of females without the males, for which he was elected a corresponding member of the French academy of sciences. Learning of Trembley's experiments on the reproduction of certain polyps by bisection, Bonnet experimented, and discovered that certain so-called worms could be multiplied by the same process. He published these discoveries in his *Traité d'insectologie* (1745). In 1754 he published *De l'usage des feuilles*, treating upon vegetable physiology, and in 1762-'8 *Considérations sur les corps organisés*, embodying his views on the origin and reproduction of organic forms of life. The failure of his sight drove him from the field of actual observation to that of speculative philosophy. His *Essai de psychologie* appeared in 1754, and his *Essai analytique des facultés de l'âme* in 1760. In his *Contemplation de la nature* (1764-'5) he tried to construct a chain of nature from the lowest organism up to the Deity. His *Palingénésie philosophique* (1770) puts forth the idea that the souls of animals are immortal and rise progressively in the scale of being. He published in 1771 *Recherches philosophiques sur les preuves du Christianisme*, a defence of revelation. His complete works were published at Neuchâtel, before his death, in 8 vols. 4to, and with illustrations, in 18 vols. 12mo.

BONNEVAL, Claude Alexandre, count de, a French soldier, born at Coussac, in Limousin, July 14, 1675, died in March, 1747. Being found unmanageable at the Jesuit college, he left it to enter the navy at the age of 12 years. He left this service in 1698 on account of a duel with the lieutenant of his vessel, and bought a commission in the guards, and afterward in a regiment of infantry. He served with Vendôme in Italy, where he displayed great courage and skill. Getting into trouble with the accounting officers and the minister of war, he wrote the latter an insulting letter and threw up his commission as colonel. After spending some time in Italy, he entered the service of Austria as a major general, and fought under Prince Eugene in several campaigns in Italy, France, and the Netherlands. While the negotiation of the treaty of Utrecht was in progress he fought a duel with a Frenchman for denying that Louis XIV. aspired to universal monarchy, and another with a Prussian for maintaining the same thing. He afterward fought against the Turks, and was severely wounded at the battle of Peterwardein. Having gone to Paris in 1717 to sue for a pardon, he was induced by his mother to marry a

daughter of Marshal de Biron, but deserted her ten days after and returned to the army of Prince Eugene, distinguishing himself at Belgrade and obtaining an important command in Sardinia and Sicily (1719). Being concerned in a lampoon on the associates of Eugene, he was sent to his regiment at Brussels, where he soon got into trouble with the governor of the Netherlands and was sent to the citadel of Antwerp. He made the matter worse by writing a letter to Prince Eugene which was construed as a challenge, and after trial he was sent beyond the border on condition that he should never set his foot on German soil again. He went first to Venice and then to Bosnia, where he was arrested and held in custody 15 months. Fearing that he would be delivered up to the Austrian authorities, he turned Mussulman, was made a pasha under the name of Ahmed, and undertook to reorganize the Turkish army. His propensity for getting into trouble still attended him, and in 1788 he was exiled to Asia. He finally appealed to his friends to secure his safe return to France. The pope offered him an asylum at Rome, and the king of the Two Sicilies a pension. A galley was sent to assist him to escape, but he died before he could effect his purpose. Various memoirs and collections of anecdotes concerning his adventures were popular in the last century.

BONNEVILLE, Benjamin L. E., an American soldier, born in France about 1795. He graduated at West Point in 1815, and in 1820 was employed in the construction of a military road through the state of Mississippi, and afterward on frontier duty till 1825. In 1831, receiving a furlough, he set out upon an exploring expedition beyond the Rocky mountains, and not being heard of till 1836, his name was dropped from the army list. His journal, edited and amplified by Washington Irving, was published in 1837, under the title of "Adventures of Captain Bonneville, U. S. A., in the Rocky Mountains and the Far West." Restored to the army, he served in the Indian territory and in the Florida and Mexican wars, becoming major in 1845 and brevet lieutenant colonel in 1847. He became colonel in 1855, was assigned to the command of the department of New Mexico, and in 1857 commanded the Gila expedition. In 1861 he was retired from active service for disability, and during the civil war served as superintendent of the recruiting service and chief disbursing officer in Missouri. In 1865 he was made brevet brigadier general.

BONNIVARD, François de, a writer and politician of Geneva, born in France in 1496, died about 1571. Coming into possession of a rich priory near Geneva, he heartily espoused the cause of that republic against the designs of the duke of Savoy, and in 1530 was arrested by the agents of Savoy and imprisoned in the dungeons of the castle of Chillon. He was restored to liberty six years later, when Chillon fell into the hands of his countrymen. He was employed from 1546 to 1552 in writing the

chronicles of Geneva, from the time of the Romans to 1530. He was versed in Latin literature, theology, and history, and left several works, which have remained in manuscript. He left a large collection of books to Geneva, from which has grown the public library of that city. The imprisonment of Bonnivard in the castle of Chillon forms the foundation of Byron's poem "The Prisoner of Chillon."

BONNY RIVER, one of the outlets of the Niger, at its delta on the coast of Guinea. Near its mouth is Bonnytown, which was once a place of great resort for slavers. Large quantities of palm oil are exported from this place. The country around the river is flat and swampy. The people are dirty and superstitious, and large numbers of them die every year from dysentery and fever, owing to the unhealthy climate.

BONNYCASTLE. I. John, an English mathematician, born at White Church, Buckinghamshire, died at Woolwich, May 15, 1821. He was for more than 40 years one of the mathematical masters at the royal military academy at Woolwich, and published introductions to arithmetic, algebra, astronomy, geometry, and trigonometry, an edition of Euclid's "Elements," and a general history of mathematics from the French of Bossut. **II. Charles**, son of the preceding, born at Woolwich in 1792, died at Charlottesville, Va., in October, 1840. He assisted his father in preparing his mathematical text books, wrote various articles for cyclopædias, and when the university of Virginia was founded was selected to occupy its chair of natural philosophy. He arrived in this country in 1825, was transferred to the professorship of mathematics in 1827, and was the author of a treatise on "Inductive Geometry" and of several memoirs on scientific subjects.

BONOMI. I. Giuseppe, an Italian architect, born in Rome in 1739, died in London, March 9, 1808. He went in 1767 to London, where he was employed as a draftsman. In 1775 he married Rosa Florini, the cousin of his friend Angelica Kauffmann, and, excepting one year spent with the latter in Italy (1783-'4), he remained for the rest of his life in London, and in 1789 he was elected associate member of the royal academy. He was the architect of the chapel of the Spanish embassy, of Eastwell house, Kent, of the pyramidal mausoleum in Blickling park, Norfolk, and of other famous structures; but his masterpiece was the duke of Argyll's country seat, Roseneath, Dumbartonshire, which he did not live to finish. **II. Joseph**, an English archaeologist and author, son of the preceding, born in London in 1796. He studied under Sir Charles Bell, at the royal academy, and in Rome, and spent many years in Egypt and Syria. He was the first to point out the monument erected by Sesostris on the coast of Syria, as mentioned by Herodotus, and has written on Egyptian archaeology for various publications of learned societies. His works include "Nineveh and its Palaces: the Discov-

eries of Botta and Layard applied to the Elucidation of Holy Writ," with contributions by Lepsius and other Egyptologists (illustrated, London, 1852; 3d ed., 1857), and "The Sarcophagus of Oimeneptah I. described by Samuel Sharpe" (1864). Mr. Bonomi is curator of Sir John Soane's museum, London.

BONONCINI, or **Buononcini**, **Giovanni Battista**, an Italian composer, born at Modena about 1670, died after 1752. He became known at Vienna as a composer of operas, and the royal academy of music invited him to London to compose for the stage. Handel was invited at the same time, and the two became rivals in popular favor, the Tories favoring Handel and the Whigs Buononcini. The former steadily gained the ascendancy, and Bononcini became a pensioner on the duchess of Marlborough, who had led his admirers. Having palmed off a madrigal as his own which he had merely copied, he was obliged to leave London, and was subsequently composer for the chapel of the king at Paris. He finally went to Venice, where all trace of him is lost. None of his operas have retained their popularity.

BONPLAND, **Aimé**, a French traveller and naturalist, born at La Rochelle, Aug. 22, 1773, died in Uruguay in May, 1858. He studied medicine, and served as a surgeon in the navy during the French revolution. He afterward pursued scientific studies with Humboldt at Paris, and accompanied that naturalist on his travels in Mexico and South America. They were absent five years, and on their return in 1804 Bonpland presented his collection of plants, numbering 6,000, to the museum of natural history. Napoleon gave him a pension, and the empress placed him in charge of her gardens at Malmaison. While in this position he published descriptions of the plants which he had collected, with illustrations. After the fall of the emperor he embarked again for South America, landing in Buenos Ayres in 1816 with a large collection of European plants and seeds. He was made professor of natural history in that city, and remained there five years. He then set out to carry on new explorations among the Andes, but was intercepted by Dr. Francia, the dictator of Paraguay, and detained for nearly ten years, during which time he was compelled to act as physician to a garrison. On his release in 1831 he retired to a plantation near San Borja on the southern boundary of Brazil, where he married an Indian woman and devoted himself to cultivating Paraguay tea. In 1853 he removed to a larger estate at Santa Anna, where he raised orange trees. During all this time he made collections of plants and wrote descriptions of them, which he intended to take to the museum at Paris, had he not been prevented by death. His most important contribution to Humboldt's *Voyage des régions équinoxiales* is *Nova Genera et Species Plantarum*, edited by C. S. Kunth (7 vols. fol., 1815-25). His biography has been written by Adolphe Brunel (Paris, 1872).

BONSTETTEN, **Charles Victor de**, a Swiss author, born in Bern, Sept. 3, 1745, died in Geneva, Feb. 3, 1832. Before the revolution he took part in public affairs and interested himself in social and political questions. Afterward he travelled extensively, writing letters, sketches, and books on a variety of subjects, both in French and German. He was acquainted with nearly all the distinguished persons of his time, and left some unfinished *Souvenirs*, in which he intended to record his reminiscences of them. His principal works are *Recherches sur la nature et les lois de l'imagination* (Geneva, 1807), and *Études de l'homme* (Geneva, 1821).

BONVICINO, **Alessandro**, called **Il Moretto da Brescia**, an Italian painter, born in Brescia early in the 16th century, died about 1560. Being a pupil of Titian and a careful student of the works of Raphael, he succeeded to a remarkable degree in combining the excellences of the two. He painted several historical pictures of celebrity, but excelled mainly in portraits.

BONZES, a term applied to the priests of Fo or Buddha in China, Japan, Cochin China,

Japanese Bonzes.

Burmah, &c. They are divided into various sects, but their teachings are much alike, and they have many customs in common. They profess celibacy, practise austerities of various kinds, and dwell together in monasteries. They always go with the head bare and closely shaven, and wear no beard. They are supposed to lead a life of prayer and contemplation, and at intervals teach the mass of worshippers in their temples. Among their moral teachings are strict honesty, chastity, and temperance. In their public devotions they use idols, some of them very hideous, but the real

object of worship is an invisible spirit. There are female bonzes who live in convents, and to whom the education of girls is sometimes intrusted.

BOOBY, the English name for a genus of *pelecanidae*, the *dysporus* of Illiger, *morus* of Vieillot, *le fou* of the French; separated from the true pelicans by Brisson, under the name of *sula*. The term booby is applied by navigators to that species (*sula fusca*, Briss.) which inhabits the desolate islands and coasts of warm climates in almost every part of the globe. The old voyagers have left accounts perfectly consentaneous concerning the stupidity of these birds, and testify to the passive immobility with which they sit in rows, two and two, along the shores, and suffer themselves to be beaten to death with clubs, attempting only a weak defence by pecking at their aggressors, and never making so much as an effort to take wing. Dampier says that in the Alacrane islands, on the coast of Yucatan, the crowds of these birds were so great that he could not pass their haunts without being inconvenienced by their pecking. He also states that he succeeded in making some fly away by the blows which he bestowed on them; but the greater part remained in spite of all his efforts to compel them to take flight. The boobies seldom

no reason for doubting the truth of this story. They walk with extreme difficulty, and while at rest on land stand nearly erect, propped, like the penguins, on the stiff feathers of the tail. The omission of all efforts for self-preservation by this bird is to be attributed not to stupidity, but to inability to get away, the extreme length of its wings and comparative shortness of its legs rendering it difficult for the bird to rise at all from a level surface, and almost impossible to do so in a hurry. They ordinarily lay their eggs, each bird two or three, in rude nests on ledges of rock covered with herbage; but Dampier states that in the isle of Aves they build nests in trees, though they have been always observed in other places to nest on the ground.

BOODROOM. See HALICAENASSUS.

BOOK, by the law of England, is "construed to mean and include every volume, part or division of a volume, pamphlet, sheet of letter-press, sheet of music, map, chart, or plan separately published." The word comes to us from the Saxon *bōc*, "beech," because the Saxons usually wrote upon beechen boards; just as the Latin *liber* denoted originally the inner bark of a tree, which was employed for the same purpose. It has, however, received an application anterior to its own origin, and is also used with reference to written tablets of stone and metal. In its widest sense it dates from the most remote antiquity. The ten commandments were written on slabs of stone; the Babylonians and Egyptians traced inscriptions on bricks and rocks. Sheets of wood, ivory, and various metals, and subsequently a great variety of pliable substances, animal and vegetable, crude and prepared, have been used for the purpose. The bark of the birch forms a very good writing material; and the leaves of the talipot palm are to this day used by the Cingalese for large books; the writing is performed with a sharp metallic point, and a black pigment is rubbed into the lines. In the library of the university of Göttingen is a Bible of this kind containing 5,373 leaves. Among the Greeks and Romans books of wood were common. For the more important purposes they also employed ivory, as well as bronze and other metals; and for common business, such as the recording of contracts and the making of wills, and for the courtesies of social life, the letters of love or friendship, they had sheets of wood, covered with wax, to be written upon with a *stylus*, and protected from contact by a raised margin, or opposite projections in the centres. Many specimens of ancient books still exist, which prove, without historical evidence, how various are the materials which suffice for the wants of man in an unlettered age. The most ancient books extant, with the possible exception of a few Egyptian papyri, are probably those brought from the ruins of the palace of Koyunjik, at Nineveh, dating from about 667 B. C. They consist of tablets of burned clay, some 9 inches by 6½, others much smaller, covered

Booby (*Sula fusca*).

swim and never dive, but take fish by darting down from on high, with unerring aim, upon such kinds as swim near the surface, and instantly rising again into the air with their booty. In the performance of this exploit they are often harassed and persecuted by the frigate birds and albatrosses, which give chase to them the instant they see them rising laden with their prey, and force them to disgorge it, when they themselves appropriate the fish. Recognizing the similar habit of the whiteheaded eagle toward the osprey, of the great arctic gull toward the fishing terns, and of other predatory birds toward their more industrious and peaceful congeners, there is

with cuneiform characters, sometimes so minute as to be almost illegible without a magnifying glass; they had been impressed upon the moist clay, which was afterward baked. So numerous were they that the floors of two rooms were covered a foot deep with them. They had been originally paged and placed in cases. In the destruction of the palace they were broken; but there were four copies of each, so that what is wanting in one is often supplied by another. This library is now in the British museum. The antiquary Montfaucon in 1699 purchased at Rome a leaden book of six thin leaves, about 4 inches long by 8 wide, with hinges and clasps of the same material; it contained Egyptian Gnostic figures, and other unintelligible writing. Among the Calmuck Tartars was found a collection of books that were long and narrow, the leaves very thick and made of bark covered with varnish, the ink being white on a black ground. M. Santander

transcription, and elaborateness of ornamentation, but upon the favor in which particular authors happened to be held, seems to have gone to each extreme; instances of extraordinary cheapness standing side by side with others of almost incredible dearness. According to Böckh, in Athens, "a small book (*γρᾶμμαρίδιον*) for the purpose of recording a contract, that is, a small, commonly wooden diptychon, consisting of two wax tablets, was estimated by Demosthenes at two chalci (one quarter of an obolus, less than one cent). Wooden tablets (*σάβιδες*), on which accounts were written, cost, Olymp. 93, 2 (B. C. 407), a drachma (about 18 cents) apiece. These must have been pretty large and well made. Two pieces of papyrus for copying an account cost at the same time two dr. four ob. (45-6 cents). Paper appears from this to have been very dear, although written books were cheap since the books of Anaxagoras, even when dear, were

to be had for a drachma; or else the paper upon which public accounts were written was uncommonly good." It is also stated that Plato, who was not rich, bought three books of Philolaus the Pythagorean for 10,000 denarii (about \$1,600); and it is further said that Aristotle paid three Attic talents (nearly \$3,000) for a few books which had belonged to the philosopher Speusippus. But these apparent contradictions may be easily reconciled by a consideration of the probable conditions

Ancient Books and Writing Implements.

possessed a beautiful Hebrew Pentateuch, written on 57 skins of leather, sewed together with threads or strips of the same material; it formed a roll 113 French feet in length.—The shape of wooden and metal books was square, but when more convenient material, such as parchment and papyrus, was introduced, the cylindrical form was adopted. The sheets, fastened together at the edges, were attached to a staff, round which they were rolled; whence our word volume, from *volvere*, to roll. At each end of the staff was a boss by which it could be turned, and the volume was read by unrolling the scroll so as to expose successively its several sheets. The title was written generally in red, on fine vellum, and pasted on the outside. Scrolls were again superseded by square books. Modifications in form accompanied the various changes made in material, until the shape and general proportions which now prevail were adopted.—The value of books, depending not only upon beauty of chirography, accuracy of

that occasionally existed; the number of certain works reducing them to the value of the transcriber's labor, or less, when supply exceeded demand, while the rarity of others gave a practical monopoly to their possessors.—At Rome the manufacture of books, which under the early emperors had been constantly increasing, diminished during the troubles of the empire, and upon its fall was for a long time entirely extinguished; to revive again after many years, but under greatly altered circumstances. In the dark ages the material for writing became scarce. The supply of papyrus from Egypt failed, and paper had not been introduced from the East. Parchment was almost the only accessible material, and for this the demand far exceeded the supply. Hence arose the practice of erasing the original writing from the parchment so that it could be used again. The erasure was usually made by rubbing with pumice stone; but as the coloring matter of the ink penetrated a little into the texture of the

parchment, the erasure was seldom complete, and the original writing can often be made out. Several valuable works have thus been recovered. A manuscript of this kind is termed a palimpsest (Gr. *παλίμψητος*, from *πάλιν*, again, and *ψῆν*, to rub off). Had not paper, properly so called, been already common in Europe, the invention of printing, superseding the labor of the copyist, would have been of little value for the multiplication of books.—In the earliest times books had been ornamented; but in the middle ages they reached the acme, if not of beauty and convenience, at least of cost. In the process of preparation books then received the most careful attention. In the monasteries the monks were not only transcribers, illuminators, and binders, but the same individual frequently combined the triple function in his own person. From the hands of the scribe the book passed to the illuminator, and from him to the binder, by whom its ponderous proportions were encased in massive covers of wood and leather, studded with knobs and bands, often of gold and silver, and closed with broad clasps. When publicly exposed, they were frequently secured by chains; nearly every great library contains books, often printed ones, with the chains still attached. Books were protected by special statutes; were subjects of grave negotiations; were solemnly bequeathed by will; and were lent only to the higher orders, who were compelled to deposit ample pledges for their return. Even so late as 1471 Louis XI. was compelled by the faculty of medicine at Paris to deposit a valuable security, and give a responsible indorser, in order to obtain the loan of the works of the Arabian physician Rhazes. Among the illustrations of cost which the industry of bibliographers has collected, we find that St. Jerome, to procure the works of Origen, impoverished his estate; that King Alfred gave for one book eight hides of land (480 to 960 acres); that the countess of Anjou paid for a copy of the homilies of Bishop Huiman, besides other articles of barter, 200 sheep. Stowe says that in 1274 a Bible finely written sold for 50 marks (about £34), at a time when wheat was 5*d.* a bushel, and labor 1*d.* a day; in 1400 a copy of Jean de Mehun's "Romance of the Rose" was publicly sold at Paris for 40 crowns (more than \$150). But, according to a document in the monastery of St. Stephen at Caen, the works of Peter Lombard were bought in 1431 for 7 francs. It is thus difficult to ascertain the prices of books as determined by the value of material and labor at remote periods; for the peculiar instances which have been placed on record are more likely to refer to exceptional and accidental conditions than to the ordinary and usual rates affixed by the understood laws of trade. Something of the same kind occurs in our own time; a book whose intrinsic value is but a few shillings, has often been sold for scores or even hundreds of pounds. (See BIBLIOMANIA.)—Printing made

no immediate or violent innovation upon the then existing order of things. Types were made to imitate the products of the slower process of writing, and the general appearance of MS. volumes was carefully imitated, so that for some time books still continued inaccessible to the people. But the desire for books was almost imperceptibly growing, the gradually widening demand keeping pace with and encouraging the development of mechanical skill. Copies were multiplied with increasing rapidity and diminishing cost, and their sale becoming larger, while it reduced the proportionate expense, enlarged the aggregate profits of the maker. Nevertheless, in Europe, even long after the invention of printing, books were beyond the reach of the people, even had they been able to read. In China, and probably in Japan, printed books have been common and cheap from time immemorial. Their method of printing, which has undergone no important change for generations, enables them to produce a book much more cheaply than it could have been done with us half a century ago. Twenty-five or thirty pages for a cent is, and appears to have long been, a common price for an ordinary book; a cent, however, representing a much greater value there than here.—With us the manufacture of a book demands a large outlay of capital and the aid of various branches of mechanical skill. Strictly speaking, the making of a book begins with the author who writes it, or, as in the case of a collective work like a cyclopædia or a gazetteer, the corps of editors, writers, and revisers. Then follow, in regular sequence, the compositor, proof-reader, pressman, and binder; and if the work is one of which a considerable number is to be printed, and is illustrated, the stereotyper or electrotyper, and the engraver on wood, copper, steel, or stone (lithographer), or perhaps two or more of them, will also be called into requisition. (See BOOKBINDING, CORRECTION OF THE PRESS, ELECTRO-MAGNETISM, ENGRAVING, LITHOGRAPHY, and PRINTING.) In respect to the size of their pages books receive several designations. Originally these denoted the number of leaves into which each sheet was folded. In a folio, the sheet was folded once, making two leaves; in a quarto (4to), twice; in an octavo (8vo), three times, making 8 leaves; in a duodecimo (12mo) the sheet made 12 leaves, but four leaves had to be cut off from one end of the sheet, folded separately, and placed in the centre of the other part, when folded. These terms are now used only in a general way, to indicate the size of a book. The introduction of power presses permitting the use of larger sheets, it is very rarely that a work is now printed in folio, or even in quarto, although a volume of very large size is still styled a quarto. This Cyclopædia is a large octavo; a volume somewhat smaller is simply an octavo; the next smaller size is crown octavo; then come duodecimo, 18mo, 36mo, and so on.—All printers are not pub-

lishers or booksellers; and all booksellers are not printers. The distinction is this: A printer is one who prints a book, either for himself or for another; a bookseller is one who vends books, either at retail or by wholesale, whether printed by himself or another; a publisher is one who prepares a book for the market, and issues it to the public. A few publishers confine themselves exclusively to the sale of the books issued by themselves, but most of them also buy and sell the books of others; so that while all booksellers are not publishers, all publishers are booksellers. Few authors have the facilities requisite for getting up their works and placing them before the public. For this they must avail themselves of the agency of the publisher, who usually undertakes all the expense, and so demands a share in the profits. The author's pecuniary right in his book is termed a copyright, that is, the exclusive right to produce a copy of it, for a certain period, and under certain conditions prescribed by the law, which creates this exclusive right. (See COPYRIGHT.) Usually the author disposes of his copyright to a publisher; sometimes he sells it outright for a stipulated sum; generally he prefers to receive a certain portion of the profits. This varies greatly, but the most common rate is 10 per cent. on the retail price of each copy sold. Some authors obtain much more; and in the case of school books, which are usually sold at a small advance upon the cost of production, the author's percentage is often smaller. In Great Britain a frequent arrangement is that the author and publisher shall divide the net profits equally; but this is liable to the objection that it is not easy to fix the expenses belonging to each separate book, and there is always a contingent risk that a part of the copies may remain unsold, or that bad debts may be incurred. By the American method the publisher usually assumes all risks, and the amount due the author can be at any moment ascertained.—The first regular bookseller in the United States appears to have been Hezekiah Usher, who was in business in Boston as early as 1652. He was succeeded by his son, John Usher, who in 1686 was described as a "trader who makes the best figure in Boston; he's very rich, adventures at sea, but has got his estate by bookselling." Books were mainly imported, and were kept in shops with other wares; thus Benedict Arnold sold drugs and books; usually, however, the occupations of printer, bookbinder, and bookseller were combined. In 1732 Richard Fry, a Boston bookseller, advertised that he had printed "the most beautiful poems of Mr. Stephen Duck, the famous Wiltshire poet," and considered the fact that he had sold 1,200 of these poems "a full demonstration that the people of New England have a fine taste for good sense and polite learning." Toward the close of the last century bookselling began to assume a prominent place among commercial pursuits. About 1820 it began to increase rapidly, and

it has since more than kept pace with the increase of population. In the 12 years from 1830 to 1842, the entire number of books printed in the United States was about 1,300, an average of over 100 a year, about equally divided between original works and reprints. The number of publications steadily increased from year to year. In 1853 there were 879 new books and new editions, of which 298 were reprints of English works, and 37 translations from other languages. In 1855 the new books and new editions were 1,092, of which 250 were reprints of English books, and 38 translations. During the years 1859-'60 the number of books averaged about 1,350 a year. The civil war somewhat checked the book trade, but it revived after its close. In 1871 the number of books published in the United States was about 3,000; of which 50 may be designated as works of reference, 350 theology, 30 mental and moral philosophy, 200 political and social science, 200 education, 800 history, geography, and travels, 450 sciences and arts, 200 fine arts and recreation, 350 general literature, 570 juvenile, and 300 fiction. Many of these works comprise several volumes, so that the number of volumes is about 3,500. The value of the books manufactured in the United States in 1820 is estimated at \$2,500,000; in 1830, \$3,500,000; in 1840, \$5,500,000; in 1850, \$12,500,000; in 1856, \$16,000,000; in 1871 it can hardly be less than \$40,000,000.—The cost of producing each copy of a book depends greatly upon the number printed, for there is a certain expense for setting the type, &c., which must be incurred, no matter whether the number be great or small. This in the case of an ordinary 12mo may be set down at \$750. If 1,000 copies be printed, it will be 75 cents a copy; if 5,000 copies, 15 cents a copy; if 10,000 copies, 7½ cents a copy. The paper, printing, and binding of each copy of such a work cost about 40 cents, or somewhat less for very large numbers. If, now, 1,000 copies are printed, the cost of the mere manufacture of each will be \$1 15; if 5,000 are printed, 55 cents; if 10,000, 47½ cents. The usual retail price of such a book is \$1 50; and deducting the discount to the trade, and certain inevitable minor expenses, the publisher receives \$1 a copy. His account would stand thus: For 1,000 copies—cost \$1,150, receipts \$1,000, loss \$150; for 5,000 copies—cost \$2,750, receipts \$5,000, profits \$2,250; for 10,000 copies—cost \$4,750, receipts \$10,000, profits \$5,250. From these must be deducted, in the case of an original work, the author's copyright of .15 cents a volume. This on 5,000 copies is \$750; on 10,000, \$1,500. The apparent profits of the publisher are twice those of the author on 5,000 copies, and two and a half times on 10,000; but out of this must come the expenses of conducting business, cost of advertising, losses by bad debts, and the cost of unsold copies. In a fairly successful book, the net profits of the publisher are

about equal to those of the author; in the exceptional cases of a very large sale, they are usually considerably greater; but the authors of such works command more than the usual copyright, so large occasionally as to absorb the greater part of the profits, in which case the publisher is in effect merely the business agent of the author. Still it is true that every purchaser of a book, as a rule, pays more to the paper maker, the printer, and the binder, respectively, than to the author. A successful publisher, indeed, usually receives more than a successful author; for the reason that the former derives his income from scores, hundreds, or thousands of different works, while the latter derives his from only the few which he has himself written.—The great majority of individual volumes have only a brief life. Of those printed more than 20 years ago probably not one in five now exists. The others, by steps more or less rapid, have found their way to the flames or the waste basket, and thence to the paper mill, whence their material substance reappears in the shape of paper or bookbinders' boards.

BOOKBINDING, the art by which the material parts of a book are connected for convenience in use and protection from injury. Its antiquity is coeval with the art of composing books, for from whatever materials ancient books were made—wood, slate, horn, plates of lead or copper, the leaves or bark of trees—the necessity arose of uniting the several parts together for more ready reference as well as their better preservation. The art probably first consisted in fastening together sheets of wood or metal by means of hinges. Afterward, when the more pliable substances papyrus and parchment were substituted, the sheets were fastened together at the edges and fixed at one end to a scroll round which they were rolled. The bookbinder then as now prepared the volume, made the staff, affixed the bosses and the title, and embellished the outside as his own or his patron's taste might suggest. Dibdin, on the authority of Trotzius, an ancient scribe, asserts that Phillatius was the discoverer of a substance for making the sheets adhere together, and that the Athenians erected a statue in his honor. He also says, on the authority of Vossius, that King Attalus of Pergamus first ordered the squaring of books, and that this gave rise to the folding into twos and fours, or folios and quartos; and after the folding, gathering, and glueing of the book, covers of board, vellum, or leather naturally followed.—Bookbinding involves considerable mechanical skill and knowledge of decorative art; for from its commencement it has gone beyond the mere necessities of utility, often to heights of notable extravagance. In respect of expense the limits have never been defined, ostentatious display having at times superseded the binder proper by the goldsmith and lapidary. Thus St. Jerome exclaims: "Your books are covered with precious stones, and Christ died naked

before the gate of his temple." Jewels and precious metals, the finest stuffs and the most gorgeous colors, united to give a material value, frequently without any elegance of design or chasteness of taste. All great public collections show with pride some of these rare and venerable bindings, decorated with gold and inlaid with precious stones, cameos, or antique ivories. The cathedral of Milan contains in its treasury the covering of a book of a date prior to the 12th century, 14 inches long and 12 inches wide, profusely covered with incrustated enamel, mounted and ornamented with polished but uncut precious stones of various colors. Skelton's description, though purely fanciful, will convey an idea of what was in his time acceptable as the perfection of book decoration:

With that of the boke losende were the clasps:

The margent was lilymynd all with golden railles

And byse, enpicturid with gressoppes and waspils,

With butterflyis and freshe pecko tayls,

Enflord with flowris and slymy snaylis;

Enuynd picturis well towchid and kulkly;

It wolde haue made a man hole that had be ryght sekely,

To beholde how it was garnyschyd and bounde,

Encouerde ouer with golde of tisseu fyne;

The clasps and bullyons were worth a thousande pounde;

With balaisis and charbuncles the borders did shyne;

With *aurum muscum* every other lyne

Was wrytyn.

This mode of decoration, however, was the work of goldsmiths, enamellers, &c., and quite foreign to the bookbinder's art. In specimens of oriental binding brought home by the crusaders, European workmen found models for the dyeing, stamping, and gilding of leather, which did much to advance the art. A marked change in the character of binding and its decoration took place as books began to multiply by the invention of printing. To such patrons as Grolier, De Thou, and Maioli, of the sixteenth century, binders are indebted for those chaste and elegant designs which form their best examples at the present day. Since that period many styles have sprung into existence which have each their admirers, the Harleian, Montagu, Roxburghe, &c. In our own times bookbinding has wonderfully improved in style, design, and cheapness. France, England, and America have each characteristically contributed toward this improvement, while Germany, where printing was invented, has lagged behind. France has excelled in her taste and finish, England in solidity and strength without sacrifice of flexibility, and America by the invention and use of machinery vastly increasing the speed of production, a single bindery in New York being capable of producing 10,000 bound books a day.—The introduction of cloth binding is an important feature in the progress of the art. The number of modern publications and the extent of the editions necessitated a style both economical and rapid in its production. To Mr. Pickering, the London publisher, and Mr. Leighton, the binder, belongs the credit of its introduction about 40 years ago. The paper label was its first and only ornament,

afterward the title in gold; but now it receives the most elaborate gilding, and of late years elegant and emblematic designs of ink and gold in combination are produced. This style has given rise to the greater part of the machinery used in bookbinding, and to the United States the credit of the invention of three fourths of it belongs. Sheep skin is extensively used, but morocco, russia leather, and calf form the covers of the more expensive binding. Occasionally velvet, ivory, and mother-of-pearl are used for Bibles and books intended for presentation.—There are two kinds of binding, a description of which will suffice to give a general idea of the mechanical processes through which a book passes after leaving the printer, before it is completed for sale. The first is cloth-case binding, the cheapest, and that in which machinery is most employed; the other is known as extra binding, the work on which is principally performed by hand. Taking the volume in which this article appears as an example, we shall first describe the manner in which it is bound in cloth. Books derive a technical name descriptive of size from the leaves into which each printed sheet is folded, such as folio, quarto, octavo, duodecimo, &c. At the foot of the first page of each sheet is a number or letter, called the signature, by which the order is designated. This volume is called a royal 8vo, being printed on paper a size larger than the ordinary 8vo, and is printed on nearly 50 sheets, each containing 8 leaves or 16 pages. These sheets go to the binder in quires, and are first taken to the sheet room, where the work of folding, gathering, collating, and sewing is done by females. The whole edition of each sheet is folded by one girl with astonishing rapidity and accuracy. The most expert will fold about 400 an hour, but the average is

from which they are taken one by one by the gatherer with the right hand, and then placed in the left, until a whole set is collected. This process, as well as that of folding, is performed with wonderful quickness, the gathering of

FIG. 2.—Book-Sewing Machine.

25,000 sheets a day being not unusual for an active girl. After this the sheets are knocked up evenly and examined by the collator, who looks at each signature to insure that the volume is complete, each sheet being in its proper order without duplicates or deficiencies. Being found perfect, the book is pressed in a smashing machine, by which the delay of the screw or hydraulic press formerly employed is avoided. It now passes to the sawing machine, preparatory to sewing. Several volumes are taken together, and in an instant five revolving saws make as many cuts in the backs, of a size sufficient to admit the bands of twine to which the sheets are sewed. The sewer has a wooden frame, which consists of a table with two upright screws supporting a horizontal and adjustable rod, to which three strong bands fastened on the table are attached, at distances corresponding to the three inner saw marks. She then places the first sheet against the bands and passes her needle from the first cut or kettle stitch to the inside of the sheet, then out and in at every band, embracing each with the thread until the bottom is reached, then sews the next sheet in the same manner but in an opposite direction, and so on alternating until the last. Within the last year (1872) book-sewing machines (see fig. 2) have been successfully introduced in America, which effect an average saving of one half the cost of hand sewing, and are simple and perfect in their operation. Henry G. Thompson of Connecticut is the patentee. End papers are now pasted on the book, which then leaves the sheet room, where about 1,000 are so prepared in a day. In the forwarding room, which it enters

FIG. 1.—Folding Machine.

perhaps 300. Folding machines (see fig. 1) are now in general use capable of folding 10,000 or 12,000 sheets a day. After having been folded, the sheets are laid in piles, according to the order of the signatures, on the gathering table,

next, its further progress is effected mainly by the aid of machinery. It is first prepared for the cutting machine, and, after its fore edge has been cut, is glued and rounded by the workman, then returns to be cut on the ends, after which a piece of muslin is pasted over the back nearly as long as the book, but extending about an inch over its sides to give strength to the joints. A backing machine then spreads the back and forms a groove for the boards; two paper linings are now glued to the back, and the book is ready for its cover, which has in the mean time been prepared in another department. The case or cover is simply and expeditiously made, and is composed of mill boards cut a little larger than the size of the book, strips of paper the exact length and width of the back, and the cloth cut sufficiently large to turn over all. The cloth is glued, and one board placed upon it, then the paper at a short distance to allow for the joint, then the other board, after which the corners of the cloth are cut, the edges turned over, and it is rubbed smoothly down. When dry, it is given to the stamper, who letters it in gold and embosses the sides. The letters are engraved on a metal stamp, and the impression is made in an embossing press, heated by steam. Gold leaf is laid on the cover, and the heated stamp causes it to adhere where desired, the unused gold being afterward wiped off with a rubber. Then the book is pasted on the sides, placed in the cover, and pressed till dry. This completes the process of case binding, which is distinguished more particularly from extra binding in having the book forwarded separate from its cover; and it may be useful to learn that some bookbinders pursue the same plan with morocco as with cloth, producing inferior work, not readily detected by the purchaser until after the volume has been some time in use.—Morocco or other extra binding will now be described. Though folded and gathered the same as the cloth copy, greater care is taken in pressing, and it is sewed in a different manner. The back is not sawed, but the bands, to the number of five in this volume, have their positions indicated by pencil marks. Instead of passing the needle out at the upper and in at the lower side, merely drawing them to the book, it is passed out at the lower and in at the upper, completely encircling the band, and forming a flexible hinge for the sheet. This is called flexible or raised band sewing, and constitutes one of the distinguishing features of strong binding, being not only important but indispensable. The forwarder now receives the volume, pastes on and breaks up the end papers, glues the back, and when dry rounds it; after which the backing boards are placed on the sides a short distance from the back, and it is then screwed up in the laying press, and the back hammered very carefully, so as to spread the sheets on each side of the backing boards, at the same time not wrinkling the inside. By this process grooves are formed for

the mill boards, which, being cut of the desired size, are placed on the sides, and the book is subjected to a powerful pressure, during which the refuse glue is soaked off with paste, and the back is rubbed smooth and left to harden. It is now in shape, but with all the leaves uncut. No new machine has yet been made to supersede the old press and plough for cutting a book "in boards." The mill boards are put close in the joints and even with the head of the book, the front board placed as much below the head as may be desired; the book is fixed tightly in the press, the head of the front board being on a level with it, and the head is cut; the same operation is repeated for the foot or tail, the boards being left larger than the book in order to overlay and protect the edges. The fore edge is formed differently. A cord is wound tightly round the volume parallel with and close to the back, which is then beaten flat, and the fore edge cut straight; and upon the release of the book from the cord by which it is bound, the back resumes its round, and the fore edge becomes grooved. The edges are now gilded, for which purpose, the books being pressed, they are scraped smooth, and covered with a preparation of red chalk as a groundwork for the size, a mixture of the white of egg and water, in the proportion of one egg to about half a pint of water. The gold is laid on the size, allowed to dry, and then burnished with an agate or bloodstone. Before being covered, head bands of silk are fixed to each end of the back, projecting a little beyond the sheets, and making the back the same length as the boards. The boards are bevelled at the edges, by means of a machine which grinds them with emery dust. The cover, pared thin, is now pasted on and drawn tightly over, but is afterward taken off for convenience in turning in the edges. The back, which has no lining, is well pasted, the cover drawn on again, the bands well nipped up, and great care is taken to make the leather adhere firmly to the back, and to set the boards closely and well forward in the joints. A book thus sewed and covered possesses the primary essentials of strong binding. The ornamenting or finishing is much a matter of taste within certain limits. The process by which decorative impressions are made on the outside of a book is called tooling, and when gold is not used blind tooling. A beautiful effect is produced on morocco by the latter, making those glossy black indentations which so tastefully contrast with the rich color of the leather. For this purpose the tools or stamps are heated and applied repeatedly to the morocco, which has been made thoroughly wet. End papers being neatly pasted to the boards, the book is finished.—The foregoing will serve to point out the several processes through which the sheets pass before the book is completed, as well as to exhibit the distinguishing characteristics of the two principal styles of binding. The hollow or spring back, which is in much favor,

and adapted in a superior degree to books in calf, is yet subject to rupture, and demands the binder's best attention. By securing the back always with muslin instead of paper, its strength will be greatly increased. India-rubber binding, by which the leaves are fastened together with a cement of caoutchouc, though admirably adapted for allowing engravings to be opened to their full extent, is a failure for want of strength.

BOOKKEEPING, the method of exhibiting in a clear and concise manner the state of a man's pecuniary affairs. The system of bookkeeping in general use among men of business, called the "Italian method," from the country of its invention, and "double entry," from the construction of its ledger, is of great antiquity. The first treatise on the subject was written by Luca Pacioli, better known as Luca di Borgo (Venice, 1495). The first German treatise on bookkeeping was written by Johann Gottlieb (Nuremberg, 1531). In 1548 Hugh Oldcastle produced at London "A profitable Treatise to learn to knowe the good order of the keyping of the famous reconynge, called in Latin, *Dare et habere*, and in Englyshe, Debitour and Creditor." In 1602 a work in French on double entry appeared at Leyden, followed in 1652 by Collins's "Introduction to Merchants' Accounts." Mair's "Bookkeeping Modernized," the most elaborate exposition of the old Italian school published, appeared the following century, and passed through many editions. In 1789 Benjamin Booth modified the system, introduced many valuable improvements, and gave to the world the first and best work extant on the modern practice of monthly journalizing, under the title of "A Complete System of Bookkeeping," an improved mode of double entry, comprising a regular series of transactions, as they have occurred in actual business.—The following are the fundamental principles upon which the science of double entry is based: The essentials of this art consist in the classification and arrangement of data in a book called the ledger. Each collection of data is called an account. An account, whether of persons or things, is a statement of all the transactions whereby the property of the concern has been affected by the person or thing in question. The accounts are designated by distinct titles, and articles of opposite kinds are placed in opposite columns. The space which an account occupies in the ledger being vertically divided, the left-hand side is denominated debtor and the right-hand side creditor. These terms, when applied to the personal accounts, are used in their ordinary sense; but when applied to an impersonal account, they have a more extended signification. All debit items are not sums owing to the concern, nor are all credit items sums owing by the concern; in short, the terms Dr. and Cr. serve merely to distinguish the left from the right-hand side of an account, and the arithmetical signs *plus* and *minus* would equally answer

this purpose. The nature and object of the principal accounts in a merchant's ledger are briefly as follows: 1. The receipts and payments of money are recorded under the title of cash. All receipts are entered in the left or debtor money column, and all payments in the right-hand or creditor money column. The difference between the two sides, technically called the balance, represents the cash in hand. 2. Written securities, such as drafts, notes, or acceptances, received by the merchant, and for the payment of which other parties are responsible, are recorded under the title of bills receivable, and those issued or accepted by the merchant, for the payment of which he is responsible, are recorded under the title of bills payable; the former account invariably represents assets, and the latter liabilities, in the shape of bills. 3. An account must be opened for each person or firm with whom the merchant has dealings on trust under their respective names, or the name of the firm with which they are connected. The design of a personal account is to show what is owing to or by the person in question. The terms debtor and creditor are here used in their ordinary sense; since each person is made debtor for what he owes, and creditor for what is owing to him. 4. Purchases and sales are recorded under the name of the specific property bought or sold; the cost or outlay being entered on the debtor side, and the sales or returns, as well as the value unsold, at the time the accounts are adjusted, on the credit side. The result is gain or loss as the case may be. 5. The capital invested in business, in the outset, is recorded under the title of stock, or capital stock, and the gains and losses under the double title of profit and loss. Commission, charges, interest, and the like are merely subdivisions of the profit and loss, and the latter is simply a branch of the stock account. The stock account exhibits the capital collectively, that is, in one mass; the other accounts exhibit its component parts. The fundamental law of double entry is this: every transaction which affects or modifies the capital, or its component parts, must be twice entered; that is, to the debit of one or more accounts, and *vice versa*. When the accounts are completed, there remains the last process, which consists in balancing the books; that is, in closing and equilibrating the several accounts, and in collecting the results, so as to exhibit in a concise form the gains and losses, the assets and debts, and the present capital. This is generally done at stated intervals on a balance sheet which contains every account of the ledger. Every transaction in business being virtually a transfer between two accounts, it must be entered to the debit of the one and to the credit of the other; these two balancing entries are made in the ledger, and comprise all that is scientific in the system of double entry. The entries in the primary books are merely preparatory arrangements, totally

unconnected with the principle and proof of accounts. The most indispensable preliminary in the process of bookkeeping is the registration of all the data of which the accounts are composed in chronological order, and in language as clear and concise as possible. The subsidiary books in general use are: The cash book, which contains a daily record of the receipts and payments of money; the bill book, which contains a daily record of the bills, notes, or acceptances received and issued; the invoice book, which contains the particulars of goods purchased, and is simply a transcript of the invoices or bills of parcels; the sales book, which contains the particulars of goods sold on credit, or shipped abroad on consignment; the day book, which is used to record such transactions as do not properly belong to either of the other subsidiary books. The journal is a record of the transactions compiled from the subsidiary books, daily, weekly, or monthly, as may be expedient. The rules for distinguishing the accounts which are to be debited and credited are inferred from the arrangement of the ledger. The thing received, or the person accountable to you, is debtor; the thing delivered, or the person to whom you are accountable, is creditor; thus: 1. The person to whom anything is delivered is debtor to the thing delivered when nothing is received in return. Therefore, when money is paid, the receiver is debtor to cash; when goods are sold upon credit, the purchaser is debtor to goods. 2. The thing received is debtor to the person from whom it is received when nothing is delivered in return. Therefore, when money is received, cash is debtor to the payer; when goods are bought on credit, goods are debtor to the seller. 3. The thing received is debtor to the thing given for it. Therefore, goods bought for ready money are debtor to cash; when goods are sold for ready money, cash is debtor to goods. 4. When one person delivers anything to another on your account, the person who receives the value is debtor, and the person who gives it creditor.

BOOLAK, *Boulak*, or *Bulak*, a town of Egypt, on the Nile, 1 m. N. W. of Cairo, of which it is the port; pop. about 5,000. In 1799 it was burned by the French. Mehemet Ali rebuilt it, and established extensive cotton-spinning, weaving, and printing works, a school of engineering, and a printing establishment, renowned for its productions in Arabic, Persian, and Turkish, from which is issued a weekly newspaper in Arabic. The town contains a naval arsenal, a dockyard, and a custom house, and is surrounded by the country residences of numerous Egyptian grandees.

BOOLUND SHAHUR, or *Boalundshahur*. **I.** A British district of Hindostan, in the Northwest Provinces, division of Meerut; area, 1,823 sq. m.; pop. about 800,000, more than three fourths Hindoos. It has a level surface, sloping gradually to the southeast, with a slight ridge rising between the courses of the Jumna

and the Ganges, which, with the Hindon and the East Kali-Nuddee, are the principal rivers of the district. The climate is subject to extremes unusual in that latitude. Domestic quadrupeds attain scarcely half the size of those in Bengal and Bahar. Cotton grows well, and constitutes the staple production. The other products are indigo, sugar, tobacco, wheat, barley, millet, and several kinds of pulse. Boolundshahur formed part of the territory acquired by the French adventurer Peron. He was routed by the British in 1803, when this district and other possessions were ceded to the East India company. **II.** Or *Burrn*, the chief town of the district, situated on the Kali-Nuddee, 40 m. S. E. of Delhi; pop. 12,000. It has a bazaar and considerable traffic. It was one of the centres of the sepoy rebellion of 1857.

BOOM, a town of Belgium, in the province and 10 m. S. of Antwerp; pop. in 1866, 10,064. It is situated on the Rupel, at the junction of the Brussels canal, and has an active transit trade. It contains a college, brick and tile works, tanneries, breweries, and various other manufactures.

BOOMERANG, *Bomerang*, or *Womera*, a missile for war, sport, or the chase, used by the aborigines of Australia. It consists of a piece of very hard wood about 2 ft. long, 2½ inches wide, and ¼ of an inch thick, bent to a parabolic curve, the ends rounded, and one side con-

Boomerangs.

vex, while the other is flat. It is taken in the hand by one end, with the convex edge forward and the flat side up, and projected as if to hit an object directly in advance. It gradually rises, rotating rapidly, and finally takes a retrograde motion and falls behind the projector. Its effective use requires a skill that Europeans find it next to impossible to acquire.

BOONDEE, or *Bundl*. **I.** A native state of Rajpootana, Hindostan, under British protection, separated from Kotah on the E. by the

Chumbul, and bounded S. by Sindia's territory; area, 2,291 sq. m.; pop. about 250,000. A range of mountains traverses it from N. E. to S. W., on each side of which the surface is level. The climate is unhealthy, fevers, rheumatism, ophthalmia, and bronchial affections being very prevalent. The majority of the inhabitants are Meenas, a predatory tribe, dwelling chiefly among the mountains, and supposed to be the early possessors of the district. The dominant tribe, however, to which the sovereign belongs, is that of the Haras. The territory subject to the rajah of Boondee was anciently of much greater extent than at present, and was called Haraoti. It is said to have been wrested from the Meenas by Rao Dewa in 1342. It was dismembered by Jehangir at the end of the 16th century, and the territory of Kotah set apart for a descendant of a former rajah. Other portions of the territory were lost in 1804, and in 1817 more than half the revenues were usurped by Holkar and Sindia. The rajah of Boondee having aided the British in the Mahratta and Pindaree wars, a treaty of alliance and friendship was made in 1818, by which Boondee regained its revenues and a portion of its lost domain. The importance of this state is due to the fact that it contains the principal passes to upper Hindostan from the south. **II.** The capital of the state, situated in a valley surrounded by rocky hills, 22 m. N. W. of Kotah, and 245 m. S. S. W. of Delhi; lat. 25° 28' N., lon. 75° 30' E. It is encompassed by walls with three massive gates, and inhabited chiefly by native Haras. Its advantages as a commercial town are very few, but the beauty of its situation, its antiquity, numerous temples, handsome fountains, and palaces, invest it with considerable interest. The residence of the rajah, which is a collection of splendid structures reared by different sovereigns, and each bearing the name of its founder, stands on the slope of a hill overlooking the town. The town is divided into old and new Boondee, the former of which is in a state of decay.

BOONE, the name of counties in seven of the United States. **I.** A S. W. county of W. Virginia, bounded N. E. by Coal river, a tributary of the Kanawha, and drained by its branches; area, about 500 sq. m.; pop. in 1870, 4,553, of whom 153 were colored. Its surface is hilly, and to a great extent covered with forests. The chief productions in 1870 were 2,585 bushels of wheat, 129,630 of Indian corn, 13,667 of oats, 12,043 of potatoes, 6,213 lbs. of tobacco, 9,699 of wool, 55,784 of butter, and 22,547 of honey. There were 565 horses, 1,356 milch cows, 2,448 other cattle, 3,955 sheep, and 4,848 swine. Capital, Ballardsville. **II.** A N. county of Arkansas, bordering on Missouri; area, about 800 sq. m.; pop. in 1870, 7,032, of whom 74 were colored. White river flows through the N. E. corner of the county. Most of the land is fertile and diversified. Excellent variegated marble is found.

The chief productions in 1870 were 41,940 bushels of wheat, 341,042 of Indian corn, 22,337 of oats, 12,394 Irish and 10,027 sweet potatoes, 206 bales of cotton, 56,365 lbs. of tobacco, 9,449 of wool, and 92,958 of butter. There were 2,247 horses, 2,161 milch cows, 4,041 other cattle, 5,557 sheep, and 22,486 swine. Jackson township is the temporary capital. **III.** A N. county of Kentucky, separated from Ohio and Indiana by the Ohio river; area, 300 sq. m.; pop. in 1870, 10,696, of whom 1,012 were colored. The surface is hilly and the soil fertile, resting upon a basis of blue limestone. The Louisville, Cincinnati, and Lexington railroad passes through the S. E. corner. The chief productions in 1870 were 38,424 bushels of wheat, 32,621 of rye, 770,505 of Indian corn, 86,441 of oats, 81,518 of potatoes, 279,740 lbs. of tobacco, 36,661 of wool, and 198,511 of butter. There were 4,709 horses, 2,918 milch cows, 5,580 other cattle, 11,278 sheep, and 31,466 swine. Capital, Burlington. **IV.** A central county of Indiana, drained by Eagle and Sugar creeks; area, 408 sq. m.; pop. in 1870, 22,593. The Indianapolis, Cincinnati, and Lafayette railroad passes through the centre of the county, and the Indianapolis, Bloomington, and Western through the S. W. corner. The surface is either level or moderately uneven, and the soil deep and fertile. The chief productions in 1870 were 888,352 bushels of wheat, 14,337 of rye, 749,482 of Indian corn, 52,075 of oats, 48,278 of potatoes, 68,607 lbs. of wool, 261,816 of butter, and 30,743 gallons of sorghum molasses. There were 7,902 horses, 5,147 milch cows, 8,648 other cattle, 23,095 sheep, and 27,109 swine. Capital, Lebanon. **V.** A N. county of Illinois, bordering on Wisconsin, intersected by Kishwaukee river; area, 270 sq. m.; pop. in 1870, 12,942. It has a rolling surface, diversified by fertile prairie lands and forests. The Kenosha, the Galena, and the Madison divisions of the Chicago and Northwestern railroad pass through the county; and there is also a branch railroad from Belvidere to Beloit. The chief productions in 1870 were 241,641 bushels of wheat, 35,871 of rye, 466,985 of Indian corn, 579,127 of oats, 52,355 of barley, 167,311 of potatoes, 31,323 tons of hay, 555,159 lbs. of butter, 17,810 of cheese, and 80,598 of wool. There were 6,309 horses, 7,088 milch cows, 7,966 other cattle, 20,810 sheep and 7,849 swine. Capital, Belvidere. **VI.** A central county of Iowa, watered by Des Moines and Snake rivers and Beaver creek; area, 576 sq. m.; pop. in 1870, 14,584. The Chicago and Northwestern railroad traverses the county, and the Des Moines valley line touches its S. W. corner. Forests occupy a considerable portion of the surface. The soil is highly productive. Coal is abundant. The chief productions in 1870 were 176,969 bushels of wheat, 727,831 of Indian corn, 151,272 of oats, 63,541 of potatoes, 22,019 tons of hay, 20,825 lbs. of wool, and 256,549 of butter. There

were 3,740 horses, 3,636 milch cows, 5,844 other cattle, 11,788 sheep, and 10,182 swine. Capital, Boonesboro. **VII.** A N. E. county of Missouri, bounded S. W. by the Missouri river; area, 648 sq. m.; pop. in 1870, 20,765, of whom 4,038 were colored. The Northern Missouri railroad and the Columbia branch pass through the county. The surface is slightly uneven, and consists mainly of prairies interspersed with forests. The soil is uniformly productive. Stone coal and limestone are the principal minerals. The chief productions in 1870 were 235,750 bushels of wheat, 1,096,114 of Indian corn, 260,019 of oats, 149,634 lbs. of tobacco, and 74,552 of wool. There were 7,218 horses, 2,709 mules and asses, 5,441 milch cows, 9,541 other cattle, 21,037 sheep, and 30,169 swine. Capital, Columbia.

BOONE, Daniel, an American pioneer, born in Bucks co., Penn., Feb. 11, 1735, died at Charette, Mo., Sept. 26, 1820. His father, Squire Boone, came from England and took up his residence in a frontier settlement in Pennsylvania, where Daniel received the merest rudiments of education, but became thoroughly familiar with the arts and hardships of pioneer life. When he was 18 years old the family moved to the banks of the river Yadkin in North Carolina, where he married Rebecca Bryan and passed some years as a farmer. He made several hunting excursions into the wilderness, and finally in 1769 set out with five others to explore the border region of Kentucky. They halted on the Red river, a branch of the Kentucky, where they hunted for several months. In December, 1769, Boone and a companion named Stewart were captured by the Indians, but escaped, and Boone was soon after joined by his brother. They were captured again, and Stewart was killed; but Boone escaped, and, his brother going shortly after to North Carolina, he was left alone for several weeks in the wilderness, with only his rifle for a means of support. He was rejoined by his brother, and they continued their explorations till March, 1771, when they returned home with the spoils which they had collected. In 1773 he sold his farm and set out with his family and two brothers and five other families to make his home in Kentucky. They were intercepted by Indians and forced to retreat to the Clinch river near the border of Virginia, where they remained for some time, Boone in the meanwhile conducting a party of surveyors into Kentucky for the governor of Virginia. He was afterward appointed, with the commission of a captain, to command three garrisons on the Ohio, to keep back the hostile Indians, and in 1775 was employed to lay out lands in Kentucky for the Transylvania company. He erected a stockade fort on the Kentucky river, which he called Boonesborough, and removed his family to the new settlement, where he was again employed in command of a force to repel the Indians. In 1778 he went to the Blue Licks to obtain salt for the settle-

ment, and was captured and taken to Detroit. His knowledge of the Indian character enabled him to gain favor with his captors, and he was adopted into one of their families. Discovering a plan laid by the British for an Indian attack upon Boonesborough, he contrived to escape and set out for the Kentucky settlement, which he reached in less than five days. His family, supposing that he was dead, had returned to North Carolina, but he at once put the garrison in order and successfully repelled the attack which was soon made. He was court-martialled for surrendering his party at the Licks, and for endeavoring to make a treaty with the Indians before the attack on the fort; but conducting his own defence, he was acquitted and promoted to the rank of major. In 1780 he brought his family back to Boonesborough, and continued to live there till 1792. At that time Kentucky was admitted into the Union as a state, and much litigation arose about the titles of settlers to their lands. Boone, losing all his possessions for want of a clear title, retired in disgust into the wilderness of Missouri, settling on the Femme Osage river, 45 m. W. of St. Louis, where he lived from 1795 to 1804. This region was then under the dominion of Spain, and he was appointed commandant of the Femme Osage district and received a large tract of land for his services, which he also lost subsequently because he failed to make his title good. His claim to another tract of land was confirmed by congress in 1812 in consideration of his eminent public services. The latter years of his life he spent in Missouri with his son-in-law Flanders Callaway. The only original portrait of Boone in existence was painted by Mr. Chester Harding in 1820, and now hangs in the state house of Kentucky. The remains of Boone and his wife were exhumed in 1845 and deposited with appropriate ceremonies in the cemetery of Frankfort, Ky. An account of Boone's adventures, as related by himself, was written out by John Filson (1784), and reprinted in the supplement to Finlay's "Description of the Western Territory" (1793). There is a life of Boone by John M. Peck in Sparks's "Library of American Biography." Lives of him have also been written by Timothy Flint, W. H. Bogart, and J. S. C. Abbott.

BOONE, William Jones, D. D., first missionary bishop of the Protestant Episcopal church at Shanghai, China, born in South Carolina, July 1, 1813, died at Shanghai, July 17, 1864. He graduated at the college of South Carolina, studied law under Chancellor De Saussure, and was admitted to the bar, but soon after studied for the ministry at the theological seminary of Virginia, and was ordained in 1835. During the following two years he studied medicine at the South Carolina medical college, and received his degree in 1837. Appointed early the same year a missionary to China, he sailed with his wife, and reached Batavia in October. He thenceforward devoted all his energies to the

acquisition of the Chinese language, and in time became one of the first scholars of modern times in that difficult tongue. In 1840 he removed to Macao for the benefit of his health, and two years later to Amoy, where his wife died in August, 1842. By desire of the foreign committee on missions, he returned to the United States in the summer of 1843, and was consecrated missionary bishop for China, Oct. 22, 1844. Taking with him several assistants, Bishop Boone reached Shanghai in June, 1845. He was especially occupied in translating the prayer book into Chinese, and, in connection with the missionaries from other denominations, in securing an accurate version of the Bible. It was in this work that his knowledge of the language was especially conspicuous. On two occasions, in 1852 and 1857, he returned home for the benefit of his health. Having succeeded in getting the mission to Japan under way, he returned to China in December, 1859. Severe domestic afflictions and other trials in connection with his mission, as well as incessant labors, soon broke down his feeble health and terminated his life.

BOONESBOROUGH, a decayed village of Madison co., Kentucky. In 1775 the first fort erected in Kentucky was built here by Daniel Boone. In Boonesborough was convened, toward the end of last century, the first legislative assembly ever held in the territories now forming the western states.

BOONTON, a town of Morris county, N. J., on the Rockaway river, at the terminus of a branch of the Morris and Essex railroad, and on the Morris canal, 40 m. N. W. of New York; pop. in 1870, 3,458. The town is situated in a mountainous region, the canal here overcoming a perpendicular elevation of 80 feet. The Delaware, Lackawanna, and Western railroad passes through it. The Boonton iron works, from which the place derives its chief importance, cover about 60 acres of ground, and include 14 large buildings, several offices and stores, and extensive sheds. Every branch of production is carried on, from the smelting of ores to the manufacture of the machinery and tools used in the establishment. There are two blast furnaces, which together produce about 450 tons of pig iron per week, the greater part of which is manufactured in the works. The proprietors own and operate the mines at Dover from which the ores are obtained. These are of the New Jersey magnetic variety, yield from 50 to 75 per cent. of iron, and contain but little sulphur. The product consists largely of gray and mottled iron of fine grain, available for both forge and foundry purposes. Connected with the blast furnace is a chemical laboratory, in which all the materials used are analyzed. The rolling mills contain 12 double puddling and 11 heating furnaces, and 6 trains of rolls. They produce chiefly the plate iron from which nails are cut, while of bar iron the production is limited to the requirements of the nut and bolt factory which forms a part of the establishment.

The two nail mills are the most important portion of the works, and contain 138 machines, which produce 100 kegs of nails an hour. About 300,000 kegs are used annually for packing the nails, and 20,000 for bolts and nuts, of which about 1,000 tons are produced annually. The keg mill connected with the establishment consumes yearly about 1,000,000 feet of heading stuff and 1,500 cords of stave timber. The only steam engines in the works are those which furnish the blast for the furnaces. The power that drives the machinery is furnished by the Morris canal, the water of which, after revolving a large overshot wheel in the nail factory, passes to the rolling mills, which have two large iron overshot wheels and four turbines, and thence into the canal again. In the old town of Boonetown, which was swept away early in the present century by the bursting of the dam across Rockaway river, was built in 1770 the first nail mill in the United States, which, notwithstanding opposition from the British authorities, was worked successfully for many years. There are no locks on the canal at this point, but the boats are transferred from one level to the other by means of an inclined plane 500 ft. long, upon which is laid a track of about 9 ft. gauge. The transfer is effected with great rapidity by means of an eight-wheeled cradle, capable of holding a canal boat, which is drawn along this track by a turbine wheel at the top of the incline. Boonton contains several churches and schools, and a weekly newspaper.

BOONVILLE, a city and the capital of Cooper co., Missouri, on the right bank of the Missouri river, 43 m. N. W. of Jefferson City; pop. in 1870, 3,506. It is situated in the midst of a rich farming region, in the vicinity of iron, lead, and coal mines, and of marble and limestone quarries. The grape is extensively cultivated. Boonville is the centre for most of the trade of S. W. Missouri, of a portion of Arkansas, and of the Cherokee nation. It has a court house, several churches, ropewalks, and four weekly newspapers, one of which is in German. It was settled by Daniel Boone.

BOORHANPOOR, or **Burhanpooor**, a town of British India, formerly capital of Candeish, in the territory of Gwalior, 180 m. S. S. E. of Oojein and 210 m. E. of Surat; lat. 21° 19' N., lon. 76° 18' E.; pop. about 20,000. It stands on the north bank of the Taptee, 60 or 70 feet above the stream, and is surrounded by a brick rampart in the form of a semicircle, in the centre of which is a palace of brick, called the Red Fort. It was built by Akbar, with pleasure gardens, halls of white marble, and a mosque; but it is now fast falling to ruin. The town itself contains but one edifice of much pretension, which is a mosque built by Aurungzebe. The streets are wide and regular, and many of the houses neat and commodious. The trade is almost monopolized by a Mohammedan tribe called the Borahs, who came originally from Arabia, and still retain the dress and

many of the customs of that country. They manufacture muslins, flowered silks, and brocades, and in the time of Tavernier (about 1665) used to export considerable quantities of their fabrics to Persia, Egypt, Turkey, Russia, and Poland, though even then Boorhanpoor had passed the meridian of its prosperity. The vicinity is noted for excellent grapes. This town was founded about 1414 by Malik Nasir, ruler of Candeish, and for a long time was the capital of the country. In 1599 it was besieged and taken by Akbar, king of Delhi, who reduced Candeish to a province of his empire. It was plundered by the Mahrattas in the reign of Aurungzebe in 1685, and in 1720 was wrested from the empire of Delhi by Azaf Jah or Nizam ul-Mulk, viceroy of the Deccan. It was subjugated by Madhajee Sindia in the latter part of the 18th century; was occupied by the British under Col. Stevenson in 1803, restored the same year, and finally with the whole of Sindia's territory, or Gwalior, passed under British protection in 1844.

BOORO, *Bouro*, or *Boeroe*, an island of the Malay archipelago between lat. 8° and 4° S., and lon. 126° and 127° E.; area, about 2,000 sq. m.; pop. 100,000. The surface is mountainous, the highest peak, Mount Donel, rising 10,400 feet; the soil is fertile, producing rice, sago, fruits, aromatic plants, and dyewoods. The island is well watered, and abounds with deer and babyrussa hogs. Fort Defence, on the E. side, is a Dutch station; on the north is Cajeli bay, where plentiful supplies can be obtained.

BOOTAN, or *Bhotan*, an independent territory of India, between lat. $26^{\circ} 30'$ and $28^{\circ} 30'$ N., and lon. $88^{\circ} 30'$ and 92° E., on the N. E. frontier of Bengal, among the Himalaya mountains, which separate it from Thibet on the N., and branch out over a great part of its surface. It is bounded E. by a region inhabited by savage mountain tribes, S. by the British districts of Assam and Goalpara, and the native state of Cooch-Bahar, and W. by the native state of Sikkim; length from E. to W., 215 m.; breadth, 115 m.; area, 19,130 sq. m. Some of the highest summits of the Himalaya chain lie on its N. border, from which the surface sinks by broken and abrupt descents to the Brahmapootra. The rivers are numerous, and have violent cataracts. The most important of them traverse the country from N. to S., and fall into the Brahmapootra. There are many bridges over the torrents, some of which are of very ingenious construction. In the lower part of the country the vegetation presents the usual features of the tropics; higher up are forests of pine, birch, maple, and yew, while the hills are covered with fruits common to Europe, such as apples, apricots, and berries. The soil in many places is well tilled. Rice, wheat, barley, turnips, gourds, and melons are raised in large quantities. The trade is chiefly with Bengal and Thibet; the exports comprise rice, wheat, flour, horses, linen, musk, and fruits; and the imports, cattle, hogs, dried fish, tobacco, cot-

ton, woollens, indigo, tea, gold, silver, and embroideries. Iron and copper are found, but not in large quantities. The inhabitants are tall, with smooth, dark skins, high cheek

Bootana.

bones, and the broad faces common to the Chinese and Tartars. Though courageous when attacked, they are by no means a warlike people, and have little knowledge of military art. They are industrious and devoted almost altogether to agriculture. The climate in the valleys at the foot of the Himalaya is very unhealthy. The religion is Buddhism, and there are many priests and monasteries, but morality is at a very low ebb. Polyandry and polygamy are both general, and no religious ceremony is observed in marriage. There are two sovereigns, one spiritual, called the *dhurma rajah*, and the other secular, known as the *deb rajah*. The chief towns are Tassisudon, Wandipoor, Poonakha, Ghassa, Paro, and Muri-chom; but for the most part the people live in small villages.—In ancient Brahmanical legends Bootan is called Madra. Up to the last century little is known with regard to its political condition. In 1772 the Booteahs ravaged the territory of Cooch-Bahar, whereupon the latter state applied to the British for assistance, which being granted, the rajah of Bootan was attacked within his own dominions, defeated, and forced to solicit aid from Thibet. By the mediation of the latter state, a treaty of peace was concluded in 1774. The British suffered severely for many years from the incursions of the Booteahs into the Dooars, a strip of fertile frontier country at the foot of the mountain passes leading from Bootan into Assam and Bengal. The Assam Dooars were occupied by the British in 1841, a rent being paid for them to the Bootan government. As

the depredations continued on the Bengal frontier, the Hon. Ashley Eden was sent as an ambassador to the two rajahs in 1863. He was violently maltreated on the route, and at the capital, Poonakha, and only allowed to return after signing on compulsion a treaty ceding the Assam Dooars. This treaty was at once repudiated by the British government, war was proclaimed (1864), and in a short campaign (1864-5) the forts commanding the passes were reduced, and the Dooars, 150 m. long and 30 to 40 m. wide, were annexed by treaty to the British possessions.

BOÖTES, in astronomy, a constellation in the northern hemisphere. The name is derived from the Greek *βοῦς*, an ox, and means an ox-driver. The modern figures represent Boötes as a man with a club in the right hand, and in the left the leash which holds two hunting dogs. It contains Arcturus, a star of the first magnitude.

BOOTH, Barton, an English actor, born in Lancashire in 1681, died in London, May 10, 1733. His father was a near relative of the earl of Warrington. The son ran away from the university of Cambridge and joined a company of strolling players. He appeared in Dublin in 1698 with great success in the character of Oronoko, and was afterward engaged at the Drury Lane theatre, London, under the management of Betterton. He was the favorite tragic actor of the day, gaining especial celebrity as Cato in Addison's play, and as the ghost in "Hamlet." He was highly esteemed for his attainments and character.

BOOTH, Sir Felix, an English manufacturer, born in 1775, died in 1850. He was head of the firm of Booth and company, distillers in London, and gave £20,000 in 1827 to aid the arctic expedition under Sir John Ross. For this public-spirited act he was made a baronet in 1834. Ross's expedition resulted in the discovery of the true position of the north magnetic pole, and of a large tract of country which was named Boothia Felix.

BOOTH. I. Junius Brutus, a tragedian, born in London, May 1, 1796, died on the passage from New Orleans to Cincinnati, Dec. 1, 1852. His father was a solicitor, his mother a descendant or relative of John Wilkes. He entered the navy at an early age, but soon changed from this to a printing office, afterward began the study of law, made some creditable attempts as a painter and sculptor, and finally went upon the stage, his first appearance being Dec. 13, 1813. After playing at minor theatres in England and on the continent, he made his début at Covent Garden theatre in October, 1815. He afterward played in provincial theatres, and having made a hit as Sir Giles Overreach, he was reëngaged at Covent Garden, where he appeared, Feb. 12, 1817, as Richard III. Edmund Kean, ten years his senior, had just made his appearance at Drury Lane theatre, the manager of which induced Booth to leave the rival house, and appear at his own on

the same nights with Kean. In "Othello" each took alternately the characters of Othello and Iago. This engagement was brief. Booth returned to Covent Garden, where he met with an unfriendly reception, but soon gained great favor, especially as Richard III., Sir Giles Overreach, and Lear. In 1820 he again appeared as leading actor at Drury Lane. He afterward went to Amsterdam, and then to Madeira, whence he suddenly sailed to America, arriving at Norfolk, Va., in July, 1821. His residence was thereafter in the United States, and for a period of 30 years he played in nearly every theatre in the country. In 1824 he purchased a farm at Belair, 20 m. from Baltimore, where he resided when not occupied by professional engagements. His range of characters was limited, embracing only those which he had studied in early life. Richard III., Iago, and Sir Giles Overreach were his favorite parts, although he excelled in Othello, Lear, Shylock, Hamlet, and Sir Edward Mortimer. His personifications were marked by an intensity which placed him in the first rank of tragedians, but his irregular habits very often interfered with his success. Notwithstanding this, he retained much of his vigor to the close of his life. **II. Edwin**, an American actor, son of the preceding, born at Belair, Md., in November, 1833. He was educated for the stage, supporting his father in inferior parts from his boyhood, and made his first regular appearance at the Boston museum in 1849 in a minor part in "Richard III." On occasion of his father's illness in 1851, he took his place and performed Richard III. at the Chatham street theatre, New York. In the following year he went to California and engaged for "utility business," and in 1854 made a visit to Australia, stopping at the Sandwich Islands on his way. He returned in 1857 and appeared at Burton's theatre, New York, in leading tragic parts. At the same theatre, under its new name of the Winter Garden, he gained a high reputation in 1860 for his delineation of Shakspearian characters. He visited England in 1861, appearing at the Haymarket theatre, London, and passed a year on the continent in studying his art. Returning to America in the fall of 1862, he entered upon a brilliant dramatic career, gaining great celebrity by his impersonation of Hamlet, Othello, Iago, Richard III., and other Shakspearian parts, and of Richelieu in Bulwer's drama of that name. In 1869 he built a theatre in New York, which has become celebrated for the presentation of standard dramas with great perfection of detail. **III. John Wilkes**, brother of the preceding, an actor and the assassin of Abraham Lincoln, born at Belair, Md., in 1839, died near Bowling Green, Va., April 26, 1865. He appeared on the stage at an early age, but with indifferent success. During the civil war he passionately sympathized with the South, and near its close entered into a conspiracy to assassinate President Lincoln, the vice presi-

dent, and some members of the cabinet. On the evening of April 14, 1865, the president was at the theatre in Washington. Booth gained access to his box, discharged a fatal pistol shot into the head of the president, and leaped upon the stage, breaking one of his legs. He reached the private entrance of the theatre, where a horse was in readiness for him, and with an accomplice rode 30 m. into Maryland. Here he stopped to have his fractured leg set by a physician, and then crossed the Potomac into Virginia. A party of pursuers overtook him before daybreak of the 26th at Garrett's farm, near Bowling Green, about 20 m. from Fredericksburg. He had taken refuge in a barn, and refusing to surrender, was shot, dying soon after. (See LINCOLN.)

BOOTHAUK, a fortified village of Afghanistan, 12 m. E. of Cabool, and at the commencement of a series of defiles between that place and Jelalabad. Here the Afghans made an attack upon the British army in January, 1842, during the disastrous retreat from Cabool, and literally annihilated it. The pass of Boothauk is 5 m. long, and in its narrowest parts, where it is but 50 ft. wide, is hemmed in by perpendicular cliffs 600 ft. high.

BOOTHBAY, a township of Lincoln co., Maine, on the coast, between the Damariscotta and Sheepscott rivers; pop. in 1870, 3,200. Its harbor is one of the best on the coast, and is never frozen over in the winter. The inhabitants are extensively engaged in ship building, the foreign and coasting trade, and the fisheries. Ferries connect the town with Bristol and with Southport, an island in the bay.

BOOTHIA FELIX, a peninsula forming the most northerly part of the North American continent, between lat. 69° and 75° N., and lon. 92° and 97° W. It is connected with the mainland by the isthmus of Boothia. It was discovered by Capt. James Ross, and named by him in honor of Sir Felix Booth. Ross here determined the position of the magnetic pole.

BOOTHIA GULF, a continuation to the southward of Prince Regent inlet, in British America. It separates Boothia Felix from Cockburn island and Melville peninsula, and is about 310 m. long and from 60 to 100 m. broad.

BOOTON, an island in the eastern archipelago, S. E. of Celebes, lat. 5° S., lon. 123° E., about 85 m. long by 20 m. wide. It is governed by its own prince; the inhabitants are Mohammedans. The island is mountainous and woody, but portions are well cultivated. There is a bay on the E. side of the island, into which in calm weather vessels are liable to be drawn by the current, which is so strong that once fairly in, it is said, they can only escape in the western monsoon. The Dutch East India company formerly maintained a settlement here.

BOPP, Franz, a German philologist, born at Mentz, Sept. 14, 1791, died in Berlin, Oct. 28, 1867. He began his studies at Aschaffenburg, went to Paris in 1812, and devoted several years to the study of the oriental languages

and literature, receiving encouragement and assistance from Chézy, Sylvestre de Sacy, and August Wilhelm von Schlegel. He afterward went to London to pursue his investigations, and finally passed some time at Göttingen, receiving a small pension from the king of Bavaria. On his return to Prussia in 1821 he was appointed professor of oriental languages in the university of Berlin, where he spent the remainder of his life. His first publication was a work on the Sanskrit verb, which was followed by a grammar and glossary of that language. He also published some Sanskrit poems and a portion of the epic *Mahabharata*, giving the original text with translations. The great work of his life, and one that may be said to have laid the foundation of the science of comparative philology, is his *Vergleichende Grammatik des Sanskrit, Zend, Griechischen, Lateinischen, Litauischen, Altslawischen, Gothischen und Deutschen* (5 vols., Berlin, 1833-'52; new ed., entirely recast and enlarged by the addition of the Armenian, 1857). A third edition was published after his death (1868-'71). In this work he traced back the Indo-European languages to their origin, and pointed out their present relations to each other. It has been translated into French and English. He wrote also on the relations of the Malayan and Polynesian languages to those of the Indo-European system, and on the Celtic, the Albanian, and the Caucasian languages. In honor of his memory the *Bopp-Stiftung* has been founded at Berlin, to promote the study of comparative philology. His library has been purchased by Cornell university, Ithaca, N. Y.

BOPPARD, or **Boppard** (anc. *Baudobrica* or *Bontobrica*), a walled town of Rhenish Prussia,

Boppard.

on the left bank of the Rhine, 9 m. S. of Coblenz; pop. in 1871, 4,977. It owed its origin to a fort supposed to have been built by Drusus. Its streets are narrow and antiquated,

and it contains two fine Gothic churches and two hydropathic establishments, one of which occupies the former abbey of Marienberg. The town has some trade and manufactories of cotton, tobacco, and leather.

BORA, *Katharina von*, the wife of Martin Luther, born at Löben, near Merseburg, Jan. 29, 1499, died at Torgau, Dec. 20, 1552. In her youth she was placed in the Cistercian convent of Nimptschen, near Grimma, in Saxony. Here she read some of the works of Luther, which inspired her with great enthusiasm, and she applied to him for aid in leaving the cloister. Through the instrumentality of Leonhard Koppe, a native of Torgau, Luther succeeded in securing the escape of Katharina and eight companions on the night of April 4, 1523. They fled first to Torgau, then to Wittenberg. As their parents refused to take them home, Luther provided for them as best he could. Some of them found employment as teachers, others married. Katharina became an inmate of the house of the burgomaster of Wittenberg, and on June 13, 1525, Luther married her. After his death she had the friendship and aid of Christian III., king of Denmark, and John Frederick of Saxony. She left three sons and two daughters.

BORACIC ACID. See BORIC ACID.

BORACITE, or *Borazite*, a mineral occurring in crystals imbedded in gypsum and anhydrite in Hanover, Holstein, and France; also impure in the salt mines of Stassfurt. It was formerly supposed to be composed of magnesium borate, but recent analyses have shown that it also contains chlorine. According to Potyka, a fair average sample has the following constitution:

Magnesia.....	26.19
Oxide of iron.....	1.66
Boric acid.....	61.19
Chloride of magnesium.....	10.41
Water.....	0.94

100.89

BORAGE (*borago*), a plant and the typical genus of the order *boraginaceæ*. Calyx 5, rarely 4-parted, and persistent; corolla hypogynous, monopetalous, rotate, 5, rarely 4-cleft, imbricate in æstivation; stamens inserted on the tube of the corolla, exserted, alternate with the segments of the corolla; anthers oblong or lanceolate, extrose, conniving in a cone around the style, awned; ovary 4-parted, carpels or nutlets 4, 1-seeded, 1-celled, distinct, seeds exalbuminous. Herbs or

Borage (*Borago officinalis*).

shrubs with alternate, exstipulate leaves, usually rough; flowers in spikes, panicles, or corymbs, rarely solitary in the axils. *B. officinalis* originally came from Aleppo, but is now thoroughly naturalized in central Europe and England. Corolla blue or purple, sometimes white, or with different colors on the same stem; tube of the corolla with emarginate rotate scales; nuts ovate-oblong, ribbed, the ribs denticulate. The plant was once in great repute, being reckoned one of the four cordial flowers, with alkanet, violets, and roses. A decoction of its leaves with honey was used as a pectoral medicine, and the drink called in England cool tankards is made of the succulent, mucilaginous stems. The juice contains much nitre, and to this is probably due the cooling quality of the plant. The young and tender leaves are used for pickles or as a salad, and hence borage is much cultivated in some cities of Europe.

BORAX (Arabic, *bûrak*), a salt first mentioned by Geber in the 10th century; its chemical nature was discovered by Geoffroy in 1732. It is largely prepared from the natural product boric acid, and is itself found native in various parts of the world. The anhydrous borax, or borate of sodium, has the formula $\text{Na}_2\text{B}_4\text{O}_7$, and is composed in 100 parts of boric anhydride (B_2O_3) 69.05, soda (Na_2O) 30.95. It is found native in some Alpine lakes, in the snowy mountains of India, China, and Persia, in Ceylon, and especially in the lake of Teshu-Lumbu in Great Thibet. This lake is distant 15 days' journey from a town of the same name, and it formerly furnished large quantities of borax. Is also occurs in still greater quantities near Potosi in Bolivia; in Pyramid lake, Washoe co., Nevada, and near Columbus, Esmeralda co., in the same state; also in Borax lake, California. The supply at the last named places seems to be inexhaustible. Formerly a large quantity of the borax formed by the spontaneous evaporation through the sun's heat of the waters of borax lakes, was imported into Europe under the name of *tincal*, *tincana*, *swaga*, or *pounxa*. It appears in small hexagonal crystals more or less flattened out, either colorless or having a yellowish or greenish tinge, with an earthy crust. It has a greasy feel, and smells like soap. The crude borax was first refined in Venice, where for a long time the process was kept a secret. Afterward it was also refined in Holland. At Lake Clear in California, 250 m. N. of San Francisco, where 4,000 lbs. of borax per day is produced, the muck which contains it is obtained by dredging, dried in the sun, and the borax dissolved out and crystallized.—The purification of tincal may be accomplished in various ways. The oldest method was to place it on a wire sieve or bolter and wash it with a lye containing 5 per cent. of soda so long as the liquor ran through colored. This removed all fatty substances that might adhere to it, forming a very soluble soap. After allowing the borax to drain, it is dissolved in boiling water, 12 per cent. of crystallized

carbonate of soda added, and the solution filtered. It is then evaporated to the specific gravity of 18° to 20° B., and allowed to crystallize in wooden vessels well lined with lead. In order to obtain single, well formed crystals, and to prevent a crust forming, the liquor must cool very slowly. Another process consists in pouring over the tincal a small quantity of cold water, and gradually adding, while stirring, 1 per cent. of caustic lime. Some time after boiling water is added and the liquor strained. The greasy substances that contaminated the tincal remain behind as an insoluble lime soap. Two per cent. chloride of calcium is added, and it is again strained and allowed to crystallize. Clouet reduces the tincal to a fine powder, mixes with 10 per cent. of nitrate of sodium, and calcines the mixture in an iron pan over a gentle fire, thus burning out all the fatty matter. The calcined mass is then dissolved in water, the solution separated from the carbon left behind, evaporated, and the crude borax crystallized out. Its varying crystalline form depending on the amount of water it contains, borax is divided into (1) the common or prismatic (natural or artificial), and (2) the octahedral, containing but half as much water of crystallization. Prismatic borax ($\text{Na}_2\text{B}_4\text{O}_7 + 10\text{H}_2\text{O}$) consists in 100 parts of boric acid 36.6 , soda 16.2 , water of crystallization 47.2 . Octahedral borax ($\text{Na}_2\text{B}_4\text{O}_7 + 5\text{H}_2\text{O}$) contains boric acid and soda 69.36 , water of crystallization 30.64 .—Prismatic borax is made as follows: About 26 cwt. of sal soda is dissolved in 400 gallons of water, placed in a large tightly closed vat lined with lead. The solution is caused to boil by a jet of steam entering it. About 24 cwt. of crude boric acid is introduced, in portions of 9 or 10 lbs. at a time, through a tube dipping under the surface of the liquor. A discharge pipe conducts off the carbonic acid, together with some carbonate of ammonia formed at the same time, the ammonia being retained by passing it through dilute sulphuric acid. The solution is brought to a density of 21° to 22° B. by the addition of either crude borax or water as may be required. The solution is allowed to settle and drawn off into the crystallizing vessels, also lined with lead, and left two or three days, the crystals placed on an inclined plane to drain, and then recrystallized, the mother liquor being used to dissolve a fresh quantity of soda. After using this mother liquor three or four times, it contains sufficient Glauber's salt for it to crystallize out, when cooled below 33° C., at which point it is most soluble. The crude borax is purified by recrystallization, 5 per cent. of carbonate of sodium being added to the solution. To obtain large crystals the crystallizing vessels are surrounded by some non-conductor, usually wool, and thickly covered. In the English factories borax is made by fusing the crude boric acid with one half its weight of calcined soda on the hearth of a muffle furnace, under continual

stirring. The ammonia, existing in crude boric acid as sulphate, goes off in the form of carbonate, and is condensed in a suitable chamber. The fused mass is dissolved in hot water, clarified by allowing it to settle, and cooled slowly in an iron vessel. In France its manufacture has been united with that of fuming sulphuric acid; the boric acid and calcined Glauber's salt being distilled together, and borax obtained from the residue left in the retort.—Very recently borax has been obtained from the native borate of lime and soda (tiza or boronatrocalcite), which is found in Tarapaca in Peru, and on the W. coast of Africa. The mineral is ground and triturated, then covered with two thirds its own weight of commercial hydrochloric acid, and to this double its volume of water added, and digested at a boiling heat until entirely decomposed, the heat being increased toward the close and water added to preserve the original volume. It is allowed to settle, and decanted while hot. On cooling, nearly all the boric acid crystallizes out, leaving the chloride of sodium and chloride of calcium, together with a slight excess of hydrochloric acid, in the mother liquor. The boric acid thus obtained is allowed to drain, pressed or squeezed out, washed in cold water, and again dried, when it is so pure that on adding soda a pure borax is obtained on the first crystallization. In England the boronatrocalcite is fluxed with soda, but the process offers many difficulties. The use of stassfurtite to make borax has also been successfully tried in Germany. Prismatic borax forms almost colorless, transparent crystals, of a specific gravity 1.75 , soluble in 12 parts cold water or 2 parts of boiling water; the solution is slightly alkaline. Exposed to the air, the crystals effloresce only on the surface; on being warmed they decrepitate, and swell up into a spongy mass known as calcined borax; at a red heat they fuse to a transparent glass (borax glass), which takes up water and loses its transparency very slowly.—Octahedral borax ($\text{Na}_2\text{B}_4\text{O}_7 + 5\text{H}_2\text{O}$) is prepared as follows: A boiling solution of prismatic borax is made of a specific gravity of $1.26 = 30^{\circ}$ B., and allowed to cool slowly and regularly. The octahedral crystals begin to form at 79° C., and continue to do so down to 56° , below which temperature the mother liquor produces only prismatic crystals, and hence must be removed. Buran obtained them from a solution of a specific gravity of 32° B., ten days being allowed for 10 cwt. to cool. The tincal from India and half-refined borax from China are sometimes octahedral. It differs from the ordinary borax in crystalline form, has a specific gravity of 1.81 , is hard enough to scratch a prismatic crystal, and when exposed to moist air becomes opaque, takes up water, and goes back into the prismatic form.—The uses of borax are numerous. It has the property at a high temperature of dissolving metallic oxides, and forming transparent glasses, the color depending on the

metal used; thus cobalt oxide gives a blue glass, chromium oxide a green glass, and so on. On this property depends its use not only in analytical chemistry, where it serves to determine certain metals before the blowpipe, but also in soldering. Borax is largely used in making strass, enamels, and some kinds of glass, and in vitreous pigments for glass and porcelain; in glazing earthenware; as a flux to reduce certain metals from their ores; and in South America, under the name of *quemason*, the crude substance is actually used in smelting copper. With shellac (in the proportions 1 to 5) it forms a varnish soluble in water, used in stiffening felt hats. With casein it makes an adhesive substance that may be used instead of gum arabic. Borax is used instead of soap for washing the gum out of silk, instead of sal soda in the laundry, to cleanse the hair, and as a cosmetic. In printing and dyeing establishments it has been proposed to use it to fix the mineral mordants. Aqueous borax has been proposed as an agent for the preservation of wood. In medicine it is employed for many diseases connected with the bladder and the uterus, and also as a wash for cutaneous eruptions, canker in the mouth, and ringworm. It has the property of making cream of tartar, when boiled together with it, very soluble in water, and this soluble cream of tartar is often found a convenient preparation when large doses of this medicine are required. It is also used to expel cockroaches from closets and pantries, these insects seeming to have an antipathy for it.

BORBECK, a town of Rhenish Prussia, on the Ruhr, 4 m. N. W. of Essen; pop. in 1871, 16,857. It has a castle, and is the seat of a flourishing iron industry; in the vicinity are several coal mines. The place is rapidly increasing in population.

BORDA, *Jean Charles*, a French mathematician, born at Dax, May 4, 1733, died in Paris, Feb. 20, 1799. He served as a young man both in the army and navy, and gave much study to the principles of projectiles and the construction of vessels. Chosen a member of the academy in 1756, he furnished to it several valuable contributions on these subjects. He was employed by the government in 1771 on expeditions to ascertain the value of chronometers in determining longitudes. He was sent on several geographical expeditions, and was one of the commissioners with Delambre and Méchain to determine the arc of a meridian as the basis of the metrical system of measures and weights. A new instrument for measuring the inclination of the magnetic needle was invented by him, and he made important improvements in the reflecting circle for the accurate measurement of angles. He rose to the rank of major general of marines, serving as such in the American war of independence. He wrote several works on mathematics and navigation, and constructed logarithmic tables for the centesimal division of the quadrant.

BORDE, *Andrew*, an English physician, born at Pevensey, Sussex, about 1500, died in London in April, 1549. He travelled in various parts of Europe and Africa, and finally settled down as a physician in England. It is said that he became fellow of the college of physicians in London, but he died insolvent in the Fleet prison. He wrote several works of a humorous character, and is said to have given rise to the phrase "merry Andrew," from his practice of making droll speeches at fairs and public gatherings, to attract the people.

BORDEAUX (anc. *Burdigala*), a city and seaport of France, capital of the department of Gironde, on the left bank of the river Garonne, 58 m. from its mouth, and 307 m. S. W. of Paris; pop. in 1866, 194,241. Long before the Christian era *Burdigala* was a commercial emporium, and the chief town of the *Bituriges Vivisci*, a Celtic nation of southern Gaul. In the 2d century Hadrian made it the metropolis of *Aquitania Secunda*. During the decline and after the fall of the Roman empire it suffered successively at the hands of the Goths, Vandals, Saracens, and Normans. It was annexed to the Frankish kingdom by Clovis, and reconquered from the Saracens by Charles Martel. On the final dissolution of the Carlovingian empire it became the capital of the duchy of Aquitaine. Eleanor of Aquitaine united it to France by her marriage with Louis VII.; but after her divorce she married Henry Plantagenet, afterward king of England (1154), thus subjecting the duchy to the English crown. From that period until the middle of the 15th century Bordeaux remained in the possession of the English, and in the 14th century the Black Prince made it the seat of his court. The city was the last to submit to Charles VII. of France, in 1458. Since that time the city has been substantially rebuilt, and now is architecturally one of the finest in Europe. In the first revolution it was the headquarters of the Girondists, and suffered much during the reign of terror. Under Napoleon it was injured by the continental blockade, and toward the close of his reign became noted for its loyalty to Louis XVIII. In December, 1870, the delegation of the provisional government of France, consisting of Gambetta, Glais-Bizoin, and Crémieux, which during the first months of the siege of Paris had governed the provinces from Tours, established itself at Bordeaux; and on Feb. 12, 1871, the national assembly of the French republic met there, removing to Versailles in March.—Besides the palace or amphitheatre of Gallienus, very few remains of the Roman monuments are to be seen. Those of the middle ages have been better preserved; among these are the cathedral of St. André, an imposing though irregular Gothic edifice, consecrated in 1096 and completed in the 15th century; the church of St. Michel, built about the 12th century; the church of Ste. Croix, built before the middle of the 7th century, and restored by Charlemagne; the imperial college,

Bordeaux.

and other ancient buildings. The modern aspect is admirable. The broad curve of the Garonne is lined with crowded quays, adjacent to which are some of the most commodious warehouses in Europe. The bridge which connects the city with the suburb La Bastide was completed in 1821, at a cost of \$1,300,000; it is 1,590 ft. long, with 17 arches. Two of the old gates of the city still remain, la porte du Palais, formerly the entrance to the palace of the dukes of Aquitaine and the seneschals of England, and la porte de l'Hôtel de Ville, which is surmounted by three antique turrets. There are numerous open squares, broad avenues, and fine promenades. The place des Quinconces is the finest square in the city, and occupies the site of the ancient château Trompette. The public garden in the same neighborhood is elegantly laid out with conservatories, &c. Among the finest of the modern edifices of the city are the Grand theatre, erected in 1780, at a great expense, and presenting one of the handsomest exteriors in Europe; the bourse, in which the merchants congregate daily under a glass dome covering an inner court 95 ft. long by 65 broad; the palais de justice and the hôtel de ville, formerly the palace of the archbishop. There are several fine churches besides the mediæval ones already mentioned, among them St. Michel, which has a lofty detached tower and contains some fine works of art, and St. Seurin, remarkable for its finely carved porch and curious bass reliefs. There are also a gallery of paintings, a museum containing many historical relics, a museum of natural history, and a public library with 140,000 volumes. The imperial college, academy of arts, sciences, and belles-lettres, and the botanical garden with courses of study and lectures, are among the learned institutions; and there are numerous schools and

educational associations.—In commercial importance, wealth, and culture, Bordeaux is excelled by no French city except Paris. The harbor is commodious, and always crowded with shipping from America, Great Britain, and the Mediterranean ports, and the entrance and channel of the river have been greatly improved in recent years. Ship building is very extensively carried on, but the city is not distinguished for general manufactures. There

Grand Theatre.

are some iron foundries, cotton factories, and sugar refineries; and brandy, vinegar, cordage, gloves, and musical instruments are made. There is but one bank in the city, and that was transformed in 1848 into a branch of the bank of France. In 1864 1,488 vessels of 356,565 tons entered the port, of which 732 of 142,947 tons were French; and 1,455 vessels of 375,291 tons left it, of which 707 of 167,145 tons were French. The same year 1,644 French coasting

vessels of 129,762 tons entered, and 1,745 of 116,714 tons cleared. The red and white wines of the Gironde are exported almost altogether from Bordeaux. The average annual export from 1860 to 1865 was 18,861,976 gallons, of which 5,600,127 went to European ports, 1,822,362 to the United States, and the rest to other countries. The brandies exported from Bordeaux are produced mainly in the districts of Armagnac and Marmande. The principal distilleries are at Cognac, the best known being those of Martell and Hennessy. The average annual exportation from 1860 to 1864 was 1,598,211 gallons, of which 413,900 gallons went to European ports, 445,329 gallons to the United States, and the rest to other countries.

BORDEAUX, Duke of. See CHAMBORED.

BORDEAUX WINES. See FRANCE, WINES OF.

BORDELAIS, a district of S. W. France, in the ancient province of Guienne, now forming a part of the department of the Gironde. The inhabitants of Bordeaux and its neighborhood are called the Bordelais; and the same term is applied to the products of the district, of which wine and a breed of cattle resembling those of Holland are the principal.

BORDEN, Simeon, an American engineer and mechanic, born at Fall River, Mass., Jan. 29, 1798, died there, Oct. 28, 1856. With very little instruction he mastered the principles of mathematics and mechanical science, and became a skilful engineer and one of the best mechanics of his day. In 1828 he took charge of a machine shop in Fall River, and in 1830 devised and constructed for the state of Massachusetts an apparatus for measuring the base line of the trigonometrical survey of that state, which at that time was the most accurate and convenient instrument of the kind extant. Mr. Borden assisted in the measurement of the base and in the subsequent triangulation. In 1834 he took charge of the work, and completed it in 1841. It was the first geodetic survey ever completed in this country, and its precision has since been proved by the coast survey. He afterward laid down the boundary lines between Massachusetts and Rhode Island, constructed several railroads, and published in 1851 a volume entitled "A System of Useful Formulæ, adapted to the Practical Operations of Locating and Constructing Railroads." In 1851 he accomplished a difficult feat by suspending a telegraph wire over a mile long, upon masts 220 ft. high, across the Hudson, from the Palisades to Fort Washington.

BORDENTOWN, a township and village of Burlington county, New Jersey, on the Camden and Amboy railroad, 6 m. S. E. of Trenton; pop. of the township in 1871, 6,041. The village lies pleasantly on an elevated plain on the left bank of the Delaware river, and contains several public and private schools. It is the terminus of the Delaware and Raritan canal, is connected by railroad with Trenton, and is a favorite place for excursions by steam-

boat from Philadelphia. The extensive car shops, locomotive works, and general depot of supplies of the Camden and Amboy railroad are situated here. The mansion built by Joseph Bonaparte is in the neighborhood.

BORDLEY, John Beale, an American agriculturist, born in 1728, died in Philadelphia, Jan. 25, 1804. He was a lawyer who devoted himself to husbandry, and cultivated an estate on Wye island in Chesapeake bay. He published many essays and short treatises on agricultural topics, and established at Philadelphia in 1793 the first agricultural society in the United States.

BORDONE, Paride, a painter of the Venetian school, born at Treviso about 1500, died in Venice about 1570. He was for a time a pupil of Titian, and afterward studied the works of Giorgione. His own style, though not an imitation, is formed in a measure on the characteristics of these two artists. He attained special celebrity for his portraits. Several of his pictures are to be found in the galleries of Venice, including his masterpiece, the "Old Gondolier presenting a Ring to the Doge."

BORE, the rapid rushing of the tide inland against the current of a river. This phenomenon takes place when a narrow river falls into a gradually widening estuary subject to high tides. At spring tides the great volume of water which enters the wide mouth of the estuary is compressed as it advances till it is several feet higher than the mouth of the river, up which it therefore rushes like a torrent. In England the bore is observed in the Severn and Trent rivers and in Solway frith. There is a remarkable bore in the Hoogly branch of the Ganges, where the current goes 70 m. in 4 hours; also at the mouth of the Brahmapootra, where no boat ventures to navigate at spring tide, and at the mouth of the Indus. The rise of the tide in the bay of Fundy resembles a bore, and this phenomenon occurs in some of the smaller rivers on the coast of Brazil, as well as in the Amazon on a large scale.

Boreas. (From a base relief on the Temple of the Winds, Athens.)

BOREAS, the Greek name of the north wind; in mythology, son of Astræus and Eos (Aurora),

and brother of Hesperus, Zephyrus, and Notus, dwelling in a cave of Mount Hæmus in Thrace. He carried off Orithyia, daughter of Erechtheus, by whom he begot Zetes, Calais, and Cleopatra, who are called Boreades. In the Persian war Boreas destroyed the ships of the invaders, and hence was worshipped at Athens, where a festival, Boreasmi, was instituted in his honor. He was represented with wings, which, as well as his hair and beard, were full of flakes of snow; instead of feet he had the tails of serpents, and with the train of his garment he stirred up clouds of dust.

BORECOLE, a variety of cabbage, known also as kale and German greens, celebrated for tenderness and delicate flavor. Wild cabbage, or *brassica oleracea*, to which species borecole belongs, is met with in abundance in many parts of Europe. It is very common in the southern

Borecole.

part of Turkey, especially about Mount Athos. It is also found in Great Britain, on the coast of Kent, near Dover, on the Yorkshire coasts, in Cornwall and Wales, and on the Isle of Wight. In other places it forms a broad-leaved glaucous plant, with a somewhat woody stem, having but little likeness to its cultivated progeny.

BORELLI, Giovanni Alfonso, an Italian mathematician and physician, born at Castelnuovo, near Naples, Jan. 28, 1668, died in Rome, Dec. 31, 1679. He was professor of mathematics in Messina and in Pisa, became in Rome a favorite of Queen Christina of Sweden, taught mathematics (1677-'9) at the convent of St. Pantaleon, and was a member of the *accademia del Cimento*. He was one of the leaders of the iatro-mathematical school, and employed himself diligently in the dissection of animals with a view of explaining their functions upon mathematical principles. He invented a diving apparatus, excelled as an astronomer, wrote extensively on medicine, mathematics, and astronomy, and also published a scientific account of the eruption of Mt. Etna (1669). The first part of his principal work, *De Motu Animalium* (2 vols., Rome, 1680-'81), skilfully applies the principles of mechanics to the exposition of the movements of the body; but the second part is regarded as fallacious in respect to the application of mechanical principles to the ac-

tion of the heart, lungs, liver, and other viscera. This work was long regarded as a standard authority by the iatro-mathematical school.

BORGERHOUT, a town of Belgium, in the province and 3 m. E. of Antwerp; pop. in 1866, 10,787. It is well built, and has bleaching and dyeing works, and manufactures of woollen goods and tobacco.

BORGET, Auguste, a French painter, born at Issoudun, Aug. 30, 1808. He studied under eminent masters, and in 1836 produced his first work, the "Banks of the Tiber." He made a journey round the world, and published illustrated albums of his travels, including *La Chine et les Chinois* (1842), and *Fragments d'un voyage autour du monde* (1845-'6). He also executed over 200 designs for *La Chine ouverte*, by Old-Nick (1845), and contributed to illustrated journals. He has painted many genre pictures and landscapes on Chinese, Hindoo, and other foreign subjects.

BORGHESE, the name of a patrician family of Siena, Tuscany, which came into prominence about the middle of the 15th century. Marco Antonio Borghese settled in Rome in the early part of the 16th century, and became an advocate of the papal court. His third son, Camillo, became Pope Paul V. in 1605, and did much for the advancement of his relatives. For Marco Antonio, a son of his elder brother, he procured the principedom of Sulmona and a grandeeship in Spain. His own brother Francesco he made commander of the troops which he sent against Venice in 1607. Scipione Caffarelli, a nephew, he created cardinal. Paolo, the son of Marco Antonio, married Olimpia Aldobrandini, the only child of the prince of Rossano, and grand-niece of Clement VIII., who brought the wealth of the Aldobrandini into the Borghese family. The son of Paolo, Giovanni Battista, was the ambassador of Philip V. to the court of Rome, where he died in 1717. His son, Marco Antonio, was viceroy of Naples in 1721, and another of the same name, descended from him, became a noted collector of works of art, with which he adorned his sumptuous villa near the Pincian hill.—**CAMILLO FILIPPO LUDOVICO**, son of the art collector, born in Rome, July 19, 1775, died at Florence, April 10, 1832. He joined the French on their invasion of Italy and went to Paris, where in 1803 he married Marie Pauline, sister of Napoleon and widow of Gen. Leclerc. (See **BONAPARTE**.) In 1804 he was made a prince of the empire and received the grand cross of the legion of honor. He served in the Austrian war of 1805, and at its close received the title of duke of Guastalla, the duchy itself being bestowed on his wife. He took part also in the campaign of 1806-'7 against the Prussians and Russians; but not long after, becoming jealous of his wife, he separated from her and retired to Florence. He was, nevertheless, after the peace of Tilsit in 1807, appointed by the emperor governor general of the provinces beyond the Alps, which included

the former states of Piedmont and Genoa. At the request of Napoleon he sold to the French nation, for the sum of 8,000,000 francs, over 300 of the works of art which ornamented the palace of his ancestors at Rome. After the abdication of the emperor he broke off all connection with the Bonapartes, and fixed his residence in Florence, where he lived in great splendor till his death. He was reconciled to his wife shortly before her death in 1825. Besides the famous villa near the Pincian hill, his family had large estates in Tuscany, Naples, and the papal territories.

BORGHESI, Bartolommeo, count, an Italian numismatist, born at Savignano, near Rimini, July 11, 1781, died at San Marino, April 10, 1860. His father was a man of considerable learning, and had made a large collection of coins, to which the son made valuable additions. He pursued the study of numismatics as a branch of historical research, published in 1820 the "New Fragments of the Consular Fasti of the Capitol" (*Nuovi frammenti dei Fasti consolari capitolini illustrati*), and intended to publish a *Corpus Universale Inscriptionum Latinarum*. This he never accomplished, but his correspondence and contributions to various Italian journals form an immense mass of material, and after his death Napoleon III. appointed a commission to collect and publish his complete works. In 1864 appeared vols. i. and ii. of *Œuvres numismatiques*, and vol. i. of *Œuvres épigraphiques*. Two additional volumes were published in 1872.

BORGHI-MAMO, Adelaide, an Italian opera singer, born in Bologna, Aug. 9, 1830. She made her début at Bologna in December, 1846, and has since sung in the leading cities of Europe with great success. Her voice is a contralto of remarkable compass and power.

BORGI, Giovanni, the founder of ragged schools, born in Rome about 1736, died about 1802. He was a poor mechanic, but was in the habit of taking home the vagrant children of the streets, clothing them, and apprenticing them to various trades. His zeal interested others in the work, and he obtained means to rent a suitable building and to pay the expense of teaching and providing for a large number of poor children. The institution outlived Borgi, and was greatly extended, Pius VII. becoming its principal protector.

BORGIA. I. Cesare, an Italian prelate and soldier, born about 1457, died March 12, 1507. His family was of Spanish origin, but attained considerable prominence at Rome after the elevation of Alfonso Borgia to the papal throne in 1455 as Calixtus III. His father was Pope Alexander VI., and his mother a woman called Rosa Vanozza (Giulia Farnese). He was bishop of Pampeluna when a mere youth, and soon after his father's accession was made archbishop of Valencia, and in 1493 a cardinal. He began a war of extermination against the feudal barons and small princes in the Papal States and its vicinity, having persuaded his

father to take the lead in this movement. They dispossessed most of the feudatories, seizing their strongholds, castles, and estates. He is believed to have poisoned Zizim, the brother of Bajazet II., who sought refuge in Rome about this time. He also poisoned Giovanni Battista Ferrata, the richest and most influential dignitary in the papal court, and seized the treasures he had accumulated. Soon afterward he was suspected of procuring the murder of his own brother, Giovanni Borgia, duke of Gandia, who was found in the Tiber pierced with nine stiletto strokes by unknown hands. At all events he obtained his duchy and other possessions. In 1497 the pope released him from his clerical vows, and endeavored to make him marry Charlotte, daughter of Frederick of Aragon, king of Naples. This scheme, however, was unsuccessful, but a cardinal who participated in the intrigue was poisoned and his fortune seized by Borgia. Cesare was sent to France the next year with the bull divorcing Louis XII. from his wife Jeanne, and was rewarded by Louis with the dukedom of Valentinois and a command in the French army. While in the French service he obtained possession of Forlì, Cesena, Imola, Rimini, Piombino, the island of Elba, Faenza, and Camerino, and murdered their sovereigns. He married Charlotte, daughter of Jean d'Albret, king of Navarre, in 1499, and in 1501 he was made duke of Romagna and gonfaloniere of the holy see. He continued his onslaught on the petty sovereigns of central Italy, and aimed at making himself king of Romagna, Umbria, and the Marches; but Louis XII. arrested these ambitious machinations, and many whom Cesare had already deprived of their possessions recovered them. His most bloody military action was the storming of Sinigaglia, toward the close of 1502, at the head of his Swiss mercenaries, and the slaughter of his prisoners, including several princes, as described by Machiavelli. Finally, as many historians allege, in conjunction with his father, in August, 1503, he concocted the plan of poisoning four of the wealthiest cardinals at an evening party in the villa Corneto; but by mistake the poison, which was mixed in wine, was administered to Alexander VI. and to Cesare. The pope died about a week after. Cesare was saved, having taken but little of the drugged wine. He seized upon the papal treasures in the Vatican, and with about 12,000 mercenaries still kept Rome, although those whom he had despoiled in central Italy revolted and recovered their lost property. Finally his troops abandoned him, and the pope, Julius II., arrested and expelled him from the Papal States. He took refuge with Gonsalvo de Cordova, the commander of Naples, who sent him to Spain, where he was imprisoned by Ferdinand of Aragon. After two years he escaped and found an asylum, in 1506, at the court of Jean d'Albret, his father-in-law. Finally he was slain before the castle of Viana, while in the

service of the king of Navarre. He was highly educated, eloquent, and a patron of art and literature. For this reason he found many apologists, among them Machiavelli, who took him as the model ruler in his *Principe*. **II.** *Lucrezia*, sister of the preceding, died in 1528. She was equally remarkable for beauty and accomplishments, and was in her youth affianced to a nobleman of Aragon, but her father on becoming pope married her to Giovanni Sforza, lord of Pesaro. This union was dissolved in 1497, and she was given in marriage to Alfonso, duke of Bisceglia, natural son of Alfonso II, king of Naples, and made duchess of Spoleto and Sermoneta. The duke was assassinated two years later, as was believed by order of her brother Cesare. In 1501 she married Alfonso d'Este, son of the duke of Ferrara, became a patron of men of letters, and attracted a brilliant society to her court. In her later years she was much given to devotion and acts of charity. She has been often represented as a monster of profligacy, sharing in the atrocities of her father and brother, and even living with them at Rome in incestuous intercourse; but she has also found many defenders, who deny the crimes alleged against her.

BORGIA, St. Francis, general of the society of Jesus, born at Gandia, Spain, in 1510, died in Rome, Oct. 1, 1572. He was duke of Gandia, grand equerry to Isabella of Portugal, the consort of Charles V., and *mayor domo* to the crown prince, afterward Philip II. He was always exact in his religious duties, and after the death of his wife gave up his title and estate to his son and entered the society of Jesus, retaining the administration of the duchy, by special permission of the pope, until his children were provided for. He was ordained priest in the 40th year of his age, and devoted himself to extending and strengthening the order of Jesuits in Spain. At the death of Laynez in 1565 he was elected general of the society, and remained in office till his death. Several bishoprics and the dignity of cardinal were repeatedly pressed upon him, but refused. He was canonized by Clement X. in 1671.

BORGIA, Stefano, an Italian cardinal and statesman, born at Velletri, Dec. 3, 1731, died in Lyons, Nov. 23, 1804. He was a generous patron of science, and made valuable collections of manuscripts, coins, and various antiquities. Having been made a member of the Etruscan academy of Cortona in 1750, he founded the celebrated museum of antiquities at Velletri. He was for some years governor of the duchy of Benevento, and by his sagacity preserved that province from the famine which ravaged the kingdom of Naples in 1764. In 1770 he became secretary of the propaganda, and during 18 years that he occupied that office was enabled greatly to enrich his collection of rare manuscripts and antiquities through the missionaries. Pius VI. named him a cardinal in 1789, and put under his care the institution of foundlings, and in 1797, when the

revolutionary movement reached Rome, made him dictator of the city. Expelled by the Roman republicans, he retired to Venice, and afterward to Pisa, where he formed a small society of scientific men. He returned to Rome with Pius VII. in 1800, and devoted himself to reorganizing the papal government. He died while on a journey to Paris as companion of the pope. Besides his valuable collections, he left several historical works of some merit.

BORGNE, Lake, a body of water in the S. E. part of Louisiana. It is strictly the termination of that large arm of the Mexican gulf known as Mississippi sound, being connected with it by a strait crossed by a line of small islands, and faced on the east by Grand island. It is also connected with Lake Pontchartrain by the Rigolet pass. It has about the average depth of Lake Pontchartrain, and approaches within 15 m. of New Orleans. Its greatest extent from N. E. to S. W. is about 27 m. Lake Borgne forms a part of the eastern boundary of the Mississippi delta.

BORGGO, Pozzo di. See Pozzo di Borgo.

BORGOGNONE, Jacopo Cortesi, also known as JACQUES COUERTOIS (his original name), an Italian painter, born in Burgundy in 1621, died in Rome, Nov. 14, 1676. He studied his art at Bologna, a part of the time under the instruction of Guido. He worked very rapidly, and excelled in representing battle scenes. For many years he resided at Florence, where he acquired a fortune by his pencil, and about 1656 became a Jesuit, still devoting himself to art, but working chiefly on religious subjects.

BORGOMANERO, a walled town of Piedmont, Italy, in the province and 20 m. N. N. W. of the city of Novara, beautifully situated near the Agogna and on the road to Lakes Orta and Maggiore; pop. about 7,000. The town contains several churches, convents, and other public buildings, and manufactories of silk and several other articles.

BORGOO. I. A kingdom in the interior of Africa, bounded N. by Goorma, E. by the Niger, S. by Yoruba, and W. by Dagomba. It is generally a level country, though crossed by a range of mountains. The soil is fertile and well cultivated, and produces corn, yams, plantains, and limes. Game is found in abundance. The people are good-natured, and tolerably honest and thrifty. Borgoo is divided into the states of Boossa, Wawa, Kiama, and others, and is crossed by a caravan route over which there is considerable traffic. Boossa, which holds the first rank among the states, was the scene of the murder of Mungo Park. **II.** Another kingdom in the interior of Africa, about 400 m. N. E. of Lake Tchad. It is a mountainous region, and is said to be fertile and healthy. It has never been explored by Europeans. An unsuccessful attempt was made to reach it by Barth and Overweg in 1851.

BORIC ACID, a compound of the element boron with oxygen and hydrogen; also called boracic acid. It occurs in nature under the

name of sassoline, H_2BO_3 , composed of boric anhydride, B_2O_3 , 56.45 per cent., and water 43.55. It is also contained in the following minerals, in the proportions given: boracite (magnesium chloride and borate), 62.5 per cent.; rhodocite (calcium borate), 30 to 45; tiza or boronatrocalcite, 30 to 44; hydroboracite, 47; borax or tincal, 36.53; datholite (boro-silicate), 18; botryolite (do.), 20.35; axinite (do.), 2 to 6.6; tourmaline, schorl (do.), 2 to 11.8; larderellite (ammonium borate), 68; lagonite (iron borate), 49; also in many mineral waters and the ocean. Boric acid is the hydrate of boric oxide, also called boric anhydride, B_2O_3 . It was discovered in 1702 by Homberg, who called it sedative salt. The crystals are white, pearly, and scaly, unctuous to the touch, and exposed to a temperature of 212° F. lose half their water of crystallization, and at a higher temperature the whole. The mass fuses into a hard transparent glass, but will not sublime except at a white heat. Unless protected from the air it absorbs water and loses transparency. Deprived of water, its specific gravity is 1.8; that of the hydrate is 1.48. Boiling water dissolves one third of its weight of the crystals; cold water only about one thirtieth. They are soluble in alcohol, and when this is ignited the acid gives to the flame a beautiful green color. This is employed as a characteristic test of its presence. The acid properties of this substance at ordinary temperatures are very feeble. It scarcely reddens vegetable blues, and turmeric paper is rendered brown by it as by an alkali. It is expelled from its combinations by stronger acids almost as readily as carbonic acid is. But at high temperatures, as when exposed to a red heat in a crucible, boric acid mixed with sulphate of soda expels the sulphuric acid, and combines with the soda; when cold, the process may be reversed.—In boiling the aqueous solution, the acid is taken up by the steam; much more, however, is this the case with the alcoholic solution. It is to this property we owe the supplies of boric acid, which are furnished from the interior of the earth by jets of steam that issue through fissures, and come up more or less laden with this material, as well as other substances, as sulphur, sal ammoniac, clay, and gypsum. The acid is deposited in the soil in the form of solid efflorescences, or is collected in pools of water, through which the jets are made to pass. In South America it is collected upon the surface of the ground. At an island of the Lipari group, called Vulcano, 12 m. N. of Sicily, it rises in vapor at the bottom of the crater of an extinct volcano, 700 ft. below its summit. The vapor condenses here upon the bottom and sides, like frost after a heavy dew; but it goes on accumulating, till it resembles more a bed of clean snow; beneath it is found a layer of red-hot sal ammoniac, through which come up sulphurous vapors. The boric acid is gathered up as it collects, and with the sulphur and sal am-

moniac is a source of no little profit to the proprietors of the volcano. It is also found at Sasso in S. Italy, and has hence been called sassoline. But the great supplies of it are obtained from the volcanic districts of Tuscany. Here, over an area of some 30 m. of wild mountain land, issue through beds of calcareous rocks, black marl, and sand, numerous jets of steam, which rise in white clouds among the hills, and spread around offensive sulphurous smells and vapors, that drench those passing by the spot. The ground itself is hot and undermined. It shakes beneath the feet, and is sometimes so treacherous as to let man or beast walking upon it fall through into its heated recesses. Its surface is covered with incrustations of sulphur and saline substances. The waters beneath are heard boiling with strange noises, and are seen to break out upon the surface. Of old it was regarded as the entrance to hell. The name Monte Cerboli (*mons Cerberi*) is still retained by a neighboring volcano, and contains the principal lagoon or pool from which the acid is obtained. The great value of these natural exhalations, or *soffioni*, as they are called, was discovered in 1818, and made available by the skill and ingenuity of Count Larderel. Wherever up the slopes of the hills the ground is observed to be hotter than usual, and sulphurous vapors are seen to rise from it, and the surface is felt to tremble, a pit is dug, from which soon issues a column of steam. A temporary wooden chimney is put up for this to pass through, so that the workmen may continue the excavation, and construct a basin with stone wall lining, to contain the water intended to receive and collect the acid brought up by the steam. The water is introduced from some supply at the surface, and the chimney is then removed. The heat soon causes the water to reach nearly the boiling point. It penetrates into the fissure, and is rejected by the steam, bringing up with it a portion of boric acid. As it is found that the quantity which the water is capable of absorbing is very small, fresh supplies are introduced every day; and the pits are so arranged down the slope of the hill that the water entering at the top passes from an upper basin into a lower one, and so on, till at the foot it is received into large evaporating pans. The basins or "lagoons" are of rough shapes, rudely constructed, from 5 to 8 ft. deep, and from 13 to 60 ft. in diameter; they continue to receive the vapors for years, but the jets are liable at any time to cease and break out in a new place. The pans are very numerous, and present a great evaporating surface. They are heated by the vapors of some of the *soffioni*, which are conveyed under them in flues. After the liquor has passed through a series of the pans and been greatly concentrated, it is baled out and drained through baskets, and the precipitated salt is taken to the drying rooms. These are of brick and warmed in the same manner as the pans are heated. Thus the operations are

carried on with no expense of fuel, and boric acid is obtained to the amount of 5,000,000 Tuscan pounds or more per annum. Since 1854 artificial soffioni have been produced by boring, and the yield from this source is very large. The product is of late years more impure than formerly, the foreign matters having increased from 8 per cent. to 25 per cent., which appears to have excited some apprehension lest the supply may give out. An analysis of the crude acid made by Vohl in 1866 is interesting, as showing the great variety of the associated substances. It is as follows:

Boric acid crystallized.....	80.000
Hygroscopic water.....	4.500
Sulphuric acid.....	9.610
Silicic acid.....	0.810
Sand.....	0.800
Oxide of iron.....	0.120
Oxide of manganese.....	0.001
Alumina.....	0.570
Lime.....	0.010
Magnesia.....	0.600
Potash.....	0.180
Ammonia.....	2.980
Soda.....	0.002
Chloride of sodium.....	0.100
Organic matter and loss.....	0.217

100.000

Our knowledge of the Tuscan locality, and the process as there conducted, is derived from the treatise of Payen, who describes it in detail. Sir John Bowring and Durval have also furnished interesting data concerning it. Boric acid is of value principally for the preparation from it of borax. It is used in manufacturing a paste for artificial gems, and in making enamel. Its price in Tuscany is about 10 cents a pound.

BORIE, Pierre Rose Ursule Dumoulin, a French missionary, born at Beynat, Feb. 20, 1808, put to death in Tonquin, Nov. 24, 1838. After completing his studies for the priesthood, he sailed for Tonquin, Dec. 1, 1831, arriving just at the commencement of a bloody persecution of the Christian converts. He very soon learned to speak the language and accommodate himself to the habits and temper of the Tonquinese, and labored with great zeal and success for six years. In 1838 he was apprehended, severely beaten, and imprisoned, and after four months condemned to be beheaded. He bore his tortures with fortitude, and such was the veneration of the people for his character that no one was willing to deal the fatal blow. The soldier selected for that purpose intoxicated himself, and performed the task so awkwardly that seven strokes were necessary for its completion. After his death the heathens burned gold paper over his grave and honored him as a divinity.

BORING, a name common to two distinct mechanical operations, which bear different appellations in most languages. The one consists in turning the inside surface of cylinders to make them true, the other in cutting holes through solid matter. Cylinders of a diameter smaller than four feet are bored on a lathe; the cylinder is fastened to the slide-rest, and the tool is keyed on a mandrel or boring bar held between the centres of the lathe; the cylinder

moves lengthwise, and the tool revolves so that the cut is helical. Large cylinders of the thickness usual for steam engines are bored on a vertical machine, as their weight is sufficient to deflect them when resting on the side. This important tool is of modern invention, and is found only in those large establishments where huge steam engines are built. A boring machine is generally placed in a corner of the shop formed by two solid walls. It consists mainly of a vertical shaft placed below the floors, supporting a vertical boring bar which carries a horizontal cutter wheel, and of a strongly ribbed bed plate on which are four movable standards or supports, with clamps to hold the cylinder in a vertical position. The lower end of the shaft rests in a socket on strong foundations; the upper end is keyed loosely to the boring bar, and supports it. The boring bar is guided by two adjustable boxes, the lower one forming a part of the bed plate, the upper one part of an iron beam strongly bolted and braced to the walls. The shaft and boring bar are made to revolve by a train of wheels placed under the floor. The cutter wheel, on which are bolted several tool-carriers, descends slowly along the boring bar. To operate with this machine, the boring bar is at first withdrawn, to make room for the cylinder, which is placed on the standards, and then the bar is put back in its place inside the cylinder. This last is then so adjusted as to have the same axis with the boring bar, and is firmly clamped. Cutting chisels are set on the tool-carriers; these are adjusted for the depth of cut desired, and the ma-

FIG. 1.—Boring Machine.

chine is put in motion. After the cutter wheel has come down the whole length of the cylinder, it is raised by means of a revolving crane

for another cut. Boring machines were made to avoid the bulging of the sides of cylinders when placed horizontally, as this was the main impediment to good boring; they also avoid the deflection of the boring bar. They require much less power than lathes to do the same work, and have several other minor advantages. Messrs. Nasmyth, Gaskell and company constructed the boring mill represented in fig. 1 for the purpose of boring the large cylinders, 10 ft. in diameter, for the Great Western steamship navigation company's vessel the *Mammoth*, at their works at Bristol. The motion is communicated by the driving pulley *c* to a bevel pinion working the bevel wheel *d*. The shaft on which this wheel is fixed has on its opposite end a worm for communicating motion to the upright shaft *f* and boring bar *a*. This boring bar has vertical grooves *a'*, in which the cutter head *b* is movable, sliding up and down according to the progress of the work; *k* is a tool-carrier, fixed to the cutter head, by which the boring is effected. The foundation plate *h* forms a bearing for the upright shaft, the lower end of which rests in the step *g*, while the cylinder *l* is secured by the clamps *jj* to the supports *ii*, which are fixed to the foundation plate. Two strong pieces of masonry, *m'*, support the entablature *m*, for carrying the self-acting apparatus for raising and lowering the cutter head *b*. The entablature is secured to the masonry by strong holding down bolts. This self-acting apparatus consists of a rack, *n*, worked by a pinion, the motion being transmitted by trunnion wheels through two spur wheels and pinions, *oo*. The whole of this upper machinery revolves with the boring bar, with the exception of the ring *p*, upon which the trunnion wheels rest and revolve. The motion thus produced is communicated to the rack, which is either raised or lowered according to the direction in which the boring bar revolves. Smaller hollow cylinders are bored in a similar manner, except that they are usually placed in a horizontal position. The cutter head may be made to revolve in the cylinder, or the cylinder may revolve about the cutter head. The barrels of muskets and other small firearms, being forged hollow, are bored upon a similar principle. The barrel is screwed on a carriage which moves in iron grooves, and is propelled toward the boring bar by a rope which passes over pulleys and has a weight hanging from the end. (For the boring of cannon and rifle guns, see *CANNON*, and *RIFLE*.)—In the boring of solid substances various questions require to be taken into consideration. If the tools had only to cut away a portion of matter, as is done in cutting, planing, and turning, the directions given for cutting tools as to the angles of the faces of the edge with the work, the velocity, and the lubricating liquid proper for the substance to be cut, would have to be strictly applied. Such is not the case, however; a drill has not only to turn off the bottom of the hole,

but also to pare its sides, to guide itself in a straight line, and, for wood and some other substances, to eject the shavings. Moreover, the velocity is unavoidably different at all points from the centre to the circumference. In consequence, the rules given for cutting tools are observed in boring tools only as far as they accord with other important requisites; but they must never be lost sight of. Drills are made, in general, to bore straight holes, by providing them with a centre point or pin projecting beyond the cutting edge just in the centre of the hole, or by tapering the cutting edges to a point. They are made to bore clean holes, by providing them with a shearing point on the side, that cuts like the point of a knife;

FIG. 2.

FIG. 3.

FIG. 4.

or by prolonging the cutting edge along the side; or, for metal, by making a reamer with the stem of the drill (figs. 2, 3, and 4). Boring tools are made to eject the material cut away, by shaping the stem in the form of a screw, or by making it hollow. The various tools used for boring wood are as follows: The bradawl (fig. 5) is a cylindrical wire, with a chisel edge; it packs the material around the hole. The awl

FIG. 5. FIG. 6. FIG. 7. FIG. 8. FIG. 9. FIG. 10.

(fig. 6) is a square bar tapering to a point. A great number of tools are fluted, that is, have the shape of the half of a tube. Such are the gouge bit (fig. 7), the spoon bit (fig. 8) and its varieties, the table bit and the cooper's dowel bit, and the nose bit or auger bit (fig. 9). The gimlet (fig. 10) is fluted, but terminates in a screw, which drives it into the wood. The centre bit (fig. 11), an instrument of English invention, consists of a centre point, a shearing point, and a broad inclined cutter. Its varia-

tions are called plug centre bit, wine cooper's centre bit, and expanding centre bit. The tools in the form of a screw are the single-lip auger (fig. 12), made of a half-round bar wound

FIG. 11. FIG. 12. FIG. 13. FIG. 14. FIG. 15. FIG. 16.

spirally around a cylinder; the twisted gimlet, (fig. 18), made of a conical shaft, around which is cut a half-round spiral groove; the screw auger (figs. 14 and 15), formed of a flat band of steel twisted when red hot; the American auger (fig. 16), made of a solid shaft, around which is a thin helical fin. The last much resembles a wood screw; the cutting edge is removable, and resembles that of a centre bit. All these twisted tools are of American invention, and were scarcely known in Europe 30 years ago. Another American tool is an auger for producing square holes or cutting mortices: it consists of a screw auger working in a tube, round inside and square outside; the four corners at the lower end of the tube are sharpened from inside, and proceed forward a short distance behind the cutting edge of the auger, cutting through the wood as they advance, and making the round hole square. Several

FIG. 17.—Drilling Machine.

of these tools working side by side will cut an oblong hole. Boring tools for wood are worked by means either of a lathe, a carpenter's brace, a transverse handle, or a drilling machine. (See fig. 17.)—Boring tools for metal are called

of about 60° sharpness. Another double-cutting drill, called the Swiss drill, is made of a wire filed on one side to the diameter, the end of the remaining half being ground in the shape of a half cone. The common single-cutting drill, fig. 8, is forged flat and cut pointed, so as to show at the end two small faces meeting at an angle of 90°, and forming a point projecting in the centre line of the tool. These two faces are ground so as to form angles of 60° with the flat sides of the tool; the one face forming this angle with one side, the second face with the other. This drill is in universal use, the angles specified being slightly modified according to the nature of the metal to be bored. It is very difficult to drill a hole in the exact place where it is designed to be, and the error is proportional to the size of the drill. For this reason, when exactness is required for a large hole, a small hole is drilled first, and this is enlarged by means of a pin drill. The shape of a pin drill is exactly represented by placing two carpenter's chisels side by side, the one presenting its face, the other its back, to the person holding them, and by letting the end of a wire project between them a little below the edges. In using the instrument, the centre pin must enter and fit the small hole previously bored, which acts as a guide. If the portion of the cutting edges nearest the centre pin is cut away, the tool will cut a circular groove; such is the form adopted for cutting holes in the tube plates which receive the tubes in locomotives. These drills are worked in various kinds of braces, in the lathe or in the drilling machine. After they are drilled, the holes of all carefully made machines, which are not tapped, are perfected by reaming. A large proportion of holes drilled are intended for screws, and are consequently tapped. Taps, master-taps, stocks, dies, and reamers are costly tools; hence it is the interest of machinists to devise and adopt a uniform system in drilling and making screws, so that a machine may be repaired in another shop than that of the maker, without the necessity of making a new set of tools for each particular case. Hard steel and glass are bored with the end of a rotating brass rod fed with oil and emery. Glass offers also this remarkable and little known peculiarity, that it is drilled through as easily as hard woods with a common metal drill, provided the drill is kept all the time moistened with turpentine.—In boring rocks for blasting, the common hand drill and the jumper are more used than any other tools. (See BLASTING.) The situation of the place in which the holes are to be drilled is often very difficult of access with a machine, so that the time and expense employed in adjusting the apparatus would make it preferable to employ manual labor. When, however, large holes are desirable for the displacing of masses of rock, machines worked by compressed air furnished by steam power, when they can be placed in working position, are to be pre-

ferred; and, in fact, in all modern blasting on a large scale, the greatest amount of displacement of rock is effected by blasts which are made in the holes drilled by machines.

Among the most noted of the rock drills, having been the longest in use, and the principal one employed in excavating the Hoosac tunnel, is the Burleigh drill, a general outline of which and its mode of working are represented under **BLASTING**. It is what is called a percussion drill, that is, a drill whose bit is driven by blows against the rock, and is usually propelled, as are

the other drills to be noticed, by compressed air, which is furnished by a double-cylinder pump, called the air compressor, fig. 18. The backward and forward motion of the piston rod to which the drill is attached is produced in the same manner as in an ordinary high-pressure steam engine. The Ingersoll drill is especially effective in excavating open cuts. In the engraving, fig. 19, *c* is the cylinder, *s* the steam or compressed air chest, *h* the pipe which supplies the compressed air, and *p* the screw for moving the drill forward, which may be done by the hand or by the rod *g*, which is turned by an automatic ratchet movement. Various attachments are used for the purpose of rotating percussion drills as well as for feeding them, a general idea of which may be gathered from the following description of a

drill (fig. 20) invented by Prof. De Volson Wood of the Stevens institute at Hoboken, N. J. The piston, piston rod, drill holder, ratchet for rotation, and enlargement for regulating the feed, constitute a single piece of cast steel. The small valve *a* is operated by the reciprocating movement of the plug *b*. Steam is admitted behind the plug *b* so as to keep it constantly pressed against the plug *c*, which rests upon the conical surface *d*. During the backward movement of the piston the small valve is forced upward by the conical surface, and during the forward movement it is moved downward by the pressure of the steam behind

Fig. 20.—Wood's Drill.

the plug *b*. This small valve admits the motor so as to reciprocate the piston *e*, and this piston operates the main valve *f*. The length of the stroke is adjusted by simply turning the piece *g*. By this arrangement the valve is operated without shock, and hence will not break, and when properly set the main valve will not be opened until the blow is struck. The drill is seized and held automatically by the conical wedges *i*, and is rotated by the sloping click *k*, which rotates about its back edge, coming in contact with sloping teeth *l* on the enlargement of the piston rod. The click *m* prevents it from feeding forward, and the click *n* in a similar manner prevents it from feeding back. The thread on the screw *o* is made very steep, so that when the piston advances so far as to drive *m* out of bearing, the pressure of the motor on the forward head, *p*, during the backward stroke of the piston, forces the cylinder forward, which will cause the screw *o* to turn, thus securing an advance feed. A false head, *r*, to prevent the piston from striking the rear head, has the motor admitted and retained behind it by a puppet valve.—The diamond drill, owned by the American diamond drill company, the bit of which is the invention of Rodolphe Leschot of Paris, is a rotary machine, and of course differs widely in construction from those just described. There are several patterns and sizes; that represented in fig. 21 is a small tunnelling drill. It is so adjusted that it can be placed in any required position, moving as if on a universal joint. The bits, which are screwed on the end of the drill rod, are armed with black diamonds as represented in figs. 22 and 23. It will be observed that the diamonds are so arranged as to cut the hole larger than the diameter of the bit or the drill. Both the drill rod and the bit are hollow to admit water, which

Fig. 19.—Ingersoll Drill.

is forced down to the bottom of the hole while the machine is at work. This drill is now (February, 1873) in use by the United States

FIG. 21.—Diamond Drill.

government in deepening the channel of the James river below Richmond, Va. It is much used in prospecting for coal and other mine-

FIG. 22.

FIG. 23.

erals, and for boring artesian wells, and is especially adapted to these purposes. At the Lackawanna coal and iron company's mines the total boring in 67 days in the year 1872 was 6,357 ft.,

with an average number of $2\frac{1}{2}$ drills, the average of each drill per day being 34 ft. The average cost of the diamonds was $18\frac{1}{4}$ cents per foot.

BORISOGLEBSK, a town of Russia, in the government and 90 m. S. by E. of Tambov, on the Vorona, a tributary of the Don; pop. in 1867, 12,254. It has an important fair, manufactures of various kinds, and a large establishment for the melting of tallow.

BORISOV, a town of Russia, on the Beresina, in the government and 44 m. N. E. of Minsk; pop. in 1867, 5,233. Near the adjacent village of Studienka the Beresina was crossed by the French army, Nov. 26 and 27, 1812. (See *Beresina*.)

BÖRJESSON, Johan, a Swedish dramatist, born at Tanum, March 22, 1790, died in Upsal, May

5, 1866. He was minister of the church of Weekholm near Enköping from 1828 till his death. His first and best drama, *Erik XIV.* (1846; German translation, 1855), was succeeded by many tragedies. In 1861 he became one of the 18 members of the Swedish academy.

BORLACE, Edmund, an English historian, a physician by profession, died at Chester about 1682. His father, Sir John Borlace, was one of the lords justices of Ireland, and he was educated at Dublin and Leyden. He practised his profession at Chester, and wrote among other works "The Reduction of Ireland to the Crown of England, with the Governors since the Conquest by Henry II. in 1172" (London, 1675), and "The History of the execrable Irish Rebellion, traced from many preceding acts to the grand Eruption, Oct. 23, 1641, and thence pursued to the Act of Settlement, 1661" (London, 1680).

BORN, Bertrand de, viscount of Hautefort, a French troubadour and warrior, born in the castle of Born, Périgord, in the middle of the 12th century, died about 1209. He belonged to an ancient family which traced its origin to the duke of Aquitaine, and early contended with his brother for the supremacy over the vast family domain, which contained 1,000 serfs. Richard Cœur de Lion took the dispossessed brother's part in revenge for Bertrand's satirical lays, upon which the latter espoused the cause of Henry II. and took a prominent and mischievous part in these family broils and wars, especially as Aquitaine was threatened both by France and England. After the death of Richard, whom he as well as other princes had instigated to go to the Holy Land without himself contributing anything to the crusades excepting spirited songs, he lived in retirement, as was believed in a monastery, and the fief of Hautefort was transferred in 1210 by his son Bertrand (who also wrote several songs) to the king of France. Eleanor of Aquitaine, wife of Henry II., was said to have been one of his patronesses; he was also in love with Helena, sister of Richard, though he celebrated Maenz, daughter of the viscount of Turenne, and wife of Talleyrand of Périgord, as the special object of his adoration. Dante places him in his inferno for leading the youthful king to quarrel with his father; and Thierry as well as Sismondi refers to the influence of his lyrics and of his sword and counsels in stimulating and embittering the spirit of contention of his day.—See Laurens, *Le Tyrtée du Moyen Age, ou histoire de Bertrand de Born, vicomte d'Hautefort* (Paris, 1863).

BORNA, a town of Germany, in the kingdom of Saxony, on the Wylra, 16 m. S. S. E. of Leipzig; pop. in 1871, 5,751. It has an old Gothic church, and the ruins of an ancient castle, which was destroyed by the Hussites in 1430. The town has a considerable industry.

BÖRNE, Ludwig, a German author, of Jewish origin, born at Frankfort-on-the-Main, May 18, 1786, died in Paris, Feb. 13, 1837. His

father, Jakob Baruch, was a banker, and his grandfather was employed on a diplomatic mission to Vienna. He studied medicine, philosophy, and political science at Berlin, Halle, Heidelberg, and Giessen, and then entered the public service at Frankfort. When that city was restored to the condition of a free town he turned his attention to literature, and established two journals, the *Staats-Ristretto* and the *Zeitschwingen*, at Offenbach, near Frankfort. These were suppressed on account of their boldness in dealing with public affairs, and the editor was arraigned for circulating seditious pamphlets. He was acquitted, and in 1818, having in the mean time become a convert to Christianity and changed his name, he established a paper called *Die Wage*, which became famous by theatrical criticisms. He was a severe and caustic critic of the existing order of things, and lived much in isolation at Frankfort, Hamburg, and Paris. After the revolution of 1830 he established *La Balance* in Paris, with a view to creating a closer intellectual and social union between France and Germany. His *Denkrede auf Jean Paul*, remarkable for great elevation of thought, and his *Menzel der Franzosenfresser*, a fierce satire, are his best productions. Most of his writings are included in his *Gesammelte Schriften* (17 vols., 1829-'47) and *Nachgelassene Schriften* (6 vols., Mannheim, 1847-'50).

BORNEO, an island of the East Indian or Malay archipelago, situated directly under the equator, which divides it into two nearly equal parts. It is the largest island in the world with the exception of Australia, and possibly of Papua or New Guinea. Its native name is Pulokalamantin. It extends from about the 7th parallel of N. latitude southward a little further than lat. 4° S., and from its most western point, near the 109th meridian of E. longitude, eastward to Kaniungan point in lon. 119° 20' E.; its greatest length, which is from N. N. E. to S. S. W., is about 850 m., and its greatest width about 680 m. It is bounded N. and W. by the China sea, E. by the Sooloo sea, the Celebes sea, and Macassar strait, which separates it from the island of Celebes, and S. by the Java sea. Its estimated area is from 284,000 to 300,000 sq. m. The northern portion of Borneo is a peninsula with an average width of 120 m., trending from lat. 2° 30' upward of 300 m. in a northeasterly direction. The population is variously estimated at from 2,500,000 to 3,000,000.—Borneo has about 2,000 m. of sea-coast, in which there are comparatively few important bays or indentations, and no great inlets, but many rivers and small creeks. Along the entire S. coast the shores are low and generally marshy; the features of the E. coast up to Kaniungan Point, and of the W. coast up to Cape Datu, nearly opposite, are similar. The shores of the peninsula, however, are bolder, being rocky and lined with islets perilous to navigation. They enclose several bays of considerable extent, of which the more important are:

Maludu bay, which is sheltered by Cape Sampanmanjo, the N. extremity of the island, and was formerly a favorite resort of pirates; and Labok bay and Gyong bay, on the E. side of the peninsula, with the Unsang promontory between them, where edible birds' nests are gathered in large quantities for the Chinese market. Off the W. coast of the peninsula, in lat. 5° 22' N., lies the little island of Labuan, the seat of a small but important British colony.—An inland range extending from S. W. to N. E., with an average elevation of from 3,000 to 4,000 ft., forms the watershed of the great northern peninsula. At its extremities it curves outward toward the sea, and terminates in Cape Datu and Cape Sampanmanjo respectively. Its name changes, in proceeding northward, from the Krimbang mountains, which form the inland boundary of the territory of Sarawak, in the northwest, to the Batang-Lupar, and finally to the Madi mountains, whence the region comprised in the kingdom of Borneo proper slopes down to the Chinese sea. The chain attains its greatest height in Mt. Kina-Balu, the loftiest peak yet discovered in Borneo, 13,698 ft. above the level of the sea. It is near the northernmost end of the island, and as seen from the coast presents the appearance of a vast truncated cone. The summit, which has been thrice reached by Europeans, consists of syenitic granite, and is about 2 m. in length. Lofty detached mountains are visible to the eastward, apparently at least 7,000 ft. high, and a long chain stretches away in a S. S. W. direction. The main peninsular range is prolonged beyond Mt. Kina-Balu, and terminates in Cape Sampanmanjo. Apparently unconnected with it and much nearer the sea is Mt. Malu, in about lat. 4° N. with an altitude of 8,000 ft. In the central portion of the island, the Madi mountains form a group whence radiate several ranges toward different parts of the coast. Of these, one extends from Mt. Beringin, in about lat. 2° 30' N., easterly to Kaniungan point, and a second, the high Anga-Anga mountains, southward to Cape Salatan, the southern extremity of Borneo; there is also a third range which separates from the Anga-Anga mountains not far from their junction with the central group, and runs westward, as the Kaminting and Pembaringan mountains, until it is broken up into detached masses as it approaches the 110th meridian.—The navigable rivers of Borneo are numerous. Many of them are deep enough to admit of navigation by larger craft than can pass the bars which in most instances obstruct their entrance. It is said that on the N. W. coast, between Cape Datu and Cape Sampanmanjo, 23 rivers enter the sea, each navigable for vessels drawing 12 ft. of water to a distance of 100 m. above its mouth. Among these may be mentioned the Sarawak, which has two outlets, its western mouth being situated in about lat. 1° 20' N., lon. 116° 30' E. The anchorage near the town of Sarawak is 17 m. from the sea. The Batang-

Lupar is another large stream which drains the Sarawak territory. Its embouchure, which is 4 m. wide, is near lat. $1^{\circ} 25' N.$ and lon. $111^{\circ} E.$ Flowing seaward from within the confines of the same state are the rivers Rejang and Bintulu. Further N. E., in Borneo proper, is the Limbang, Kadayan, or Brunai, with the capital of the kingdom, a town of 25,000 inhabitants, known as Brunai or Borneo, on its left bank. The island of Labuan lies just without the bay or gulf into which it flows. Maludu bay, which indents the most northern portion of Borneo, receives a stream said to flow out of Lake Kina-Balu, a sheet of water near the mountain of that name, the existence of which is positively asserted by the natives, but which has not been seen by any European. The principal rivers which enter the Celebes sea are the Bulongan, which rises in the Anga-Anga range and flows eastward through the

Sooloo dominions, reaching the coast near lat. $8^{\circ} 10' N.$, lon. $117^{\circ} 30' E.$, and the Pantai, which has its sources in the same mountain group, and pursues a parallel course down to its mouth, which is about $2^{\circ} N.$ of the equator. The only river of any considerable length which flows into Macassar strait is the Koti, a stream which waters the region bearing its own name, and which is fed by numerous affluents. Its general course is S. E., and its delta occupies the coast region from 10 to 50 m. S. of the equator. The Banjar is the chief of the rivers having their outlet in the Java sea on the S. coast. It takes its rise near the middle of the island, and is a tortuous stream, flowing southward along or near the 115th parallel, and eventually separating into two branches, one of which is known as the Little Dayak river, the other and principal arm being the avenue to the important Dutch settlement of Banjar-

Mount Kina-Balu.

massin, which stands on its left bank. Other rivers on this coast are the Great Dayak, the Mendawi, the Sampit, the Pembuan, the Kotta-Waringen, and the Jelli. The great river of western Borneo is the Simpang, which drains the extensive region comprised between the peninsular range on the north and the western offshoot of the Anga-Anga mountains, portions of which are known as the Kaminting and Pembrangan ranges. Its general course is in a westerly direction almost under the equator, from its source in lon. $114^{\circ} 10' E.$ to lon. $109^{\circ} 20' E.$, where the Chinese town of Pontianak is situated on one of its main outlets just above the mouth. In 1823 a Dutch expedition in search of gold and diamond fields explored this river for a distance of 300 m. inland. The Sambas territory, further N., is watered by the Sambas river.—The greater

part of Borneo belongs to recent geological formations. The shallow seas which separate the island from Asia, and the resemblance between Bornean and Asiatic natural productions, indicate that at no very distant epoch the continent extended further S. W. than at present, and included Borneo as well as Sumatra and Java. No trace of recent volcanic action has been observed in Borneo, though the island is almost surrounded by one of the most important belts of volcanoes in the world, near which earthquakes (also wholly unknown in Borneo) are of weekly or monthly occurrence. The island is notably rich in mineral productions, among which are diamonds, gold, antimony, coal, tin, iron, copper, and lead. Diamonds occur in the sand and gravel of the river beds, at depths from 6 to 15 ft. below the surface, and in strata occasionally several feet in thick-

ness, whence they are obtained by Malays, who sink shafts in the rivers for this purpose. The largest diamond ever found in Borneo weighs 367 carats. Diamond washing is carried on to some extent in the Sarawak river, which yields small stones of brilliant water; but the largest product is in the Landak district, in the Dutch dominions, 40 m. N. of the equator. Gold is found in Sarawak as well as the districts under the government of the Netherlands, but only as small grains in alluvial deposits. The anti-mony exported from Borneo through Sarawak constitutes the chief supply of Great Britain. The principal mines are at Bidi, near which some traces of silver have been discovered. Coal of good quality occurs abundantly at the British island of Labuan, and in the Dutch Banjermassin district. It has also been found in Sarawak, and on the Koti river. Excellent iron ore abounds in the south, and is also met with in the northwest. The natives manufacture it into the best cutting blades to be found in the archipelago. A copper mine is worked by the Dutch in the Sambas country. Small quantities of platinum have been obtained in some localities, but this metal has never been profitably extracted.—The climate of Borneo is remarkably salubrious for an equatorial island. The low regions of coast land and extensive forest are hot and moist, with an average temperature throughout the year of about 70° F. between 6 and 7 o'clock A. M., and an annual rainfall in some places estimated at 300 inches. The wet season on the western side of the island is synchronous with the dry season on the eastern shores, from April to September, at the time of the S. E. monsoon; with the beginning of the N. E. monsoon in September the wet season sets in along Macassar strait and the shores of the Java sea, lasting till April. In the higher districts the climate is temperate and healthy.—The vegetation of Borneo is rich, luxuriant, and varied. The island is essentially a forest country, and abounds in gigantic trees. Brilliant flowers are scarce. The most striking vegetable productions are the wonderful pitcher plants of the botanical genus *nepenthes*, which here attain their highest development in form and color. They grow on the mountains, and vary greatly in size and appearance. The pitcher of one species will hold two quarts of water. They are usually green, with red, brown, and purple markings and linings. There are probably 100 species of ferns on the island, and the orchids are well represented. The finest fruit is furnished by the abundant durian tree, which resembles the elm in general appearance. A spiny oval mass contains the fruit in the form of a cream-colored pulp. Other fruit trees are the mangosteen, lansat, rambutan, jack, jambon, and blimbing. The bamboo is put to many important uses in the native economy. Among the valuable products of the Bornean forests are bananas, betel nuts, breadfruit, camphor, cocoanuts, ebony,* gutta

percha, rattan, and sandal wood. The soil is generally very fertile, and yields rice, sago, manioc, cotton, sugar, cloves, nutmegs, poppies, and ginger. Melons and gourds are produced in large quantities, and in addition to the more distinctive fruits already mentioned are found the orange, lemon, mango, tamarind, and pomegranate.—The orang-outang or mias (*simia satyrus*) occupies the most prominent place in the fauna of Borneo, which, with the exception of Sumatra, where it is rarely met with, is believed to be its exclusive habitat. These creatures frequent the dense virgin forests of the low country, and are not to be found in the dry and elevated districts. The quadrumana are further represented by the long-nosed monkey and at least ten other species. There are four species of lemur-like animals. The carnivora are sparingly represented, a species of arboreal panther (*felis macrocelis*) being the most noteworthy animal of this order. The elephant is occasionally encountered in the north, and is believed to be identical with that of India. The only other large quadrupeds are deer and wild cattle (*bos Sondaiicus*). Wild hogs roam through the forests in vast numbers. There are numerous bats and many characteristic species of squirrels. A curious representative of the insectivora is the small feather-tailed *ptilocercus Lowii*. Of birds there are parrots, woodpeckers, trogons, pheasants, partridges, hornbills, cuckoos, bee-eaters, and gapers. Of insects there are honey bees, 2,000 species of beetles, and no fewer than 29 species of *papilionides* or gorgeous swallow-tailed butterflies. Crocodiles, tortoises, and pythons and other serpents are met with. The adjacent seas and the rivers abound in fish, which form a considerable article of consumption and commerce.—The principal territorial divisions of Borneo are as follows: 1, Sarawak, an independent state under an English rajah, extending about 300 m. along the N. W. coast, with a population of 300,000; 2, Borneo proper, one of the few Malay kingdoms which remain in the archipelago, embracing the N. W. coast of the peninsula to Maludu bay, population unknown; 3, the Dutch territories on the S., E., and W. coasts, comprising Sanbas, Banjermassin, and Pontianak, with an aggregate area of 201,541 sq. m., and a total population in 1869 of 1,189,308. These dependencies are included under the administration of the Dutch governor of Java.—The inhabitants comprise the aboriginal Dyaks and the immigrant Malays, Javanese, Chinese, and Bughis or natives of Celebes. The Dyaks are closely allied to the Malay race, but are more simple and honest, and morally superior in almost every respect. Their average stature somewhat exceeds that of the Malays; their hair is straight, coarse, and black, and they are well proportioned without any tendency to obesity. Agriculture is their principal means of subsistence. They are distinguished by many excellent traits of character, and when kindly

treated are docile, industrious, and faithful. They formerly gained great notoriety as daring pirates and head-hunters, seeking to decapitate others under the belief that every person beheaded would become the slave of the hunter in the next world. The greater portion of them have substantial dwellings, and cultivate rice, the banana, sugar cane, and some cotton and tobacco for their own consumption. They are skilled artificers in iron, and understand spinning and weaving, but have no written language. Dogs and fowls are their only domesticated animals. The distinction between Land Dyaks and Sea Dyaks is founded not upon the localities which they inhabit, but upon the favorite pursuits of the respective tribes, which lead some to cultivate the soil and others to a life on the water. Chinese settlers are found in all parts of the island, and engage in trade, local manufactures, and mining. The most active traders, however, are the Bughis, who are superior sailors, and visit every section of the coast in their light vessels.—Antimony, spices, camphor, gold, and diamonds are the principal articles of export from Borneo to Europe. The British and Dutch carry on a considerable commerce with the island, the former mainly through the free port of Singapore.—Borneo appears to have been visited by the Portuguese very early in the 16th century. Nearly 200 years later, in 1690, they acquired a temporary foothold in Banjarmassin, which they were soon compelled to relinquish. The Dutch subsequently established themselves on the same coasts, and in 1787 gained supremacy over Banjarmassin by a treaty with its sultan. The sway thus inaugurated has been maintained almost continually up to the present time. In 1823 they settled Pontianak. Great Britain made unsuccessful attempts to establish commercial factories in Borneo in the years 1702 and 1774; but owing to the foundation of the state of Sarawak under an English ruler, and the acquisition of Labuan as a colony, British influence is now paramount in the N. W. part of the island. (See SARAWAK.)

BORNHEIM, a village of Germany, in the province of Hesse-Nassau, close by Frankfort-on-the-Main, for the inhabitants of which it forms a favorite resort for pleasure; pop. in 1871, 6,396. On the *Bornheimer Heide*, near the town, on Sept. 18, 1848, Prince Liehnowski and Von Auerswald, two prominent conservative members of the German parliament, were assassinated by a mob.

BORNHOLM, an island in the Baltic, belonging to Denmark, 23 m. S. E. of Sandhammar point, Sweden, and 90 m. E. of Seeland; area, 225 sq. m.; pop. in 1870, 31,894. It is about 23 m. long by 18 wide. The coast is high and rocky, skirted in many places by dangerous reefs, and there are no good harbors for large vessels. A range of mountains with dry and sterile slopes runs through the interior; but the lower land is generally fertile. The island produces coal, marble, building stone, sheep,

and cattle; and earthenware is made. The capital is Rønne, at the S. W. angle of the island.

BORNOO, or *Bornu* (called by the natives *Kanowry*), a country of central Africa, between lat. 9° and 14° N., and lon. 8° and 15° E., bounded N. by the Great Desert, E. by Lake Tchad and Baghirmi, S. by Mandara, and W. by Housa. The country is level and wholly destitute of minerals. The chief rivers are the Komadugu and the Shary, which with numerous small streams flow into Lake Tchad. During the wet season large tracts are overflowed by the waters of the lake and rivers. The fertility caused by this inundation produces only a rank growth of grass from 10 to 12 ft. in height, and almost impenetrable thickets of underwood. Nearly all the wild animals, reptiles, birds, and insects common to central Africa infest this region in great abundance, and are driven to

Body Guard of the Sultan of Bornoo.

the inhabited districts during the inundations. Domestic animals are also plentiful. The climate of Bornoo, especially from March to the end of June, is excessively hot. During the rainy season, from May to October, fevers are prevalent. The soil is fertile, and, though but imperfectly cultivated, produces large crops. A species of millet forms the staple food of the people; rice and grain of an inferior kind are raised in small quantity. There are no fruits. The mass of the inhabitants, called *Bornooes* or *Kanowry*, are genuine negroes, peaceable and lazy, and wholly subject to the Arabs, who form the dominant race. The Arabs are described as arrogant, deceitful, and dishonest, and carry on the trade of the country, dealing chiefly in slaves. They are bigoted Mohammedans, but fetishism is still common among the negroes. The government of Bornoo is nominally vested in a sultan, but all the power

really resides in an Arab sheik. The sultan is surrounded by a body guard of nobles and chiefs, clad in a grotesque and unwieldy garb. The military force of this monarch amounts to about 30,000, mostly cavalry. The principal towns are Kuka, the royal residence, Ngornoo, Dikoa, and Old and New Birnee. Most of them are populous, well built, and walled.

BORODINO, a small village of Russia, on the left bank of the Kolotcha, 2 m. above its junction with the Moskva, in the government and 70 m. W. S. W. of Moscow. It is famous for a battle between the French and Russians, Sept. 7, 1812. The French army, under Napoleon, numbered 125,000, while the Russian forces, commanded by Kutuzoff, Prince Bagration, and Barclay de Tolly, were nearly 160,000 strong. The battle commenced in the early morning, and raged with great fury until 3 o'clock in the afternoon, when the Russians gave up the field and retreated. The total loss of the Russians was 52,000 men, and that of the French 30,000. The former, having retreated in good order, never acknowledged the battle as a defeat, and in 1839 raised a mausoleum on the field as a trophy of victory. The French call it the battle of the Moskva, and it gave Marshal Ney his title of Prince of Moskva. The actual battle field was on the opposite side of the Kolotcha from Borodino.

BORON, the characteristic combustible element of the acid contained in borax. In nature it is always met with in combination with oxygen. It is found in small quantities, and only in a few localities. It presents considerable analogy with silicon in its properties and its mode of combination, and like it may be obtained in two distinct modifications, the crystalline and the amorphous. Berzelius obtained boron by heating the borofluoride of potassium with an equal weight of potassium in a covered iron crucible. Boron as thus obtained is an amorphous, dull olive-green powder, which before it has been strongly ignited soils the fingers, and is dissolved by pure water in small quantity, forming a greenish yellow solution; from which, however, it is precipitated unchanged on adding a little solution of sal ammoniac. Boron is not oxidized by exposure to air, to water, or to solutions of the alkalis, whether cold or boiling. It is, however, easily oxidized when treated with nitric acid or with aqua regia. After exposure to intense heat in vessels from which air is excluded, it becomes denser and darker in color. It may be fused by the application of a heat still more intense than that required to melt silicon. As first obtained, boron exhibits a strong attraction for oxygen, and, if heated in air or in oxygen, takes fire below redness, burning with a reddish light and emitting vivid scintillations; it is thus converted superficially into boric anhydride, B_2O_3 , which melts and protects a portion of the boron. Mixed with nitre and heated to redness, it deflagrates powerfully. It is also oxidized when ignited with hydrate of potash;

and when heated with carbonate of potassium in fusion it sets carbon free, and forms borate of potassium. Pulverulent boron, like silicon, is a non-conductor of electricity. Boron may be obtained in the amorphous form in large quantity by the following method (Wöhler and Deville; Liebig's *Annalen*, cv. 67): 1,500 grains of fused boric anhydride are coarsely powdered and mixed rapidly with 900 grains of sodium cut into small pieces. The mixture is then introduced into a cast-iron crucible previously heated to bright redness; 700 or 800 grains of solid but previously fused chloride of sodium are placed upon the top of the mixture, and the crucible is covered. As soon as the reaction is over, the still liquid mass is thoroughly stirred with an iron rod, and poured while red hot, in a slender stream, into a large and deep vessel containing water acidulated with hydrochloric acid. The undissolved pulverulent boron is then collected on a filter and washed with acidulated water till the boric acid is got rid of; after which the washing is continued with pure water till the boron begins to run through the filter. It must finally be dried upon a porous slab without the application of heat.—*Crystallized Boron*. In order to convert the amorphous into the crystallized form, the following method may be adopted: A small Hessian crucible is lined with the pulverulent boron made into a paste with water, and the boron is pressed in strongly, as in the ordinary mode of lining a crucible with charcoal. In the central cavity a piece of aluminum weighing from 60 to 90 grains is placed; the cover is luted on and the crucible enclosed in a second, the interval between the two being filled with recently ignited powdered charcoal. The outer crucible is next closed with a luted cover, and the whole exposed for a couple of hours to a heat sufficient to fuse nickel. The temperature is then allowed to fall, and when cold the contents of the inner crucible are digested in diluted hydrochloric acid, which dissolves out the aluminum; beautiful crystals of boron are left, generally transparent, but of a dark brown color. Numerous scales of boron are formed at the same time, in pale copper-colored, opaque, six-sided plates, which consist of an alloy of aluminum and boron, formerly erroneously called graphitoid boron. Crystallized boron has a specific gravity of 2.68; it assumes the form of transparent octahedrons belonging to the pyramidal system. These crystals when pure are nearly colorless, but they usually contain traces of foreign matter, which give them a pale yellow or red color; they refract light powerfully, and are hard enough to scratch the ruby, and even sensibly to wear away the diamond. Crystallized boron burns imperfectly in oxygen when heated to full whiteness, and becomes coated with a layer of fused boric anhydride. It however burns easily when heated to redness in dry gaseous chlorine, becoming converted into the

gaseous terchloride of boron. No acid or mixture of acids has any action upon the crystalline boron.—The atomic weight of boron is 10.9. The hardness of boron has suggested its use as a substitute for the diamond in cutting glass, for drills, and bearings of machinery; but the cost of production has hitherto prevented its extensive application.

BOROUGH. The origin of this term is uncertain. By some etymologists it is derived from *burgh* (Sax.), *burgus* (Lat.), a walled town, and thence applied to any association of families in a neighborhood, for the purpose of mutual protection. By others it is deduced from *borgh* or *borhæ* (Sax.), pledge, referring to the civil division into tithings or decennaries, hundreds, &c., in which the inhabitants composing the tithing or hundred were pledged for the good conduct of each other. It is probable that in an early period, when great disorder prevailed, protection was the principal object of the vicinage of houses which was denominated a borough. The term *villa*, from which is derived the modern *village*, originally signified a private country residence, but was afterward applied to a number of buildings placed near each other for the common safety of the inhabitants. It appears from "Domesday Book" that there were 82 boroughs in England, including cities, at the time of the Norman conquest. Though differing as to the extent of their franchises and mode of government, they were alike in two respects: 1, in having a fair or market; 2, in having a borough court independent of the hundred. A third particular afterward became the distinctive franchise of boroughs, viz., the right of sending burgesses to parliament. The original object of mutual defence was merged in another, viz., privileges of trade; and not long after the conquest the guild, which was an association of persons in a particular trade, became so intermingled with the original constitution of boroughs that it is difficult to distinguish the respective franchises belonging to each, and the guild merchant, which was a kind of incorporation or licensed association of all the trades, became substantially the borough, or at least became possessed of its franchises, government, and name. Membership of the guild thus became the principal mode of obtaining the freedom of the borough. The number of burgesses was by no means coextensive with that of the inhabitants; in fact, the boroughs were generally oligarchies, especially those which were created by charters after the conquest. The government was in many instances engrossed by a body self-constituted as the guild merchant, and in some cases even by a particular guild. Borough franchises were derived from charter or prescription (which was founded upon a supposed charter), and consisted at first of particular privileges, as that of a fair or market, of having a court, exemption from toll, and the like. Charters of incorporation were first granted in the reign

of Henry VI., although the ancient boroughs had in fact used the privileges peculiar to corporations, viz., of governing themselves, and of holding property in common. But from the period above mentioned, the history of boroughs belongs to the subject of municipal corporations, with the exception of parliamentary franchise. Before the act of 1832, known as the act for parliamentary reform, there were 171 boroughs in England, represented by 339 burgesses; from Scotland there were 15 members for boroughs, and from Ireland 36. By that act 56 English boroughs which had become insignificant in population were wholly disfranchised, 80 were deprived of one member each, and the right was given to 22 boroughs, which were before unrepresented, of returning two members each, and to 19 boroughs of returning one member each. The right of voting was also extended from a small privileged class to the citizens at large having certain qualifications. By the reform act of 1867 11 more boroughs were disfranchised; 23 were deprived of one member each, and 25 members were given to new boroughs and universities. Previous to the act last mentioned the whole number of representatives from boroughs in the English parliament was 337 from England and Wales, 23 from Scotland, and 39 from Ireland; but by that act 28 of this number were distributed among the larger counties, which were divided into districts for the purpose. In the whole kingdom the number of members for boroughs is now 366.—In the United States the term borough is applied to an incorporated village or town, but not to a city. In England it includes cities as well as villages, though in some old statutes the terms city, borough, and village are used distinctively.

BOROVITCHI, a town of Russia, in the government of Novgorod, on the Msta, 155 m. S. E. of St. Petersburg; pop. in 1867, 9,108. It has nine churches, two schools of a high grade, and several manufactories.

BOROVSK, a town of European Russia, in the government and 50 m. N. of the city of Kaluga, on the Protva; pop. in 1867, 8,826. It contains many churches, and near the town is one of the richest convents of the empire. There are extensive manufactories of sail cloth and of woollen goods, and there is an active trade in these articles, as well as in flax, hemp, and leather.

BORROMEAN ISLANDS, a group of four small islands in the gulf of Tosa, an arm of Lago Maggiore, in northern Italy. The group takes its name from the Borromeo family, in whose possession it has been for more than 600 years. The separate islands are called Isola Madre, Isola Bella, Isola dei Pescatori, and Isolino. They were little more than barren rocks prior to 1671, when Vitaliano, Count Borromeo, caused soil to be transported from the shores of the lake, terraces to be made, and all the trees and flowers to be planted which would grow in that climate. Isola Bella was most

Isola Bella, Borromean Islands.

richly adorned, being formed of ten successive terraces covered with beautiful trees and flowers, interspersed with statues and other works of art. At the west end is an elegant palace. Isola Madre, which is the largest, being 3 m. in circumference, consists of seven terraces, and has also a palace. Isola dei Piscatori contains a little village peopled with fishermen.

BORROMEO, Carlo, count, a saint and cardinal of the Roman church, born at Arona on Lago Maggiore, Oct. 2, 1538, died in Milan, Nov. 4, 1584. From his earliest childhood he was remarkable for his virtues. He studied civil and canon law in the university of Pavia, and took his degree in 1559. At the close of the same year his maternal uncle, Cardinal de' Medici, became Pope Pius IV., and successively made him archbishop of Milan, a cardinal, grand penitentiary, and president of the Roman council. He lived in the midst of great splendor, but in his own habits was temperate, studious, and devoted to the duties of his station. He instituted many reforms in the administration of affairs in the states of the church, and carried them into effect with vigor and wisdom. Through his agency the council of Trent was reopened, and its deliberations concluded. On the death of his elder brother he was urged, even by the pope himself, to leave the service of the church and take his position at the head of his family. This he refused to do, and determined to go to Milan and devote himself altogether to the interests of his diocese. He was greeted with great enthusiasm by the people, but before he had fairly addressed himself to the work before him was recalled to Rome by the death of the pope. His influence had much effect in securing the election of Pius V. He then returned to Milan, and set himself to work vigorously correcting abuses and reforming the manners of priests and people. He met with considerable opposition, and the Humiliati attempted to have him assassinated, in consequence of which the order was abolished, and its revenues were distributed among the poor. The cardinal instituted the order of Oblates, founded a great number of

schools, and is generally regarded as the first to establish Sunday schools. He associated with himself in his labors of reform a council chosen from the diocese at large, and put down with a resolute hand the pretensions of his suffragan bishops who resisted his measures of church discipline. He succeeded also in improving the secular government of Milan. His charities were munificent, not only his ecclesiastic revenues but his personal fortune and the works of art and ornaments of his palace being devoted to the relief of the poor and suffering. During the plague of 1576 he organized and superintended measures for the care of the sick and the burial of the dead. The magistrates had fled, and he had for a time the entire control of the city. The exertion, however, was too great for his physical strength, and his health soon became broken. His death was regarded as a national calamity, and was universally mourned throughout Italy. He was buried beneath the high altar in the cathedral of Milan, and his tomb became a shrine visited by pilgrims from all parts of the country. He was canonized by Paul V. in 1610. A collection of his works, including sermons, letters, the acts of his diocesan synods, and conferences delivered at the academy of the Vatican, under the title of *Noctes Vaticane*, appeared at Milan in 1599 (2 vols. fol.), and was republished with notes by Sax (5 vols. fol., Milan, 1747). The biography of St. Charles Borromeo has been written by Godeau, bishop of Venice (2 vols. 12mo, Paris, 1748), by Tournon (3 vols. 12mo, Paris, 1761), and by the Italian Guissano (1751). A life in English by E. H. Thompson was published in London in 1858. His statue was erected near Arona, and his festival is celebrated Nov. 4.

BORROMEO, Federico, count, cardinal, and archbishop of Milan, cousin of St. Charles, born at Milan in 1563 or 1564, died in 1631. He founded the Ambrosian library at Milan in 1609, and devoted to it most of his fortune. He sent Oligati to Germany, the Netherlands, and France, Ferrari to Spain, Salmaci to Greece, and Father Michael, a Maronite priest,

to Syria, to collect MSS. for it. He added to it a printing establishment, and founded academies, schools, and charitable institutions.

BORRAMEO, St. Charles, Sisterhood of, a religious association founded in 1652 by the abbé d'Estival, for educational and charitable purposes. It has its chief organization at Nancy, in Lorraine. A religious association of St. Charles Borromeo was founded in Bonn in 1846, for the distribution of Roman Catholic publications.

BORROMINI, Francesco, an Italian architect, born at Bissonne in 1599, died in Rome in 1667. He studied sculpture and architecture for about seven years in Milan, and then went to Rome, where he was employed under his kinsman, Carlo Maderno, in finishing St. Peter's. On the death of Maderno he continued at work under Bernini. He became capricious and fantastic in his designs, and killed himself in a fit of insanity.

BORROW, George, an English author, born near Norwich in February, 1808. He is the son of an officer in the army, and received his early education at various schools in England and at the high school in Edinburgh. At the age of 15 he was articled to a solicitor in Norwich, but soon turned his attention to philology, studying especially the language and habits of the gypsies, with whom he led a wandering life for some years. In 1833 he entered the service of the British and foreign Bible society, and was sent to Russia. Here he edited the New Testament in the Mantchou language, and published a book which he called "The Targum," containing metrical translations from 30 languages. He then went to Spain, where he mingled with the gypsies, translated the Gospel of Luke into their language, edited a translation of the New Testament into Spanish, and was thrown into prison for circulating the Bible. Having returned to England, he published in 1841 "The Zineali: an Account of the Gypsies in Spain," with a collection of their songs and a vocabulary of their language. In 1843 he published "The Bible in Spain," a narrative of his personal adventures. He afterward travelled for some time in Turkey and Wallachia. In 1851 he published "Lavengro: the Scholar, the Gypsy, and the Priest," a work autobiographical in form, but apparently containing much fiction. In 1857 he published "The Romany Rye," a sequel to "Lavengro;" and in 1862 "Wild Wales." He has also contributed much, both in prose and verse, to various periodicals.

BORSÁ, a village of Hungary, in the county of Máramaros, 45 m. S. E. of Szeged, at the entrance of a gorge leading into Bukowina; pop. in 1870, 5,503. In the neighborhood are some mines of gold, argentiferous lead, and copper.

BORSOD, a N. county of Hungary, bounded E. in part by the Theiss and the Hernád, and traversed by the Sajó; area, 1,370 sq. m.; pop. in 1870, 195,037, chiefly Magyars. The soil is mountainous or hilly in the northwest, and

level in the east and south. Cattle are reared in great numbers on extensive pastures. Borsod wheat is celebrated, and the county is called Little Hungary on account of its extraordinary productiveness in the principal staples of the country. The forests contain various kinds of timber and plenty of game. The vine culture is extensive. Minerals abound, and iron is worked to a large extent, and partly converted into steel. The county contains a number of large and over 170 small villages, and derives its name from that of Borsod, 5 m. S. of Szendrő, which contains a Protestant church and an old castle. Capital, Miskolcz.

BORY DE SAINT VINCENT, Jean Baptiste George Marie, a French naturalist, born at Agen in 1780, died in Paris, Dec. 23, 1846. He visited Mauritius and Bourbon in 1800, explored St. Helena and various other African islands, and on his return published *Essais sur les Îles Fortunées et l'antique Atlantide* (4to, Paris, 1803), and an illustrated *Voyage dans les quatre principales îles des mers d'Afrique* (3 vols. 8vo, 1804). He served in the French army under Davoust, Ney, and Soult, the last of whom subsequently employed him in the ministry of war. Exiled after the restoration, and hunted by the police through many of the states of Europe, he remained a fugitive till 1820, during which time he assisted in editing the *Annales générales des sciences physiques* at Brussels, and wrote his *Voyage souterrain*, describing the subterranean quarries of Maestricht. In 1829 he was chief of an official scientific expedition to the Morea and the Cyclades, and was the sole author of the botanical portion of the *Expédition scientifique de Morée* (1832 et seq.), besides writing with Chaudard the *Nouvelle flore du Péloponnèse et des Cyclades* (1838). He was in the war department in 1830, and rose to the rank of *maréchal de camp* in the corps of engineers. In 1839 he was appointed chief of a scientific expedition to Algeria. He was the principal editor of the *Dictionnaire classique de l'histoire naturelle*, writing nearly half of the first 10 volumes. He wrote two works on Spain, a history of microscopic animals, and *L'homme, essai zoologique sur le genre humain* (2 vols., 2d ed., Paris, 1827), the last being one of his most original productions.

BORYSTHENES. See DNEPR.

BOS, Lambert, a Dutch philologist, born at Workum, Friesland, Nov. 23, 1670, died Jan. 6, 1717. He was instructed by his father in Greek and Latin, and studied philology and oriental languages at Franeker, where he became professor of Greek. His principal works are *Ellipæ Græcæ* (1702) and *Vetus Testamentum ex Versione Septuaginta Interpretum* (1709; new ed., 5 vols., Oxford, 1805).

BOS, Bosch, or Bosco, Hieronymus, surnamed the Joyous, a Flemish artist, born at Bois-le-Duc after the middle of the 15th century, died in the early part of the 16th. Few particulars of his life are known. He excelled in painting demons, monsters, infernal scenes, and similar

fantastic subjects. Among his masterpieces are the "Temptation of St. Anthony," the "Flight into Egypt," the "Fall of the Angels," the "Adoration of the Kings," and the "Triumph of Death," mostly preserved in the art galleries of Spain, where Bos is believed to have spent a part of his life. His gloomy and wildly grotesque pictures and engravings were especially pleasing to Philip II.

BOSA, a town of the island of Sardinia, in the province of Cagliari, situated at the mouth of the river Termo; pop. 6,300. It is the seat of a Catholic bishop, has a college, and a considerable coral fishery.

BOSBOOM, Johannes, a Dutch painter, born at the Hague, Feb. 18, 1817. He studied under P. J. van Brée, and his best works are city views and church interiors, including "The Tomb of Engelbert II. of Nassau, in the church at Breda;" "The Great Church of Amsterdam," in the royal gallery at Munich; "Franciscan Monks chanting a Te Deum;" "The Holy Communion in a Protestant Church;" and "The Hall of the Consistory at Nimeguen." The last three pictures obtained a medal at the Paris exposition of 1855; and his "View in the Church of Alkmaar" and "Rotterdam Cathedral" appeared in that of 1867.

BOSC, Louis Augustin Guillaume, a French naturalist, born in Paris, Jan. 20, 1759, died there, July 10, 1828. He held public offices until the reign of terror, when he sought refuge in the forest of Fontainebleau. He visited the United States in 1796-'8, and contributed much toward diffusing in France a better knowledge of American natural history. He was for some time chief director of prisons, went on missions to Italy and to the wine districts of France, edited an agricultural cyclopædia, wrote extensively for various publications on natural history, with all branches of which he was singularly conversant, and became professor at the zoölogical garden of Versailles, afterward of Paris, and member of the academy. He acquired additional celebrity by his devotion to his former official chief Roland, and to Mme. Roland, whose memoirs he saved from destruction. After having been the tutor of Mlle. Roland, he became her guardian at the request of her parents, adopted her as his daughter, and recovered for her the confiscated property of her family. His chief works are: *Histoire naturelle des coquilles* (5 vols., 2d ed., Paris, 1824); *Histoire des vers et des crustacés* (2 vols., 2d ed., 1829); and his elaborate and renowned descriptions of the French wine districts.

BOSCAN (BOSCAN ALMOGABER), Juan, a Spanish poet, born in Barcelona before 1500, died in Perpignan about 1543. A patrician by birth, he was received at the court of Charles V. in Granada, served in the army, superintended for some time the education of the famous duke of Alva, travelled extensively, was converted to Italian forms of versification by Andrea Navagero, ambassador of Venice in Spain, and became the founder of a new Spanish school of

poetry, which has prevailed ever since. He wrote *Leandro* (1540), a long tale in blank verse after the model of Bernardo Tasso, on the basis of the "Hero and Leander" of Musæus. In the same year he translated Castiglione's "Courtier," which acquired celebrity as the most classical Spanish prose work of those days. His complete works were published by his widow in 1543, and consist of four books, the first containing poems of the old Castilian school, the second and third his poetry after Petrarch and other Italian models, and the fourth, "The Allegory," being the most original and celebrated of all. Among his works are poetical epistles after the manner of Horace, pastorals, and eclogues.

BOSCAWEN, Edward, a British admiral, third son of Hugh Boscawen, the first Lord Falmouth, born in Cornwall, Aug. 10, 1711, died near Guilford, Jan. 10, 1761. His mother was the daughter of a sister of Marlborough. Entering the navy at an early age, he was promoted to the rank of captain in 1737. In 1744 he captured a French frigate in the channel. He commanded all the land and naval forces sent to the East Indies in 1748, and the squadron employed against the French off Newfoundland and at Louisburg in 1758. The next year he gained a decisive victory over the French off Lagos, capturing three vessels and destroying two others. On his return to Spithead with his prizes and 2,000 prisoners, he received the freedom of the city of Edinburgh, and was made governor of the marine forces, with a salary of £3,000 a year, after having previously occupied the highest positions in the navy and the admiralty; and he also served for many years in parliament. Admiral Boscawen, one of the bravest of seamen, was styled by Horace Walpole the most obstinate of an obstinate family. Lord Chatham said: "When I apply to other officers respecting any expedition I may chance to project, they always raise difficulties; Boscawen always finds expedients."

BOSCH, Hieronymus de, a Dutch philologist and Latin poet, born in Amsterdam, March 28, 1740, died in Leyden, June 1, 1811. His *Poemata* (Leyden, 1803) are among the best Latin poems of modern times. His great work is the *Anthologia Græca* (4 vols., Utrecht, 1795-1810; 5th volume by Van Lennep, 1822). He was one of the founders of the Dutch institute for science and art, and curator of the Leyden university.

BOSCOVICH, Ruggiero Giuseppe, an Italian natural philosopher, born at Ragusa, May 18, 1711, died in Milan, Feb. 12, 1787. He was a member of the society of Jesus, a distinguished mathematician and astronomer, and the originator of a system of natural philosophy which regards the senses as immediately cognizant, not of matter itself, but only of the attractive and repelling forces which particles exercise upon each other. His *Philosophiæ Naturalis Theoria* (Vienna, 1758) expounded the doctrine of the propagation of pressure through solid

bodies, and threw much light upon the comparatively new doctrine of cohesion. He was for many years professor of mathematics in the Roman college, and for six years in the university of Pavia. Subsequently he became professor of astronomy and optics at Milan, where he established an observatory. He was employed in measuring a degree of the meridian, in correcting the maps of the Papal States, and in settling boundary questions. He was a member of the royal society of London and of many other learned bodies at home and abroad. After the abolition of his order in 1778, he spent several years in Paris as director of the optical department in the navy, receiving a pension of 8,000 livres. Vexed by the jealousy of D'Alembert and others, he returned to Italy, superintended at Bassano the publication of his complete works (5 vols., 1785), visited Rome, and finally retired to Milan. Among his writings on astronomy and other branches of physical science are *De Maculis Solaribus* (1736) and *De Expeditione ad Dimentiendo Secundum Meridiani Gradus* (Rome, 1755). His didactic poem *De Solis ac Lunæ Defectibus* (London, 1764) was translated into French by the abbé de Barruel (Paris, 1779). He published annotated editions with supplements of Noceti's works on the rainbow and the aurora borealis, and of Benedict Stay's poems on the Cartesian and other modern philosophical systems. His narrative of his journey from Constantinople to Poland appeared in French in 1772, in German in 1779, and in Italian in 1784.

BOSIO, Angiolina, an Italian vocalist, born in Turin, Aug. 20, 1829, died in St. Petersburg, Aug. 12, 1859. She belonged to a family of dramatic artists, studied in Milan under Catterino, made her début at Turin in Verdi's *I due Foscari*, and afterward sang with great success in Copenhagen and Madrid. Her first appearance in Paris was in Verdi's *Nabucco* in 1848; and she acquired celebrity there afterward in the same composer's *Luisa Miller* and in Rossini's *Moïse*. She visited Cuba and the United States in 1849, and after new triumphs in London and other capitals, accepted an engagement at the Italian opera in St. Petersburg, dying there from a cold in the zenith of her fame. Her voice was a pure soprano of power and sympathetic quality, and her style refined and polished, though she was deficient in vehemence. She was married to a gentleman named Xindavelonis.

BOSIO, François Joseph, baron, a French sculptor, born in Monaco, Italy, March 19, 1769, died in Paris, July 29, 1845. He studied under Pajou, but became to some extent a follower of Canova, was employed by Napoleon and by the successive Bourbon and Orleans dynasties, and was ennobled by Charles X. He executed the bass reliefs of the column on the place Vendôme, the equestrian statue on the place des Victoires, and many other works in France and Italy, among the best known of which are those connected with the mausoleum of the

countess Demidoff in Père-la-Chaise. He was a member and eventually director of the Paris academy of fine arts.

BOSJESMANS. See BUSHMEN.

BOSNA-SERAI, or **Serajevo**, a city of European Turkey, capital of the province of Bosnia, at the confluence of the rivers Milatchka and Bosna, in lat. 43° 52' N., lon. 18° 40' E., 560 m. N. W. of Constantinople; pop. about 60,000. It is surrounded by a wall of no considerable strength, and has a citadel with fortresses out of repair. The houses are mostly of wood. There are about 100 mosques, several schools, a number of Greek, and four Roman Catholic churches. The majority of the inhabitants are Moslems; the rest are Greeks, Catholics, and Jews. The Jews have a considerable part of the commerce. Bosna-Serai is a great entrepot of traffic between Turkey, Dalmatia, and Croatia; it exports leather, hides, wool, goats' hair, cattle, and smoked fish, and imports cotton and woolen stuffs, silks, lace, paper, salt, glassware, and jewelry. It has manufactures of leather, cotton, woollen, iron, copper, cutlery, and firearms. The city was founded by the Hungarians about 1263 under the name of Bosznavár. It derives its present surname Serai (palace) from a palace built in 1530 by Khosrev Bey, the governor of Bosnia. Prince Eugene captured the town in 1697, but was unable to take possession of the citadel.

BOSNIA (properly **BOSNA**; Turkish, *Bosna-maili*), the extreme N. W. province or vilayet of European Turkey, lying between lat. 42° 30' and 45° 15' N. and lon. 15° 40' and 21° 10' E., comprising Bosnia proper, Herzegovina, and Turkish Croatia; area estimated from 22,500 to 24,450 sq. m.; pop. about 1,100,000. It is bounded N. W. and N. by Austrian Croatia and the Military Frontier, E. by Servia, S. by Prizrend, Albania, and Montenegro, and W. by Dalmatia and the Adriatic. The surface is mountainous, the elevations ranging from 3,000 to 8,000 ft. A branch of the Dinaric Alps forms the watershed between the tributaries of the Danube and the rivers flowing S. The mountains consist chiefly of limestone of secondary formation, together with sandstone and shales of the carboniferous system; and it is also said that beds of coal are general throughout the country. The valleys are well watered. The chief rivers are the Save on the N. frontier, and its affluents the Unna, Verbas, Bosna, and Drina, and the Narenta, which flows into the Adriatic. The mountains are densely covered with forests. Sheep, goats, pigs, and poultry are raised in great numbers, but cattle and horses are neglected. The chief food is wheat and maize; barley, hay, hemp, &c., are cultivated to some extent. In Herzegovina tobacco, rice, oil, wine, figs, and pomegranates are produced. The culture of fruit is important, 300,000 quintals of prunes alone being produced annually. Fisheries are active, chiefly in the Bosna and Narenta rivers. The great mineral wealth of the country is undeveloped, but a few mines of

lead, iron, and mercury are worked. The chief manufactures are outlery and firearms. Among the exports are staves, timber, agricultural products, wool, honey, and wax. The total value of imports is about \$5,000,000, a great part of which consists of salt. Most of the merchandise comes from Constantinople and Sophia, to Bosna-Serai or Serayevo; but commerce is much impeded by bad roads, imposts, monopolies, and the sand banks and trunks of trees in the rivers, which render navigation almost impossible. The most important towns are the capital, Bosna-Serai, Banialuka, Travnik, Mostar, Fotcha, and Novi-Bazar. Of importance in a military point of view are the fortresses Sienitz, Vishegrad, near the frontier of Servia, Nikshity, near the frontier of Montenegro, Bielina, and Trebinje, the last on the main road leading to Ragusa. The towns are generally divided into three

Bosnians.

parts: the fortress, the city proper, surrounded by walls and having the gates closed at night, and the quarter occupied by the lower classes. Nearly the whole population belongs to the southern Slavs, who entered the country in the 7th century and dislodged the Illyrian race, which was probably identical with the Albanian. A remnant of the Albanian element, numbering about 80,000 souls, is found in the S. E. corner of the country. The prevailing language is a dialect of the Servian. The majority of the population are Christians, 431,000 belonging to the Orthodox Greek and 192,000 to the Roman Catholic church. There are about 5,000 Jews and 8,000 gypsies. The Mohammedans, 418,000 in number, are nearly all descendants of Slavs who embraced Islamism in order to preserve their estates, and include the wealthier part of the population, chiefly in the towns. A large portion of the commerce

of the country is in their hands. They comprise the beys, nobility, agas (land owners), and spahis, the descendants of the nobility whose ancestors were invested with fiefs at the time of the conquest. Their vassals pay them a tribute, and in war they form a cavalry of reserve. The Bosnians, especially the Christians, are hospitable, pious, and brave, but irascible and vindictive. The head of the family has a patriarchal jurisdiction over it, and his wife or son's wife has sole management of the house. The people are generally but little instructed; they have some knowledge of mechanics and of the elements of medicine, but scarcely any literature. There were formerly printing presses at Milesevo and Goradye, where church books in Slavic were printed as early as 1531.—Bosnia anciently belonged partly to Lower Pannonia and partly to Illyricum. In the 7th century the country was invaded by the Slavs. In the 12th and 13th centuries it belonged to Hungary. In 1339 it passed into the hands of the Servian king Stephen, after whose death it formed an independent government till 1370, when one of the chieftains, Ban Tvartko, seized the reins of power as king of Bosnia. At the beginning of the 15th century Turkey asserted its claims upon the province, finally annexing it in 1528; since then, however, the native nobility have frequently caused disturbances, especially in 1850 and 1851. The legal contingent of Bosnia in the Turkish army is 80,000, but it actually consists of only about 30,000. In 1857-'8 an insurrection of the peasantry took place at Tuzla against the exactions of the tax gatherers and beys. After an encounter with the troops they took refuge in Austrian territory, but returned upon a proclamation of amnesty. In 1861 another insurrection took place, and before it could be put down the war in Montenegro broke out, peace not being restored in Bosnia till after the suppression of the rebellion in the former country. A conference was held by the consuls of the European powers, but without any salutary effects. In May, 1868, an Austrian and Ottoman mixed commission met at Livno to define the boundaries between Bosnia and Dalmatia. During the administration of Osman Pasha, 1860-'68, Bosnia enjoyed peace and made considerable progress. A railway has been in course of construction since 1870 from Banialuka to the frontier near Novi, as the first section of the great line from the Austrian frontier to Constantinople.

BOSPORUS (Gr. *Βόσπορος*, ox-ford). **I.** Called by the ancients the Thracian, and by the Turks Istanbul Boghazi, the strait joining the Black sea and the sea of Marmora, between European and Asiatic Turkey; so named either from the legend of Io, who after being metamorphosed into a heifer passed over the channel, or because the strait is so narrow that an ox can swim across. It is about 16 m. long; its greatest width is about 2 m., and its narrowest part, near the middle, only a little

Castles of Europe and Asia.

over $\frac{1}{2}$ m. There are in this channel surface currents and undercurrents, the former flowing southward except during the prevalence of S. winds, and the latter flowing northward to the Black sea. In the narrowest part the current is very strong. Here are the castles of Europe and Asia, Rum-ili Hissar on the European side, built by Mohammed II. in 1451, and Anadolu Hissar on the Asiatic side, previously erected by Mohammed I. The sides of the channel are steep wooded cliffs, studded with ruins of all ages and gay buildings of the present day. According to tradition, confirmed by geological testimony, this strait was formed by the bursting of the barriers of the Black sea. It was anciently and is still famous for its extensive tunny fisheries. Constantinople and Scutari lie on the opposite shores of the southern entrance. From the former city the strait is frequently called the strait of Constantinople. **II.** Called by the ancients the Cimmerian, and now the strait of Kertch or Yenikale, formerly of Kaffa or Feodosia, the strait connecting the Black sea and the sea of Azov. It is wider and shallower than that of Constantinople. **III.** An ancient kingdom, comprising the country on both sides of the Cimmerian Bosphorus, founded in 502 B. C. by the Archaeanactidæ, a native Cimmerian dynasty, who were succeeded about 440 by a Greek dynasty, beginning with Spartacus I. The capital was Panticapæum (now Kertch) in the Tauric Chersonesus (Crimea). Under a later Spartacus (353-348) the limits of the kingdom on the Asiatic side were enlarged, Theodosia (Kaffa), on the European, having been annexed under his predecessor, Leucon I., in 360. About 280 Leucon became tributary to the Scythians. These latter became so exacting

that Parysades II., the last of the Leuconides, placed himself under the protection of Mithridates the Great of Pontus, who defeated the Scythians, and after the death of Parysades took possession of Bosphorus and placed his own son Machares on its throne. After his death and that of his father (63 B. C.) the Romans appointed his brother Pharnaces to succeed him, and after his overthrow by Cæsar several other princes who professed to belong to the family of Mithridates. When the line became wholly extinct in A. D. 259, the Sarmatians took possession of the country. It later formed part of the Eastern empire till its conquest by the Khazars, and was afterward taken by the Tartars.

BOSQUE, a central county of Texas, bounded E. by the Brazos river, and watered by North Bosque creek, and other affluents of the Brazos; area, 905 sq. m.; pop. in 1870, 4,981, of whom 528 were colored. The surface is hilly or undulating; about one third of it is covered with forests of oak, live oak, and cedar. The soil is a dark loam resting on bases of hard blue limestone. The chief productions in 1870 were 38,665 bushels of wheat, 260,946 of corn, and 2,165 bales of cotton. There were 8,071 horses, 4,829 milch cows, 21,022 other cattle, 5,607 sheep, and 8,971 swine. Capital, Meridian.

BOSQUET, *Pierre Joseph François*, a French soldier, born at Mont de Marsan, Nov. 8, 1810, died Feb. 5, 1861. He was educated at the polytechnic school of Paris and the military school at Metz, and acquired distinction in Algeria, attaining in 1848 the rank of general of brigade, and was wounded in the campaign against the Kabyles in 1851. In the Crimea he had the command of the second division, and was prominent in the battles of the Alma and

of Inkerman, in the latter of which but for his succor the English would have been crushed by the Russians. As chief of the corps destined to cover the allied forces on the slope of the Tchernaya, he constantly displayed quickness, vigilance, and activity, and took part in the storming of the Malakhoff, after which he was made a senator and a marshal. In 1858 he was appointed commander of the S. W. military division, but, disabled by the wounds received at Sebastopol, he was obliged to refrain from active duties.

BOSSI, Giuseppe, an Italian painter, born at Busto-Arsizio in August, 1777, died in Milan, Dec. 15, 1815. He studied at the Brera academy and in Rome, and on his return to Milan became secretary of the academy of fine arts, and afterward president of that institution and of those of Venice and Bologna. In 1801 he won a first prize for a picture commemorating the conclusion of peace, and in 1805 he exhibited various works, the best of which was a large cartoon representing the Italian Parnassus, which is in the museum of Milan. For Eugène de Beauharnais he executed a celebrated copy of Leonardo da Vinci's *Cena*, and published in 1810, as the result of his investigations relating to this famous masterpiece, *Libri quattro sul Cenacolo di Leonardo da Vinci*. He also participated in the biography of Leonardo da Vinci, and left an unfinished work on Lombard painters and several poetical effusions. He greatly enlarged and improved the Brera museum and Ambrosian library, and in the latter was placed a monument to him, with a bass relief and a colossal bust by Canova, executed by order of the academy. He was regarded as one of the most eminent painters of the modern Lombard school.

BOSSI, Giuseppe Carlo Aurelio, baron de, an Italian poet and diplomatist, born in Turin, Nov. 15, 1758, died in Paris, Jan. 20, 1823. The son of a Sardinian count, he acquired the title of baron in the French service. He produced several plays in his youth, studied law, and after a short banishment in 1781 was employed in the foreign ministry and in diplomacy. He was Sardinian minister plenipotentiary in St. Petersburg in 1797, when Paul I. on hearing of the Sardinian-French treaty sent him his passports, after which he became very prominent as envoy to Napoleon, and finally, with Carlo Giulio and Carlo Botta, was one of the three administrators or triumvirs of Sardinia (called in France the three Charleses) during the unsettled period preceding the annexation to France. He joined the French service in 1805, and became prefect of the department of Ain, and afterward of La Manche. His devotion to the emperor during the hundred days caused him to be removed from office after the second restoration. It was mainly due to his influence that England, supported by Prussia, successfully interfered in Sardinia in behalf of the Waldenses. He was the first to give a dramatic fervor after the manner of Pindar to the Italian ode.

Among his lyrics, which have been collected in 3 volumes (Paris, 1799-1801; 2d ed., London, 1816), are *L'Indipendenza americana* (1785), *La Olanda pacificata* (in two cantos, 1788), and *Oromasia* (on the French revolution, 12 cantos, 1805-12).

BOSSI, Luigi, count, an Italian historian and archæologist, born in Milan, Feb. 28, 1758, died there, April 10, 1835. He studied jurisprudence and natural sciences in Pavia, and became Bonaparte's agent in Turin, and after the annexation of Sardinia to France keeper of the Italian archives. He was the author of over 80 works on archæological, scientific, and historical subjects, including *Storia della Spagna* (8 vols., 1821), *Istoria d'Italia* (19 vols., 1819-'23), *Introduzione allo studio delle arti del disegno*, and a volume of dramas, besides contributions to periodicals and academical annals. He also published an elaborate edition in Italian of Roscoe's "Life of Leo X." (12 vols., Milan, 1816-'17).

BOSSIER, a N. W. parish of Louisiana, bordering on Arkansas, bounded E. and S. E. by Dauchite river and Bistineau lake, and S. W. and W. by Red river; area, 1,066 sq. m.; pop. in 1870, 12,675, of whom 3,505 were colored. Bateau lake is in this parish. The chief productions in 1870 were 287,660 bushels of Indian corn, 11,422 of sweet potatoes, and 13,506 bales of cotton. There were 1,553 horses, 1,564 mules and asses, 2,788 milch cows, 4,401 other cattle, 1,917 sheep, and 9,994 swine. Capital, Bellevue.

BOSSUET, Jacques Bénigne, a French prelate, born at Dijon, Sept. 27, 1627, died in Paris, April 12, 1704. He came of a family of lawyers, received his early education at the Jesuit college of Dijon, and thence was removed to the college of Navarre in Paris, where he soon attracted attention by his rapid progress in learning and his eloquence. It was said that he had formed a matrimonial engagement with Mlle. des Vieux, but that it was broken off in order that he might enter the church, though they never ceased to be friends, and he eventually provided her with a country seat near Paris, where she spent the rest of her life, prolonged till nearly her 100th year. He was ordained in 1652, spent some time under the influence of St. Vincent de Paul at Saint Lazare, declined the directorship of the college of Navarre (which he assumed, however, at a later period), and accepted the modest office of canon at Metz, relieving his arduous life of study and controversy with the Protestants by preaching occasionally in Paris. The sermons which he delivered there in 1659 created a deep impression. He never repeated a sermon, and spoke with little preparation excepting a rough draft of the leading points of his discourse. His style was picturesque, dramatic, and at times abrupt; the flow of his language was easy, and his presence was magnetic. For many years, and especially from 1660 to 1669, he was frequently summoned to Paris to preach the Lent and Advent series, and for occasional solemn-

ties, addressing larger congregations and with greater effect than any other pulpit orator in that capital. Among his eulogies of saints, that of St. Paul is his masterpiece. He especially excelled in funeral orations, though he was too much inclined to idealize the subjects of his panegyrics. The most admired were those on Henrietta Maria, widow of Charles I.; on the great Condé; on Anne, princess Palatine; and above all, on the duchess of Orleans, whose misfortunes and whose mysterious death lent additional interest to his discourse. The oration which he delivered on the duchess de la Vallière's taking the veil was another of his fine efforts. In 1669 he received the bishopric of Condom, but he never entered upon its duties, and relinquished the title and revenues in 1670, when Louis XIV. intrusted to him the education of the dauphin. For the special instruction of his pupil he wrote his *Discours sur l'histoire universelle, De la connaissance de Dieu et de soi-même, and La politique tirée des propres paroles de l'Écriture Sainte*; the first showing the omnipresence of God in history, the second applying religious principles to philosophy according to the ideas of Descartes, and the third sustaining absolutism in politics. His *Exposition de la foi catholique*, said to have been written (1671) especially for the conversion of Turenne, weaned the latter and other eminent persons from the Reformed church. This work, translated into many languages, was sanctioned by two papal briefs (1678-'9), and by the Gallican clergy in 1682, and finally gave rise to the memorable conference between Bossuet and the Protestant divine Claude. In 1671 he was admitted to the academy; and having finished the education of the dauphin, he was named almoner of the duchess of Burgundy, and in 1681 bishop of Meaux. In 1682, in his opening address at the extraordinary convocation of the Gallican clergy, he attempted to reconcile his devotion to the absolute power of the king with that to the holy see, proclaiming the "indefectibility" of the latter, while contesting the infallibility of the pope personally. His influence resulted in the adoption of the four celebrated articles of the Gallican church. The fourth article, claiming that, "although the pope had the principal voice in matters of faith, his decisions were still not irrevocable, at least if they were not confirmed by the consent of the church," was regarded as an attack upon the supremacy of the pope, and exposed him to charges of heresy. His *Histoire des variations des Églises protestantes* (2 vols.), first published in 1688, though circulated in MS. since 1685, is his most important controversial work. He strenuously denounced the quietism of his friend Madame Guyon, as well as of his former disciple Fénelon, in his *Relation du Quietisme*, and procured the latter's removal from court and the condemnation at Rome of his *Maximes des saintes*. Though he was in friendly and protracted correspondence with Leibnitz (1691-

1700) on the subject of a treaty for the union of the Reformed and Catholic churches, and though his biographer, Cardinal de Bausset, claims for him the gratitude of Protestants, it is uncertain whether he did or did not countenance the revocation of the edict of Nantes, and the subsequent persecutions of the Protestants. His activity was prodigious; he attended to the affairs of his diocese and to his duties at the court, while engaged in controversies, in writing and preaching, and in works of charity and piety. The last two years of his life were spent in comparative retirement owing to a painful disease (the gravel) from which he died. He was called by La Bruyère one of the fathers of the church, and by Henri Martin the Cornelle of the pulpit, but was more generally known as the eagle of Meaux. He left an immense correspondence, including that with Leibnitz. Among his works not yet mentioned are his *Maximes sur la comédie*, condemnatory of theatres, and *Commentaire sur l'Apocalypse*, which he interprets as predicting the fall of the Roman empire. There are many more or less complete editions of his writings, and several new and complete ones are in progress. The oldest is that of 1747-'53, in 20 vols. Those of 1825 (60 vols. 12mo) and of 1885-'7 (12 vols. large 8vo) are regarded as among the best. The edition prepared by the Benedictines in 48 vols. (1815 *et seq.*) includes the *Histoire de Bossuet* (4 vols., Paris, 1814), by Cardinal Louis François de Bausset, who was also the biographer of Fénelon. Among his other biographers in France was Burigny (Paris, 1761), and in England, Charles Butler (London, 1812). The best biography is the *Histoire de J. B. Bossuet et de ses œuvres*, by Réaume (1 vol., Paris, 1869). New light is thrown upon his life and achievements by the *Mémoires et Journal sur la vie et les ouvrages de Bossuet* (Paris, 1856-'7), after autograph MSS., edited by the abbé Guettée, with an introduction and annotations of the abbé Le Dieu, who was Bossuet's secretary from 1699 to 1704. They represent Bossuet as genial in his manners, and always preserving his serenity of temper, excepting in his animosity against Fénelon.

BOSSUT, Charles, a French mathematician, born at Tarare, Aug. 11, 1730, died Jan. 14, 1814. He studied under D'Alembert, became his collaborator in the *Encyclopédie*, and was admitted to the academy in 1768, after which the king founded for him a chair of hydrodynamics. He published *Mécanique en général, Cours complet des mathématiques*, and *Essai sur l'histoire générale des mathématiques*. The last, published in 1802, was his masterpiece. He wrote also on navigation, astronomy, physics, and history, and prepared an edition of Pascal's works, with an essay on his life and writings.

BOSTAN, or **Al-Bostan** (Arab., the garden), a town of Asiatic Turkey, on the Sihun (Sarus), and on the N. side of Mount Taurus, 40 m. N. W. of Marash; pop. about 9,000. It is situated in a well watered and well cultivated

plain, whence its name. It contains several mosques, is surrounded by many villages dependent upon its authority, and trades extensively in wheat with the Turkomans. It is generally supposed that Bostan is on or near the site of the ancient Cappadocian city of Comana.

BOSTON, a game played by four persons, with two packs of cards. The cards are never shuffled; one of the packs is dealt, and the other cut alternately to determine the trump. The dealer gives five cards to each player twice, and three the last time around. If the first player can make five tricks, he says, "I go Boston;" and his competitors may overbid him by saying, "I go 6, 7, 8, 9, 10, 11, 12, or 13," as the hand of each may warrant. Should either of them fail to make the number of tricks he "bids" for, he must pay to each competitor a forfeit regulated by a card of prices prepared beforehand. Boston is the most complicated of all games of cards. It is said to have been introduced into France by Franklin, and was called after his native city.

BOSTON, the capital of the commonwealth of Massachusetts and of Suffolk county, the chief city of New England, and the seventh of the United States in point of population, situated in lat. $42^{\circ} 21' 24''$ N., lon. $71^{\circ} 8' 58''$ W., at the western extremity of Massachusetts bay. The city embraces Boston proper, East Boston, South Boston, Roxbury, and Dorchester. Boston proper, or old Boston, occupies a peninsula, joined to the mainland on the south by a narrow strip of land known as the Neck, which was once overflowed by the tide, but has been raised and widened. The surface is very uneven, and originally presented three hills, Beacon, Copp's, and Fort (whence the early name of the peninsula, Trimountain), the first of which is about 180 ft. above the sea. Fort hill has recently been levelled, while the elevation of Copp's hill has been much reduced. East Boston occupies the W. portion of the island formerly known as Noddle's island, but more commonly bearing the name of Maverick, from Samuel Maverick, who lived there in 1630. It is equidistant from old Boston and Charlestown, and has a hilly surface. South Boston extends about 2 m. along the S. side of the harbor, an arm of which separates it from Boston proper. Near the centre are Dorchester heights, which attain an elevation of about 130 ft. above the ocean, and afford a fine view of the city, bay, and surrounding country. The surface of Roxbury and Dorchester in many places is rugged and hilly. The original limits of Boston embraced but 690 acres; 1,700 acres were acquired by the addition of South and East Boston, and by filling the surrounding flats; 2,100 by the annexation of Roxbury; 4,800 by the annexation of Dorchester; and 880 by filling flats in other places; making the present area 10,170 acres. The city is connected with Charlestown by the Charles river bridge, 1,503 ft. long, and the Warren bridge,

1,390 ft. long; and with Cambridge by the West Boston bridge, which crosses Charles river from Cambridge street, Boston, and is 2,756 ft. long, with a causeway of 3,432 ft. Craigie's bridge, 2,796 ft. long, extends from Leverett street to East Cambridge; from this bridge another, 1,820 ft. in length, extends to Prison point, Charlestown. South Boston is reached by the Federal street bridge, about 500 ft. long, and the South Boston bridge, 1,550 ft. long, extending from the Neck to South Boston. These bridges are all free. The Western avenue, or Milldam road, has been constructed upon a substantial dam across the Back bay from the foot of Beacon street to Sewall's point, in Brookline. It is about $1\frac{1}{4}$ m. long, from 60 to 100 ft. wide, and is a popular resort for driving. Boston is unsurpassed in the beauty of its suburbs, which embrace the cities of Charlestown, Chelsea, Somerville, and Cambridge, and the towns of Revere, Brighton, Brookline, Winthrop, and others. These places contain many handsome residences of persons doing business in Boston.—The harbor is a spacious indentation of Massachusetts bay, the mouth of which lies between Point Alderton on Nantasket and Shirley in Chelsea. It embraces about 75 sq. m., and includes several arms, such as Dorchester bay, South Boston bay, and the embouchures of Charles, Mystic, and Neponset rivers. A part of Charles river is commonly known as the Back bay. There are more than 50 islands or islets in the harbor. Boston light stands on Lighthouse island. Its top is 98 ft. above the sea, and is fitted with a revolving light which can be seen at a distance of 16 m. Northerly from the lighthouse runs a chain of islands, rocks, and ledges, 8 m. long, to the Graves. George's island commands the open sea, and Fort Warren, a very strong fortification, is built on it, the island being national property. Castle island (so called from a fortress which was erected there in 1633, and which subsequently was rebuilt and called Castle William in honor of William III.) lies further up the harbor, and is the site of Fort Independence. Governor's island is a mile to the north of Castle island, and Fort Winthrop, an uncompleted fortification, stands there. This island passed into the possession of John Winthrop in 1632, and for a long time was known as "the governor's garden." It is still in the possession of the Winthrop family, except that portion of it which has been ceded to the national government. Long island, which also has a lighthouse, is large, and attempts have been made to render it a place of residence, but with little success. Deer island is now occupied by city institutions, and Rainsford island by state hospitals. On Thompson's island is the Boston asylum and farm school for indigent boys. The main entrance to the harbor is between Castle and Governor's islands; it is very narrow, and is defended by Forts Independence and Warren. Deer island, comprising 184 acres of upland and 84 acres of flats, Thomp-

View of Boston from the Harbor.

son's, Great Brewster (16 acres), Galloupe's (16 acres), and Apple islands (9½ acres) belong to the city.—The growth of Boston for two centuries was not rapid. There are no exact figures for her population during the first four generations of her existence. It is supposed to have been 7,000 at the close of the 17th century. In 1742 it was placed at 18,000, probably an exaggeration. In 1764-'5, during the administration of Gov. Bernard, the first colonial census was taken, and under it the population of Boston was returned at 15,520. Mr. Bancroft says the population was "about 16,000 of European origin" at the close of 1768; and Mr. Frothingham puts it at about 17,000 in 1774. If the returns under the census of 1764-'5 were correctly made, Boston was 40 years in doubling her population after that date. The revolution, and the troubles which followed it, retarded her growth. Down to 1790 Boston did not increase so fast in numbers as the colony, province, or state of which she was or is the capital. The population from that date is shown by the federal censuses as follows: 1790, 18,038; 1800, 24,987; 1810, 33,250; 1820, 43,298; 1830, 61,392; 1840, 93,383; 1850, 136,881; 1860, 177,840; 1870, 250,526. The increase during the last decade is largely due to the annexation of Roxbury in 1867, which now constitutes the 13th, 14th, and 15th wards, containing 34,772 inhabitants, and of Dorchester in 1869, now forming the 16th ward, with 12,259 inhabitants. The character of the population has much changed during the last 30 years. Formerly it contained but few foreigners. In 1870 there were 162,540 native, 87,986 foreign, 247,013 white, and 3,496 colored. Of the native population, 127,617 were born in Massachusetts; of the

foreign, 56,900 were natives of Ireland, 18,818 of British America, 5,978 of England, 5,606 of Germany, 1,795 of Scotland, and 615 of France. Of the total population, 17,487 over 10 years of age were unable to read and 23,420 over 10 years of age were unable to write; of the latter, 21,993 were foreign and 1,427 native-born.—The legal division of the city is into 16 wards, but usage has divided it into certain districts. North Boston, or "the North End," is the oldest part of the place, and still retains much of the irregular appearance that characterized it in colonial times. Many old buildings yet stand there, but change is steadily going on. The North End comprises the larger portion of the Boston which makes so grand a figure in our revolutionary history. West Boston is mostly new, and contains the "fashionable quarter" of the town. It lies between Canal street and the Common, and west of Tremont and Hanover streets. It contains many public edifices, among which are the state house, the city hall, and the building of the Boston Athenæum. Most of the houses are of brick or stone, and many are costly and elegant. It contains many historical sites. "The South End" included before the annexation all that part of Boston which lies to the south of Winter and Summer streets, and running to Roxbury, now known as Boston Highlands. South Boston was originally the N. E. part of the town of Dorchester, and was annexed to Boston in 1804, except Washington Village, which was annexed in 1855. It has increased rapidly, and its appearance is strikingly different from that of old Boston, being open, airy, and cheerful. It forms ward 12, and contains 19,880 inhabitants. East Boston dates from 1832. Together with the islands in the har-

bor, it forms ward 1, and contains 23,824 inhabitants. It is a place of much enterprise, and is united by the Grand Junction railroad with all the railroads that proceed from the city. The depot of the Grand Junction is connected with the wharves, which have great depth of water. The water frontage is almost 20,000 ft., and the wharves are the best in the city. Two lines of steamships for Liverpool have their berths there. Ship building is one of its most important branches of business. It has extensive elevators for transferring to vessels grain brought from the west in cars, and ample facilities for loading and unloading foreign steamers and for the reception and despatch of immigrants. During the six months ending with March, 1872, 14,558 cars with 189,187 tons of merchandise were received here, and 11,127 cars with 114,128 tons of freight were forwarded. During the same period more than 1,000,000 bushels of grain were received at the elevator, and 617,826 bushels were exported. A large portion of the city west of the Common, known as the Back Bay, consists of made land, and has already become the most beautiful and fashionable quarter. In 1852 the commonwealth began to fill in these flats, and the proceeds of sales of this made land up to January, 1872, amounted to \$3,591,514, and the total expenditure to \$1,547,220. About 500,000 feet of land still remain unsold, and it is expected that \$1,500,000 profit will be realized from the improvement. Extending westerly from the public garden through this district is Commonwealth avenue, which when completed will be $1\frac{1}{4}$ m. long with a width of 240 ft. Through the centre runs a long park with rows of trees, while on either side are wide driveways. Many of the finest churches in the city, as well as private residences, have recently been erected in this quarter; among the public buildings are those of the Boston society of natural history and the institute of technology. The streets here are wide, regularly laid out, and present a handsome appearance; but in the older parts of the city, especially in the North End and the West End, they are exceedingly irregular. Some are very short, many very narrow, and most of them very crooked. Great improvements, however, have been made in the older parts of Boston by widening and raising streets. The most important of these improvements were made in Tremont street, south of Boylston street, and in Hanover and Devonshire streets. After the great fire of 1872 the streets burned over were improved by widening and straightening. The principal thoroughfare for general retail stores is Washington street, which extends S. W. in a very irregular line from Cornhill to Roxbury, a distance of more than 2 m. An ordinance has been passed for its extension northerly. The district bounded by State, Court, Tremont, Boylston, and Essex streets may be regarded as the business section of the city. The finan-

cial centre is State street, the headquarters of the bankers and brokers. Pearl street has been the largest boot and shoe market in the world, while Franklin, Chauncey, Summer, and the neighboring streets are noted for the great establishments that make Boston the leading market of the country for American dry goods. Boston has 120 hotels, 13 markets, 70 public halls, and 16 free public baths, of which 5 are for females. Gas is furnished by 7 gas companies, and the streets are lighted by 5,505 gas and 1,192 oil lamps. The city in 1872 contained 27,457 dwelling houses, 2,670 stores, and 2,690 miscellaneous buildings. There are 257,568,351 square feet of vacant land applicable to building purposes, valued at \$31,546,300, and 78,061,539 square feet of marsh land and flats, valued at \$2,630,100.—The most celebrated public building is Faneuil hall, the "cradle of liberty," in Dock square, which has a his-

Faneuil Hall.

torical reputation, because of the meetings of the revolutionary patriots that were there held. Most of the Boston political meetings are held in it now, when they are meant to be of a comprehensive character. The building was erected in 1742 by Peter Faneuil, a gentleman of Huguenot descent, and by him given to the town. It was nearly destroyed by fire in 1761. Rebuilt, and enlarged in 1805, it now covers nearly twice its first area. The hall is 76 ft. square and 28 ft. high. It is adorned with portraits of eminent Americans, conspicuous among which is an original one of Washington by Stuart. Among the other paintings are a full length of Peter Faneuil (a copy), Healy's picture of Webster replying to Hayne, and portraits of Samuel Adams, John Quincy Adams, Edward Everett, Abraham Lincoln, and John A. Andrew. The room over the hall is used by military companies for drill. The basement, which formerly was a market, is now a series of stores. The state house, in Beacon

street, near the centre of the city, with its dome 50 ft. in diameter and 30 ft. high, 110 ft. above the hill on which it stands and 230 ft. above the water of the harbor, is the most

State House.

conspicuous edifice in Boston. It was commenced in 1793, when Samuel Adams was governor, and was finished and occupied in January, 1798. Its form is oblong, 173 ft. front by 61 deep. The land was purchased by the city of Boston of the Hancock family, and given to the state. It was then known as "Gov. Hancock's pasture." The view from the dome is very fine, as it includes the harbor with the ocean beyond, an immense extent of country in various directions, covered with towns and villages, and the Blue hills of Milton. The hall of the house of representatives, the senate chamber, the rooms of the governor and council, the offices of the secretary of state, state treasurer, adjutant general, and auditor, and the state library, together with some minor offices, are in the state house. Large additions have been made to the state house since 1852, for the accommodation of the government; in 1866-'7 it was remodelled inside. On the terrace in front of the state house are statues of Daniel Webster and Horace Mann. In the Doric hall, or rotunda, is a statue of Washington by Chantrey, placed there in 1828 by the Washington monument association. Here are also the battle flags borne by Massachusetts soldiers during the civil war, copies of the tombstones of the Washington family in Brington parish, England, a statue of Gov. Andrew, busts of Samuel Adams, Abraham Lincoln, and Charles Sumner, and many historical relics. The old state house was erected in 1748, and was for half a century the seat of government, being the building which is of such frequent mention in the revolutionary history. It is in Washington street, at the head of State street, dividing the latter, and

obstructing a beautiful view. It has long been devoted to business purposes, having been entirely remodelled. One of the most imposing specimens of architecture in the city is the city hall in School street. It covers 18,927 square feet, is built of the finest Concord granite in the Italian renaissance style with modern French modifications, and is surmounted with a Louvre dome. It was completed in 1865 at a cost of \$505,691. The city officials have commodious quarters here, while in the dome is the central point of the fire-alarm telegraphs. On the lawn in front of the city hall stands the bronze statue of Franklin by Greenough. The new post office, in Milk, Water, and Devonshire streets, the corner stone of which was laid Oct. 16, 1871, will be when completed the finest building in New England. Its architecture is of the most ornate character. It will be of the finest granite, four stories high, with a frontage of over 200 ft. in Devonshire street. Its cost will exceed \$2,000,000. The upper stories will be occupied by the United States sub-treasury. The post office was in the merchants' exchange in State street until the fire of 1872, when it was removed temporarily to Faneuil hall. The exchange, completed in 1842, at a cost, exclusive of the land, of \$175,000, was noted for its large size and massive architecture; but in consequence of the damage then received, it was decided to remodel it. The custom house is a large and costly granite edifice in State street, and was 12 years in building, 1837-'49, at an expense of \$1,076,000. It is of the Doric order, and is 140 ft. long from N. to S., 95 ft. through the centre, and 75 ft. at the ends. The form is that of a Greek cross. The porticos are 67 ft. long, and project 10 ft. on each side. They comprise 32 Doric columns, each 32 ft. high with a diameter of 5 ft. 2 in. The building is surmounted by a dome, the top of which is 90 ft. from the ground. The court house, also of granite, is in Court square. The state and municipal courts are held here, while the old Masonic temple in Tremont street is devoted to the use of the United States courts. The Suffolk county jail, in Charles near Cambridge street, completed in 1849, is 70 ft. square and 85 ft. high, with four wings. The exterior is of Quincy granite, and the remaining porticos are of brick, stone, and iron. No school building in the United States surpasses in general completeness that of the girls' high and normal school. It was completed in 1870 at a total cost of \$310,717, has a frontage of 144 ft. both on Newton and Pembroke streets, contains 66 separate apartments exclusive of halls, corridors, &c., and has accommodations for 1,225 pupils. The large hall in the upper story contains a valuable collection of casts of classical sculpture and statuary acquired by donations. Tremont Temple, in Tremont street, was erected in place of the building burned in 1852, which had been made from the Tremont theatre. The main hall is 124 ft. by 73, and is

50 ft. high, with galleries on three sides. Nearly all the concerts, lectures, fairs, readings, &c., given in Boston, occur in Tremont Temple, Horticultural hall, and the Music hall. In 1872-'3, 19 courses, embracing 205 lectures, were delivered in Boston. The Music hall, completed in 1852, is in the interior of a block, with entrances from Winter and Tremont streets. The main hall is 130 by 78 ft. and 65 ft. high, and has two tiers of galleries on three sides. It is adorned with Crawford's statue of Beethoven, a statue of the Apollo Belvedere, and three casts of eminent composers presented by Miss Charlotte Cushman. The great organ in the Music hall is the largest instrument of the kind in America, and ranks among the finest in the world. Its entire height is 60 ft., breadth 48 ft., depth 24 ft. It contains 5,474 pipes, of which 690 are in the pedal organ, and has 84 complete registers. It was constructed at Ludwigsburg in Germany, at a cost of \$80,000, by Walcker, the builder of the great organs of Ulm and Stuttgart, and was formally inaugurated Nov. 2, 1863. Horticultural hall, corner of Tremont and Bromfield streets, is a handsome structure of fine-grained white granite, beautifully dressed. The front is surmounted by a granite statue of Ceres, and is ornamented by statues of Flora and Pomona. The lower floor is occupied for business purposes, while the two halls are used by the Massachusetts horticultural society and for public lectures, fairs, concerts, &c. The Masonic temple, on the corner of Tremont and Boylston streets, a structure of fine light-colored granite, highly ornamental and unique in style, was completed in 1867. It has a front of 85 ft. in Tremont street, and is 90 ft. high, having seven stories above the basement, and, besides numerous smaller apartments, contains three large halls for masonic meetings. Odd Fellows' hall has lately been erected on the corner of Berkeley and Tremont streets. The building is of elegant design, constructed of Concord and Hallowell white granite, is four stories high, and covers 12,000 square feet. The hall of the Massachusetts charitable mechanics' association, constructed of dark freestone in a modification of the Italian renaissance style, at a cost, including land, of about \$320,000, is on the corner of Bedford and Chauncey streets. It is used by the Boston board of trade and the national board of trade. The depot of the Lowell railroad company will when completed be one of the largest and most ornamental railroad structures in the country. It will be of brick, with trimmings of Nova Scotia freestone, and will be 700 ft. long, with a front of 205 ft. in Causeway street. The train house will be spanned by an arch of 120 ft. without central support. Faneuil Hall market, popularly known as Quincy market, situated just E. of Faneuil hall, was completed in 1827 at a cost of \$150,000. It is of Quincy granite, 530 ft. by 50, and is two stories high. Washington market was erected in 1870 for the accommodation of the South

End, on the corner of Washington and Lenox streets. It is 250 ft. long, 120 ft. wide, and contains nearly 100 stalls. Among the most ornamental of the private edifices may be mentioned the "Sears building," corner of Court and Washington streets, constructed of gray and white marble in the Italian-Gothic style, at a cost, including land, of about \$750,000, and devoted exclusively to offices, banks, &c.; and the hotel Boylston, containing apartments for families, recently erected on the corner of Tremont and Boylston streets.—Boston contains 25 public parks and squares. The principal one, Boston Common, is a park of 48 acres, surrounded by an iron fence, erected in 1836 at a cost of more than \$100,000. The Common is considered to date from 1634, and by the city charter it is made public property for ever, and the city cannot sell it or change its character. The malls are spacious and shaded by magnificent trees, some of which were set out considerably more than a century ago. There are nearly 1,800 trees on the Common, which are kept in admirable order at a large annual expense. The "old elm" is regarded as the oldest tree in New England; it is represented on a map engraved in 1722, and is supposed to be as old as Boston itself. In the great branch broken off by the gale of 1860 nearly 200 rings could be easily counted. It was also mutilated by a high wind in 1869, and is now protected by strong iron bands and props, and an iron fence. One of the most conspicuous objects on the Common is a costly bronze fountain, known as the Brewer fountain, cast in Paris and set up at the expense of Gardner Brewer. The foundation for a soldiers' monument has been laid on Flagstaff hill, near the centre of the Common. The public garden, which was once a portion of the Common, is now separated from it by a part of Charles street. It comprises 21½ acres beautifully laid out, and contains a conservatory, an equestrian statue of Washington by Ball, a bronze statue of Edward Everett by Story, one representing Venus rising from the sea, and a monument to commemorate the discovery of ether as an anæsthetic. Besides the public statues already mentioned, there is one of Alexander Hamilton in Commonwealth avenue, and two in Louisburg square, respectively representing Aristides and Columbus.—Five city passenger railway companies have lines extending to all parts of the city and suburbs, and there is an omnibus line from Concord street to Charlestown. There are two ferries to East Boston—North ferry, from Battery street to Border street, and South ferry, from Eastern avenue to Lewis street. Communication with Chelsea is by the Winnisimmet ferry, popularly known as Chelsea ferry, established in 1631, and believed to be the oldest ferry in the United States. Eight lines of railroad terminate in Boston, viz.: the Fitchburg, the Eastern, the Boston, Lowell, and Nashua, the Boston and Maine, the Boston and Provi-

dence, the Boston, Hartford, and Erie, the Boston and Albany, and the Old Colony and Newport. By means of the Grand Junction railroad, the main line of the Boston and Albany is connected with the Fitchburg, Lowell, Eastern, and Boston and Maine railroads, and with the Grand Junction wharf at East Boston, which greatly facilitates the transfer of freight to and from vessels. There are numerous lines of steamers to the principal eastern ports of the United States and British America, while two lines ply between Boston and Liverpool. The harbor has 164 wharves, and will afford anchorage for 500 vessels of the largest class.—Boston early became distinguished for her commerce. In less than half a century after the foundation of the place, the Boston merchants traded not only with other parts of America and the leading nations of Europe, but with the Canaries, the coast of Africa, and Madagascar. Their wealth was the subject of remark to all visitors. The first vessel belonging to Boston, of American build, was the bark *Blessing of the Bay*, built at Mystic for Gov. Winthrop, and launched July 4, 1681. She was of 80 tons, and her first voyage was to Long Island and New York. The first ship built at Boston was the *Trial*, in 1644, which immediately made a voyage to Spain. The same year a fur company composed of Boston merchants was formed. During the year ending Dec. 25, 1748, 480 vessels entered the port, and 540 were cleared. A century earlier the arrivals of ships were only about one a month, but even then large quantities of country produce were exported, 20,000 bushels of corn being mentioned among the exports of 1645. After the revolution Boston rapidly attained to eminence in commerce. The number of foreign arrivals was 899 in 1791, and 2,985 in 1857. In 1806 it was 1,088, and but 88 in 1814, the last year of the second war with England. In 1871 Boston ranked next to New York in extent of imports, and third among the cities of the Union in the value of foreign commerce, New York being first and New Orleans second. The total value of the commerce for the year ending June 30, 1871, was \$68,068,914, the imports being \$53,652,225, domestic exports \$12,761,291, foreign exports \$1,450,398; 671 American vessels of 266,678 tons, and 2,843 foreign vessels of 569,431 tons, entered from foreign ports; and 566 American vessels of 205,775 tons, and 2,723 foreign vessels of 896,778 tons, cleared for foreign ports; 41 American and 85 foreign ocean steamers entered, and 40 American and 28 foreign cleared; 788 steamers and 468 sailing vessels entered in the coastwise trade, and 858 steamers and 1,207 sailing vessels cleared. There were belonging to the port 876 sailing vessels, with an aggregate tonnage of 315,966, and 57 steamers with a tonnage of 22,820; 166 vessels of 5,360 tons were employed in cod and mackerel fishing; 25 vessels of 4,732 tons were built during the

year. The imports from England amounted to \$22,941,579, and the exports to that country were \$4,127,916; imports from British America, \$2,139,473, exports \$2,896,827; imports from British India, \$4,206,474, exports \$285,523; imports from Cuba and Porto Rico, \$7,325,512, exports \$992,784; imports from Brazil, \$1,042,000; from China, \$1,953,066; from the Argentine Republic, \$1,902,752; from Italy, \$1,740,607; from Sweden and Norway, \$1,150,070; exports to Chili, \$888,237. The leading articles imported, with their values, were: brown sugar, \$7,329,133; hides and skins (not fur), \$3,158,524; dress goods, \$2,188,451; bar iron, \$1,962,116; cloths and cassimeres, \$1,864,289; molasses, \$1,627,502; fruits and nuts, \$1,349,858; raw hemp, \$1,201,148; rags, \$854,369; coffee, \$698,729; earthen, stone, and china ware, \$672,837; indigo, \$594,338; spices, \$400,000; wool, \$372,115; tea, \$245,382. The chief articles of export were: flour, \$1,467,748; bacon and hams, \$658,501; petroleum, \$529,470; household furniture, \$301,569; ice, 49,085 tons, valued at \$202,452. The ice trade is a Boston invention. It was originated by Frederick Tudor, who in 1806 shipped 180 tons to Martinique. For 20 years the losses were great, but success was finally won by talent and perseverance. Mr. Tudor had a monopoly of the trade for 80 years, when, its brilliant success having become known to all, he found competitors. It is believed that but for the ice trade the Calcutta trade of Boston never could have become important. Formerly this trade was very large, but it has within a few years considerably declined. Boston is the only city on the eastern seaboard in which no capitation tax is levied upon immigrants. This impost in other cities varies from \$1 50 to \$2 50 on each passenger. The number of arrivals in 1871 was 22,904; in 1870, 30,069; in 1869, 26,414; in 1868, 15,128. The domestic trade of Boston is specially large in boots and shoes, wool, cotton, dry goods, clothing, fish, flour, and grain. The annual sales of merchandise are estimated at \$1,200,000,000. The receipts of wool embrace about one third the entire clip of the country, while the average weekly sales amount to about 1,000,000 lbs. The imports of foreign wool for a series of years, as compared with the imports into New York, are as follows:

YEARS.	BOSTON.	NEW YORK.
	lbs.	lbs.
1868.....	17,871,813	47,571,920
1869.....	20,780,124	51,591,879
1865.....	14,292,412	32,561,580
1866.....	20,027,998	86,068,176
1867.....	12,075,890	19,838,869
1868.....	10,878,791	18,458,685
1869.....	19,934,832	21,670,480
1870.....	15,721,147	12,460,290
1871.....	83,098,521	89,411,513

The stock of foreign wool on hand in Boston Jan. 1, 1872, was 2,846,800 lbs.; 1871, 2,052,000 lbs.; 1870, 4,550,000 lbs.; 1869, 2,840,000 lbs.; 1868, 5,155,000 lbs.; 1867, 5,435,000 lbs. The amount of domestic wool on hand Jan. 1, for a

series of years, in the three leading wool markets of the country, was as follows:

YEARS.	BOSTON. lbs.	NEW YORK. lbs.	PHILADELPHIA. lbs.
1868.....	7,400,000	6,100,000	8,000,000
1869.....	11,850,000	11,200,000	5,500,000
1870.....	8,900,000	8,780,000	8,900,000
1871.....	6,725,000	7,070,000	4,779,000
1872.....	7,100,000	6,814,000	2,702,000

The receipts of cotton in 1871 were 318,000 bales, all of which, excepting about 8,000 bales exported, was for consumption in the manufacturing towns of New England. The number and value of packages of domestic dry goods exported from the city has been:

YEARS.	Packages.	Value.
1862.....	2,065	\$261,128
1863.....	2,068	48,447
1864.....	245	42,217
1865.....	841	58,584
1866.....	4,744	670,235
1867.....	10,822	1,084,966
1868.....	11,943	1,293,242
1869.....	6,665	720,834
1870.....	7,486	785,885
1871.....	11,254	979,659

The hides received in 1871 were valued at \$14,800,000; 1870, \$11,885,000; 1869, \$13,225,000; 1868, \$11,500,000. The value of the leather manufactured for the Boston market in 1871 was \$36,900,000, against \$33,038,574 in 1870; and the whole amount of sales for the year was \$53,479,000, against \$47,881,991 in 1870. The aggregate sales of boots and shoes for 1871 amounted to \$64,500,000, and for 1870 to \$63,188,255. In 1871 1,251,223 cases of boots and shoes (average value, \$66 75 per case) were shipped from the city; in 1870, 1,213,129 cases; in 1869, 1,182,704; in 1868, 1,041,472. The receipts of fish in 1871 amounted to \$4,199,872. The elevators of Boston have a capacity for 1,000,000 bushels of grain. During the year ending March 1, 1872, there were received 1,408,325 barrels of flour, 4,179,911 bushels of corn, 475,500 bushels of wheat, and 2,431,272 bushels of oats, a large portion of which was for foreign exportation.—According to the latest returns of the industry of Massachusetts, the chief manufacturing establishments of Boston were 49 cabinet ware factories, 38 manufacturing of machinery, 38 book-publishing houses, 89 printing establishments, 31 hat and cap factories, 30 bookbinderies, 29 manufacturing of watches, 28 of cars, carriages, &c., 17 of pianos, 17 of upholstery, 12 brass and 7 type and stereotype foundries, 9 glass factories, 4 of organs, melodeons, and harmoniums, 4 of paper collars, 3 of sewing machines, and 2 of chemicals.—There are 51 national banks in Boston, with an aggregate capital of \$49,400,000. The number of savings banks in 1871 was 16, with a total of 180,480 depositors, and deposits aggregating \$49,944,206. The two most extensive were the five-cent savings bank, which had 58,568 depositors and deposits amounting to \$9,984,068, and the provident institution for savings, with 33,528 depositors and deposits reaching \$12,405,954. In 1872 there were 87 insurance

companies, of which 6 were life, with a combined capital of \$28,632,778; while 92 insurance companies belonging to other cities had agencies in Boston.—The government is vested in a mayor (salary \$5,000), elected annually on the second Monday in December, a board of 12 aldermen, and a common council of 64 members, 4 from each ward. The police are appointed by the mayor and aldermen, and are under the immediate direction of the mayor and a police committee. There are 11 police districts, a chief, 11 captains, and 11 lieutenants. The maximum number of the police force is 500, of whom 60 are officers. In 1871, 10,837 disturbances were suppressed and 25,201 arrests made, 17,794 of foreigners; 15,089 arrests were for drunkenness, 2,213 for assault, 1,372 for larceny, 98 for robbery, 18 for house breaking, and 8 for murder. The amount of property reported stolen was \$60,018; amount recovered, stolen in and out of the city, \$71,159; fines imposed, \$60,370. There were 2,952 places where intoxicating drinks were sold—1,428 groceries, &c., 1,121 bar-rooms, 327 jug rooms, and 76 hotels. The whole number of persons taken into custody by the police was 17,107, of whom 15,089 were taken to the stations, and 2,018 were taken home. The fire department comprises a chief, 14 assistant engineers, and a secretary, all elected annually by the city council, and 450 members; their aggregate salaries amount to \$215,163. They are divided into 21 steam engine companies, 10 hose companies, and 7 hook and ladder companies. About 46,000 feet of hose are used, and there are 2,375 hydrants and 96 reservoirs where water can be obtained in case of fire. The number of fires in 1871 was 549; the losses by fire amounted to \$704,329, being \$297,722 on buildings and \$406,606 on stock; total insurance, \$534,991—\$168,757 on buildings and \$366,234 on stock. The fire-alarm telegraph is in charge of a superintendent and a corps of operators, who keep constant watch at the city hall day and night. Here is the central office to which alarms are transmitted from the signal stations or boxes, of which there are 146. From this office 42 bells and 55 gongs at their various locations on churches, school houses, engine houses, &c., are struck precisely at noon every day.—Boston long felt the want of a supply of water, but it was not till 1848, during the mayoralty of Josiah Quincy, jr., that the want was met, and water brought from Lake Cochituate, 20 m. W. of Boston. The lake covers 650 acres, and drains some 14,400 acres. Water is conveyed by a brick conduit 11 m. long to a grand reservoir in Brookline, and thence to distributing reservoirs in Boston, East Boston, South Boston, and the Highlands. Brookline reservoir covers about 23 acres, and has a capacity of nearly 120,000,000 gallons. The Chestnut Hill reservoir has just been completed at a cost of \$2,423,231. It is situated in the towns of Brighton and Newton, 5 m. from the Boston city hall and 1 m. from the

Brookline reservoir, covers about 125 acres, and has two basins with an aggregate capacity of 780,000,000 gallons. It is surrounded by a beautiful driveway, varying from 60 to 80 ft. in width, which cost \$169,471, and is a fashionable resort. Authority has lately been given to the city to take water from the Sudbury river, which will be connected with the reservoirs by independent mains. An important improvement was made in the Cochituate water works in 1869, by the construction of a stand-pipe in Roxbury, by means of which pure water is forced to the highest levels occupied by dwelling houses throughout the city. The base of the shaft is 158 ft. above tide level; the interior pipe is a cylinder of boiler iron 80 ft. long. The total cost was about \$100,000. Its capacity is adequate to the supply of the whole city; hence the reservoir on Beacon hill is no longer used. The gross payments for constructing, carrying on, and extending the Cochituate water works, from their commencement, Aug. 20, 1846, to April 30, 1871, amount to \$19,087,530; total income, \$9,867,638.—The total debt of the city at the close of 1871 was \$29,383,390, of which \$27,865,916 was funded and \$1,517,473 unfunded. This was classified as follows:

City debt proper.....	\$17,020,493 88
Water debt (net cost of works).....	9,570,896 64
War loans (outstanding).....	1,915,500 00
Roxbury loans (outstanding).....	692,000 00
Dorchester loans (outstanding).....	154,500 00
Total.....	\$29,383,390 52

The means on hand for the payment of this debt, Dec. 30, 1871, were funds in the hands of the board of commissioners of the sinking fund, amounting to \$10,771,231, and public land and other bonds in the city treasury pledged for the payment of the debt, amounting to \$998,930; total, \$11,770,162. Immediately after the great fire of 1872, the legislature authorized the city government to issue bonds to the amount of \$20,000,000 to meet the exigencies caused by the fire. The total receipts into the city treasury on account of the city for the year ending April 30, 1871, amounted to \$20,773,594; expenditures, \$19,320,382. The chief items were:

	Expenses.	Income.
City hospital.....	\$101,290	\$5,686
Fire department.....	418,507	8,510
Health department.....	298,892	48,928
Police department.....	578,344	11,525
Public buildings.....	68,315	26,273
Public institutions.....	800,067	114,179
Schools and school houses.....	1,575,279	28,800
Streets.....	1,456,273	167,776
Water works.....	1,596,043	789,123

The whole amount of taxes assessed for the year 1870 was \$9,050,419, of which \$8,936,567 was assessed on real and personal estate, and \$118,852 on 56,926 polls. Of the whole amount, \$7,972,820 (\$13 65 per \$1,000) was for city and county, and \$963,747 (\$1 65 per \$1,000) for state purposes. The valuation and rate of tax for a series of years are as follows:

YEARS.	Real estate.	Personal estate.	Total valuation.	Rate per \$1,000.
1800....	\$6,901,000	\$3,194,700	\$15,095,700
1820....	21,687,000	16,602,200	38,289,200	\$4 00
1830....	39,960,000	22,626,000	59,586,000	4 05
1840....	60,424,200	34,157,400	94,581,600	5 50
1850....	105,093,400	74,907,100	180,500,500	6 80
1860....	163,891,300	112,969,700	276,861,000	9 50
1861....	167,682,100	105,073,000	275,760,100	9 50
1862....	168,638,000	112,579,000	276,217,000	11 50
1863....	169,624,500	122,552,700	302,577,200	13 80
1864....	182,070,300	150,877,600	332,444,900	15 80
1865....	201,628,900	170,263,875	371,592,775	18 00
1866....	225,767,215	180,595,130	415,362,345	15 50
1867....	250,687,700	194,358,400	444,946,100	12 80
1868....	287,635,800	205,337,900	498,578,700	13 70
1869....	332,051,900	217,459,700	549,511,600	15 80
1870....	365,593,100	218,496,300	584,089,400	15 80

The tax rate per \$1,000 in 1870 was \$22 50 in New York, \$18 in Philadelphia, \$15 in Chicago, and \$31 60 in Cincinnati. In 1840 the average amount of property owned by each inhabitant of Boston was less than \$900; in 1870 it had increased to an average of more than \$2,800.—The benevolent institutions of Boston are numerous, and effective in their operations. There are 62 societies which come under this special head. The Perkins institute and Massachusetts asylum for the blind, though it is largely aided by the state, and is in part the work of other places, is of Boston origin, and has derived much of its means from the liberality of Boston people. It has been under the charge of Dr. S. G. Howe since its opening in 1832, and has received 776 pupils. The number of inmates in 1871 was 162; number of instructors and employees, 40; average annual receipts for five years, \$78,497; expenditure, \$71,842. Indigent persons are admitted gratuitously. The Massachusetts school for idiotic and feeble-minded youth, at South Boston, also under Dr. Howe, has been very successful. It was opened in 1848, since which time 465 pupils have been received, and there were 106 inmates in 1871. The eye and ear infirmary, exclusively for the poor, is in Charles street, and is provided with everything necessary for the efficient treatment of the sick. The building and land cost \$54,000. The city hospital, opened in 1864, covers nearly seven acres of land, occupying the entire square bounded by Concord, Albany, and Springfield streets, and Harrison avenue. It consists of a central building and three pavilions, two of which are connected with the central building by corridors. Many patients are received and treated at the expense of the city, while others pay for these privileges. In 1871, 2,569 patients were treated within the hospital, in addition to 8,899 out patients. The Massachusetts general hospital, incorporated in 1811, is at the corner of Allen and Blossom streets, occupying a plot of four acres. The building is of granite, and has a front of 274 ft. and a depth of 64 ft., with a portico of eight Ionic columns. The general fund of the hospital, Jan. 1, 1872, amounted to \$888,258; the income of the corporation for the preceding year was \$211,802, and the ex-

penses \$238,458. These figures include the statistics of the McLean asylum for the insane at Somerville, which is a branch of this institution. In 1871 more than 1,500 patients were received in the hospital, about two thirds free of charge, and nearly 10,000 out patients were treated. The consumptives' home is a spacious mansion surrounded with ample grounds, at the junction of Warren street and Blue Hill avenue, Dorchester. The institution is of recent origin. It was founded by Dr. Charles Cullis, and is supported by voluntary contributions, which in 1871 amounted to \$55,000. During that year 185 patients were cared for at the home, and 757 have been received since its opening. The Boston farm school, for the relief and instruction of poor boys destitute of proper control, is on Thompson's island, and has accommodation for about 300 boys. Among the other benevolent institutions that are doing much good are the Baldwin home for little wanderers, the home for aged indigent females, and two inebriate asylums, the Washingtonian home and the Greenwood institute. The public charitable institutions are under the care of a board of directors elected by the city council; they have charge of the house of industry and reformation and the almshouse, situated on Deer island, and the house of correction and lunatic hospital, at South Boston. The whole number of inmates in the first three institutions, April 30, 1871, was 1,062, of whom 398 were females; total expenditures for the year, \$111,212; income, \$25,948. There were 409 inmates of the house of correction and 233 of the lunatic hospital; expenditures of the former for the year, \$82,001; income, \$75,599; expenditures of the latter, \$64,441; income, \$5,676. Galloupe's island is used as a quarantine station and for a smallpox hospital.—The schools of Boston have a high reputation. According to the report of the superintendent for the year ending Aug. 31, 1871, the number of persons in the city of school age (from 5 to 15) was 45,970, of whom 38,220 were attending school. The average number belonging to the day schools was 36,174, with an average daily attendance of 33,464; and there were 1,666 in the evening schools, with an average attendance of 1,037. There were 5 high, 37 grammar, and 327 primary schools, 11 evening schools, a school for deaf mutes, a kindergarten school, and 2 schools for licensed minors (boys licensed to sell papers and serve as bootblacks on the streets), making a total of 384 schools. The whole number of teachers was 990, of whom 850 were females. The high schools are the Latin school for boys, the English high school for boys, the girls' high and normal school, and the Highland and Dorchester high schools for boys and girls. The first named is well known as a preparatory school to Harvard university; its object is "to give thorough general culture to boys intending to pursue the higher branches of learning, or preparing for professional life." Much time is devoted to

the study of the languages, ancient and modern. There is also an evening high school. Music and drawing are taught in all grades of the public schools. The total expenditure for school purposes during the year was \$1,575,279, of which \$1,131,599 was for current expenses and \$443,679 for school houses and lots. The institute of technology was founded in 1861, and is "devoted to the practical arts and sciences." It is in Boylston, between Berkeley and Clarendon streets. The building, an elegant structure of pressed brick with freestone trimmings, is 150 ft. long, 100 ft. wide, and 85 ft. high. The institute receives one third of the grant made by congress to the state for the establishment of a college of agriculture and the mechanic arts. Its plan of organization includes a society of arts, a museum of arts, and a school of industrial science and art. In 1871 there were 264 students, from 13 states, and 18 instructors. Boston college is a Jesuit institution, with 10 instructors and 140 pupils, organized in 1863. The Boston university was founded in 1869 by the munificence of Isaac Rich, who bequeathed for that purpose the bulk of his estate, amounting to nearly \$2,000,000. The plan of the institution comprehends a general department of schools, which supposes on the part of the student a previous collegiate training, and a department of colleges. The former will embrace schools of theology, law, medicine, and universal science; and the latter, colleges of arts, natural science, philosophy and literature, agriculture, mining and engineering, navigation and commerce, pharmacy, dentistry, music, architecture, and painting and sculpture. The school of theology, the school of law, and the college of music are already in operation. The first named, the largest theological school in New England, was formerly the Boston theological seminary (Methodist Episcopal), organized in 1847. In 1872 it had 14 instructors, 94 students, and a library of 4,000 volumes. The school of law was opened in October, 1872, with 50 students. The college of music is intended to afford instruction to pupils advanced in the study and practice of music. Boston has numerous music schools, the chief of which, besides the one already mentioned, are the New England conservatory of music, in Music hall, the Boston conservatory of music in Tremont street, opposite the Common, and the national college of music in Tremont Temple, organized in 1872. The medical school of Harvard university is situated in North Grove street. It was established in 1783, and in 1871 had 25 instructors, 301 students, and a library of 2,000 volumes. The dental school of Harvard university, with 13 instructors and 27 students, is also situated in Boston. The New England female medical college, established in 1848, in 1871 had 5 instructors and 26 pupils. The Massachusetts college of pharmacy was established in Boston in 1867. In educational and literary institutions Boston is not surpassed by

any city in the United States. The public library, next to the library of congress at Washington, is the largest in the country. Joshua Bates, a wealthy banker of London, whose early life was passed in Boston, having offered the city \$50,000 toward the purchase of books if a suitable building should be provided, his offer was accepted in 1852 and an edifice was erected in Boylston street, opposite the Common, which was completed and delivered to the trustees Jan. 1, 1858. The cost of the land and building was \$365,000. Abbott Lawrence gave \$10,000 and Jonathan Phillips \$30,000 to the institution. In 1858 the library (2,250 volumes) of Nathaniel Bowditch was presented by his sons, and in 1860 the valuable collection (11,721 volumes) of Theodore Parker was received by bequest. The increase of the library has been as follows:

YEARS.	Volumes.	Pamphlets.
1852.....	9,698	961
1855.....	23,090	12,896
1860.....	97,886	27,881
1865.....	180,678	56,566
1871.....	179,220	69,746
1872.....	192,908	100,883

In 1871 the library of congress had about 206,000 volumes, the Astor library 140,538, and the New York Mercantile library 127,237. The increase of the Boston public library in 1871 was the largest ever reported, being 18,000 volumes and nearly 15,000 pamphlets; during the same period the library of congress increased 12,441 volumes and 8,000 pamphlets, the New York Mercantile library 11,416 volumes, and the Astor library 1,500 volumes. In that year the library of Spanish and Portuguese books and manuscripts of the late George Ticknor, more than 4,000 in number, was added to the public library. In 1872 the number of persons using the library was 42,453, and the number of books issued 380,343. The expenditures amounted to \$74,924, of which \$67,000 was appropriated by the city. The library is free to all, and books may be taken away; a branch with 6,767 volumes (included in the above figures), is in operation in East Boston. In 1872 a branch with 4,865 volumes was opened in South Boston, and preparations were made for opening another in Roxbury.—The Boston Athenæum dates from 1804, its germ being the Anthology club. The association was incorporated in February, 1807. The beautiful building now used by the Athenæum was completed in 1849. It stands on the S. side of Beacon street, between Bowdoin and Somerset streets. Its length is 114 ft., and its breadth is irregular; the height is 60 ft. The material is freestone. The first story contains the sculpture gallery and two reading rooms. The library is in the second story, and the picture gallery in the third. The building cost \$136,000, and \$55,000 was paid for the land. The privilege of using the library, which contains about 95,000 volumes, is limited to the holders of about 1,000 shares, but strangers

may have access. The funds of the Athenæum amount to more than \$250,000, besides the real estate, library, paintings, and statuary, which are valued at upward of \$400,000. The chief benefactors of the institution are: James Perkins, who gave it a house on Pearl street, which was used as a library, &c., for 27 years, and then sold for \$45,000; John Bromfield, who bequeathed it \$25,000; Samuel Appleton, who bequeathed it \$25,000; James Perkins, jr., who gave it \$8,000; Thomas H. Perkins, who gave it \$8,000; and T. W. Ward, who gave it \$5,080. Many other persons have given or bequeathed lesser sums, or books, or articles for the picture and sculpture galleries. The American academy of arts and sciences, incorporated in 1780, has its rooms and its library (about 15,000 volumes) in the Athenæum building. The magnificent building of the Boston society of natural history (incorporated in 1831), recently constructed at a cost of \$100,000, is on the corner of Boylston and Berkeley streets. The library contains 12,000 volumes; the valuable cabinet is open to the public for several hours on Wednesdays and Saturdays. The Lowell institute was founded by John Lowell, jr., who bequeathed \$250,000 to provide regular courses of free lectures. The most important libraries, in addition to those already mentioned, are the libraries of the American Congregational association, with 6,500 volumes and a fund of \$168,000; the Boston library society, with 19,000 volumes; the Handel and Haydn society, with 8,000 volumes (music); the Massachusetts historical society, founded in 1791, with 18,500 volumes; the mechanic apprentices' library association, with 6,000 volumes; the social law library, with 8,000 volumes; the state library of 82,000 volumes; and the young men's Christian association, with 4,610 volumes. The mercantile library, founded in 1820, had about 20,000 volumes, which were destroyed in the great fire of 1872.—The press of Boston is the oldest in the United States. The first journal regularly published in North America was "The News Letter," which was commenced April 24, 1704, by John Campbell, postmaster. It was published 72 years, ceasing in 1776, with British rule. The second paper was the "Boston Gazette," commenced in 1719, of which James Franklin was printer. In 1721 Franklin commenced the publication of the "New England Courant." Benjamin Franklin was an apprentice to his brother, and wrote for the "Courant" at the age of 16. The paper was for some time published in Benjamin's name. There are now (1873) 143 periodicals published in Boston, of which 9 are daily, 6 semi-weekly, 61 weekly (4 German), 1 bi-weekly, 4 semi-monthly, 51 monthly, 2 bi-monthly, 8 quarterly, and 1 semi-annual.—There are 150 churches in Boston, classified as follows: Baptist, 17; Christian, 1; Church of Christ, 1; Church of the Adventists, 1; Congregational Trinitarian, 22; Independent Congregational, 2; Congregational Unitarian, 27; Episcopal, 15; Evan-

gelical Adventists, 1; Freewill Baptist, 1; German Lutheran, 1; German Evangelical Reformed, 1; Swedish Lutheran, 1; Jewish synagogues, 4; German Methodist, 1; Methodist, 2; Methodist Episcopal, 18; Independent Methodist, 1; Presbyterian, 17; Roman Catholic, 17; Swedenborgian, 1; Universalist, 6. In the above are included several of the oldest churches in the United States. The oldest church edifice in the city is Christ church, Episcopal, in Salem street, founded in 1723. The Old South church was erected in 1729 in the same place where the first edifice of the society had stood since 1669. During the revolution it was occupied by British soldiers as a place for cavalry drill. Immediately after the great fire of 1872, it was leased for two years to the government for a post office, a new edifice for the use of the society being in process of construction on the corner of Dartmouth and Royalston streets. The last service was held in it on Nov. 17. King's chapel, on the corner of Tremont and School streets, has been used for divine service since 1754; the first edifice was erected there in 1689. Brattle Square church, in the walls of which was imbedded a cannon ball fired from Bunker Hill, June 17, 1775, was taken down in 1871. When completed, the cathedral of the Holy Cross on Washington and Waltham streets, begun in 1867, will be the largest and most ornamental church edifice in New England. The great tower at the S. W. corner will be 300 ft. high. There are two convents of Sisters of Notre Dame in Boston, St. Joseph's in South Boston and St. Aloysius in East Boston.—There are five theatres in the city, the oldest of which is the Boston museum, which was founded in 1841 and has occupied its present location in Tremont street since 1846. The Boston theatre, in Washington street near Boylston, one of the largest theatres in the United States, was opened in 1854. It is capable of seating 3,400 persons, with standing room for 1,000 more. The Globe theatre, in the same vicinity, was opened in October, 1868. The Howard Athenæum, in Howard street, and the St. James, in Washington street, are devoted to varieties.—The principal cemeteries used by Boston are the Mount Auburn, embracing 125 acres, in Cambridge and Watertown; Forest Hills, with a still larger area, in West Roxbury; Mount Hope, also in West Roxbury, 105 acres; Cedar Grove, in Dorchester, 46 acres; and Woodlawn, in the towns of Everett and Chelsea. There are in the heart of the city several burial grounds not now in use, but of great historical interest. The oldest of these adjoins King's chapel at the corner of Tremont and School streets. It is not known when it was first used for interments, but certainly as early as 1658. The "old granary burying ground," in Tremont street, between Beacon and Park place, was established in 1660, and contains the tombs of John Hancock, Samuel Adams, Paul Revere, Peter Faneuil, Samuel

Sewall, and the parents of Franklin. The Old North burying ground on Copp's Hill, which was first used for interments in 1660, still remains, and is protected by a high stone wall.—The first settlement of Boston was made Sept. 7 (O. S.), 1630, by a portion of the company which came from England that year with John Winthrop. The Plymouth pilgrims became acquainted with the peninsula in 1621. The only person residing there in 1630 was William Blackstone, or Blaxton, supposed to have been an Episcopal clergyman, and to have arrived about 1623. David Thompson and Samuel Maverick lived on two islands in what is now Boston harbor. It was by invitation from Blackstone that Winthrop and his associates removed from Charlestown to the peninsula, the excellence of the water at the latter place, and its abundance, being the chief inducement to the change. Blackstone soon left the colony, and his lands were purchased by the settlers. More than 50 years later, the last Indian claim to any portion of the territory was extinguished by the payment of "a valuable sum of money" to the claimants. The Indian name of the peninsula, according to Mr. Drake, the highest authority, was Mushawwomuk, Shawmut being merely an abbreviation. Some of the most noted of the colonists were from Lincolnshire, and it had from the first been their intention to give the name of Boston to their chief settlement, in honor of the Rev. John Cotton, vicar of St. Botolph's church, in the Lincolnshire Boston. The town records begin about 1634. The officers who subsequently were known as "selectmen" were in existence in 1634, but how the institution originated is unknown. The town meetings begin to be of importance at this date. The first grand jury of the country met at Boston, Sept. 1, 1635, and presented 100 offences. The church of Boston was much troubled about Roger Williams and his heresy, and finding him resolute, handed him over to the general court, which banished him. The Antinomian controversy broke out in 1636, the occasion of it being the action of Mrs. Anne Hutchinson, a woman of superior understanding, whose conduct greatly vexed the church. Free schools were established, the town paying liberally for their support, and Indians being taught gratis. Negro slaves were first brought to the town in 1645, much to the people's anger. A malignant disease raged in 1646. In 1651 the place is described by an eye-witness as very flourishing. Mrs. Anne Hibbins, a widow, said to have been a sister of Gov. Bellingham, was hanged in 1656 for witchcraft. When, two years later, the general court made a law for the punishment of Quakers, two of the Boston members dissented; but three Quakers were executed on the Common for having returned from banishment in defiance of the law. When Goffe and Whalley, the regicides, came to Boston in 1660, they were openly entertained by the principal inhabitants. Boston sullenly acquiesced in the

restoration, but Charles II. was not proclaimed there until 14 months after his arrival at London. Down to the date of the English revolution there was a constant antagonism, sometimes fierce in its manifestation, between the colony and the royal government, and it was most intensely felt in Boston. A description of Boston in 1671 shows that the town had much increased in numbers and wealth. The streets were large, and many of them paved with pebble stones. The buildings were fair and handsome, some being of stone, and one is mentioned that cost £3,000. The next year a report was made to the English government in which the number of families is stated at 1,500. When the general court voted £1,890 for the rebuilding of Harvard college, Boston paid £800. In anticipation of attacks from the Dutch, in 1672, extensive fortifications were commenced. "Philip's war" began in 1675, when Indian scalps were for the first time brought to Boston. They were Boston men who led the van in the famous attack on the Narragansett fort, and the town is said to have suffered nearly five times as much as any other place from the war. Liberty to establish a printing press in the town had been granted in 1674, with two ministers for censors; and a printing house was opened in 1676 by John Foster, a graduate of Harvard college. He printed the histories of the Indian wars written by Hubbard and Mather. In November, 1676, a fire occurred, which destroyed 46 dwellings, a church, and other buildings. A fire department was then organized, but not with much immediate effect; for in 1679 another conflagration swept away 80 dwellings and 70 warehouses. The loss was estimated at £200,000. During the reign of James II., and under the rule of his governors Dudley and Andros, the town lived under a tyranny. Yet James's "declaration of indulgence" was well received there, and the churches held a thanksgiving on its account. On April 18, 1689, the people of Boston rose against the government, and overthrew it. In no part of the British empire was the revolution of 1688 more warmly supported than in Boston. The witchcraft delusion raged in 1692 in Boston, as in other parts of New England. In 1695 the town's churches were much agitated by the discussion of the question whether it is lawful for a man to marry the sister of his deceased wife, and they decided it in the negative, which decision was followed by the enactment of severe laws by the general court against marriages of affinity. A list of all the streets, lanes, and alleys was made in 1708, and they were found to be 110 in number. Long wharf was commenced in 1710, running 800 feet into the harbor. A severe fire happened in 1711, burning 100 edifices, including the first church that had been erected in Boston, after the rude hut which had witnessed the primitive devotions of the earliest settlers. Several persons were killed, and others wounded, by the blowing up of houses, and a

number of sailors perished while piously endeavoring to save the church bell. Mail routes were at this date established at Boston, running both east and west. What is known as "the great snow storm" occurred in February, 1717. Some of the Scotch-Irish settled in Boston in 1720, and introduced the linen manufacture, which excited much interest, and was greatly encouraged, spinning schools being established. Boston had often been ravaged by the smallpox, and when in 1721 it again broke out virulently, Dr. Zabdiel Boylston determined to introduce inoculation. He encountered savage and malignant opposition, especially from medical men, but owing to the influence of Cotton Mather was allowed to proceed. Of 286 persons who were inoculated, only 6 died, while of the 5,759 who took the disease naturally, 844 died. As the population of Boston could not have been above 12,000, half the people were attacked. The first insurance office was established in 1724. The traffic in slaves prevailed to some extent in 1727, but the action of the town was strongly against it on many occasions. The town was divided into 12 wards in 1736. It was the scene of great riots in 1747, in consequence of some of the citizens having been impressed by Com. Knowles. The first theatrical performance was in 1750, Otway's "Orphan" being the piece selected. This led to the passage of a law which prevented any more dramatic exhibitions for 25 years. Nov. 18, 1755, 17 days after the great earthquake at Lisbon, the town was "dreadfully shaken" by an earthquake, perhaps the severest ever known in New England, by which great damage was done and much fright caused. March 20, 1760, a fire consumed 349 buildings, the entire property destroyed being valued at £100,000. Relief was sent to the sufferers from the other colonies and from England. The case of writs of assistance, which began the American revolution, was tried at Boston in 1761. James Otis so distinguished himself therein, that he became the most influential man of the town, and was said to have governed it for the next 10 years. At the first news of the intention of the British government to apply its revenue system comprehensively to the colonies, Boston assumed that determined stand in behalf of liberty which gave her so conspicuous a part in the birth of the republic. "The Boston massacre" happened March 5, 1770, when three persons were killed by the fire of the soldiery, and five wounded. The destruction of the tea in 1773 was pronounced by the tory governor of the province the boldest stroke which had been struck in America. (See UNITED STATES.) The passage of the Boston port bill was the practical retort of the imperial government to the proceedings of the Bostonians. But though the commerce of the town was for the time destroyed, and the independence of the local government was suspended for nearly two years, other places

refused to profit from Boston's sufferings; and her people received from all parts of the country warm sympathy and solid assistance. In 1775 there were about 4,000 British troops in Boston, and several armed vessels in the harbor. The battle of Lexington (April 19) roused the country, and in a short time Boston was beleaguered by a large American force, full of spirit, but destitute of all the other essentials of war. Their attempt to fortify and hold Bunker Hill, which commanded the town, resulted in a battle, June 17, in which the Americans were defeated from lack of ammunition, but which had on them and their cause the usual influence of a victory. Gen. Washington arrived in the besieging camp July 2, and assumed command the next day. The siege was prosecuted with all the vigor that could be displayed, but it lasted nearly a year. On the night of March 4, 1776, the besiegers seized and occupied Dorchester heights, which commanded both town and harbor. The English made preparations to recover the heights, but were prevented from assailing them by the severity of the weather, which was extreme until the 7th, by which time the American fortifications had been rendered impregnable to any force the enemy could bring against them. The British commander was compelled to abandon the place March 17. During the war Boston supported the policy that ended in the adoption of the federal constitution. In the material prosperity that followed the inauguration of the new government Boston largely shared. Her business increased, and her commerce was extended to almost every part of the world. She became distinguished also as a seat of learning, and for the number of persons eminent in literature or in oratory who were among her citizens or those of her suburbs. From 1830 to 1860 she was popularly regarded as the headquarters of anti-slavery and other reform movements. In 1822 Boston was made a city, 170 years after the change had been first talked of, and 118 years after the failure to have the place incorporated in 1709. In 1869 a monster musical festival, styled the peace jubilee, was held in Boston, in a wooden coliseum built for the purpose, 500 ft. long and 300 ft. wide, with a capacity for 50,000 persons. The chorus comprised 108 societies, with about 10,000 singers, and there was a band of nearly 1,000 instruments, with a battery of artillery, and 50 anvils beaten by 100 men. The festival opened June 15, and lasted five days. The receipts exceeded the expenditures by about \$50,000. A second festival projected by the originator of the first, Mr. P. S. Gilmore, was held from June 17 to July 6, 1872, under the name of the international peace jubilee. The coliseum built for this affair was 550 ft. long by 350 ft. wide, with an extreme height of 115 ft. The chorus comprised 165 societies with 20,000 voices, while the orchestra numbered 2,000. Representative military bands were present from France, Germany, England, and the United States marine

corps. The expenditures, which amounted to nearly \$600,000, exceeded the receipts by about \$150,000. In November, 1872, occurred a great conflagration, which, excepting the fire in Chicago the year before, was the most extensive and destructive ever known in the United States. It originated from an unknown cause in a large granite building, devoted chiefly to dry goods, on the corner of Kingston and Summer streets, and was discovered about 7 o'clock in the evening of the 9th. A moderate wind prevailed, and the flames, with wonderful rapidity, spread simultaneously in all directions, but chiefly toward the north and east. The fire continued till noon of the following day (Sunday), when it was brought under control, but again broke forth, in consequence of an extensive explosion of gas, about midnight, and lasted till 7 o'clock on the morning of the 11th. The district burned over extended from Summer and Bedford streets on the south to near State street on the north, and from Washington street east to the harbor. Within these limits, excepting a portion bounded by Milk, Devonshire, State, and Washington streets, the devastation was complete. The burnt district covered about 65 acres, and was the centre of the great wholesale dry goods, boot and shoe, wool, and clothing trades. About 800 buildings, many of which were of granite, five and six stories high, including some of the grandest business blocks in the United States, and occupied by about 1,800 firms, were entirely destroyed. The total loss, according to the most accurate estimate, was about \$80,000,000. The total loss by insurance companies was \$52,676,000, of which \$35,351,600 was sustained by Massachusetts companies. Very few public buildings or residences were destroyed. The number of lives lost did not exceed 15, while the suffering was mainly occasioned by the temporary loss of employment to about 25,000 working men and women.

BOSTON, a seaport town and parliamentary borough of Lincolnshire, England, on both sides of the river Witham, 6 m. from the sea, and on the Great Northern railway, 28 m. S. E. of Lincoln, and 107 m. N. N. E. of London; pop. of the town in 1871, 15,576. The two divisions of the town are connected by an iron bridge, of a single arch, 86½ ft. in span. Boston is noted for the neatness of its streets, is lighted by gas, supplied with excellent water from a distance of 14 m., and built almost entirely of brick. The most remarkable of its edifices is the parish church of St. Botolph, the largest without transepts in the kingdom, built in 1309, and having a tower 282 ft. in height, on the plan of that of the cathedral of Antwerp. This tower is surmounted by an octagonal lantern, visible at sea for nearly 40 m. A window of stained glass has been placed in this church in honor of the Rev. John Cotton, who was vicar of St. Botolph's and one of the first ministers of Boston in America. There are numerous charitable institutions, a

grammar school founded by Philip and Mary in 1554, three subscription libraries, a court house, spacious market houses, and commodi-

St. Botolph's Church.

ous salt-water baths, with pleasant grounds, established in 1830 for the use of the public. The manufactures consist of sail cloth, cordage,

Cotton Chapel.

leather, iron and brass work, &c. There is a considerable foreign trade, chiefly with the Baltic, whence timber, iron, hemp, and tar are imported, while large quantities of agricul-

tural produce are transported to London. A monastery was founded here in 654 by the Saxon St. Botolph, and destroyed by the Danes in 870; "hence," as Lombard says, "the name of Botolph's town, commonly and corruptly called Boston." There were several other ecclesiastical establishments, which were suppressed in the time of Henry VIII. During the civil war Boston was for a time the headquarters of Cromwell's army. Its decline subsequent to the 16th century was caused by the prevalence of the plague, to which its low situation particularly exposed it, and by the gradually increasing difficulty of the Witham navigation. The healthiness of the place has been improved by draining the surrounding fens, and its commercial prosperity has been in some degree restored by great improvements in the channel of the river. Vessels of 300 tons now unlade in the heart of the town. It is connected by canals and railroads with the principal towns in the north. Boston was the birthplace of Fox the martyrologist.—See "The History and Antiquities of Boston," &c., by Pishey Thompson (royal 8vo, Boston, 1856).

BOSTON, Thomas, a Scottish Presbyterian clergyman, born at Dunse in March, 1676, died at Ettrick, May 20, 1782. He was educated at Edinburgh university, and ordained minister of Simprin in 1699, whence he was transferred to Ettrick in 1707. He was a member of the general assembly and an uncompromising champion of the independence of the Scottish church. His works, which are strongly Calvinistic, were first published collectively in 1852 in 12 volumes. The best known are the "Fourfold State," the "Crook in the Lot," and a "Body of Divinity," which is esteemed of high authority in the Presbyterian church. He also left "Memoirs of his own Life and Times."

BOSTRA. See **BOZRAH.**

BOSWELL, James, the biographer of Samuel Johnson, born in Edinburgh, Oct. 29, 1740, died in London, June 19, 1795. His father, as judge of the court of session, bore the title of Lord Auchinleck, after the family estate in Ayrshire. James studied at the universities of Edinburgh and Glasgow, and early in life became a high churchman and a tory, although his father was a rigid Presbyterian and a whig. His early ambition for intimate relations with distinguished persons was strengthened on his first visit to London in 1760, and it was with difficulty that his father prevailed upon him to give up the notion of going into the guards, and to resume the study of law. After remaining for a short time at the university of Utrecht, he travelled extensively, visiting Voltaire, Rousseau, and other men of note. In 1766 he became a member of the faculty of advocates, but never practised, and soon afterward published a pamphlet concerning the celebrated Douglas cause, and one in 1774 containing a report of the decisions of the court of session on literary property. He was

much ridiculed on account of his enthusiasm for Paoli, whom he had visited in Corsica; but his "Account of Corsica, with Memoirs of General Pasquale di Paoli" (Glasgow, 1768; 3d ed., London, 1769), was praised by Hume, Johnson, Gray, and Walpole, translated into several languages, and was in a great measure the means of obtaining for Gen. Paoli marked attention and a pension of £1,200 on coming to England. In 1769 Boswell, after numerous love adventures, married a cousin, Miss Margaret Montgomery, an accomplished lady, with whom he lived very happily, and who died in 1789, leaving him two sons and three daughters. The great event of his life was his acquaintance with Johnson, formed in 1763, which ripened into intimacy. Through Johnson's influence he became in 1773 a member of the famous Literary club, where he met Burke, Garrick, Goldsmith, Reynolds, and other eminent persons. He went with Johnson to the Hebrides, and his narrative of this journey appeared in 1785, soon after his idol's decease; it contains valuable records of Johnson's conversation, and is exceedingly entertaining. Between 1773 and 1785 Boswell only enjoyed such snatches of Johnson's company and conversation as were afforded by occasional visits to London. These visits were but a dozen in all, and, added to the time spent in the northern journey, make the whole period during which the biographer enjoyed intercourse with his subject only 276 days. But the "Life of Johnson," which was published in 1791, is universally conceded to be the most entertaining biography ever written, and Macaulay declares it to be the best in universal literature. John Wilson Croker's famous edition of this work, including the "Journal of a Tour to the Hebrides," with numerous additions and notes, appeared in 1831 (5 vols.), and has frequently been reprinted. Boswell succeeded to his father's estate in 1782, and removed to London in 1786. In 1790 he stood for parliament, but was defeated. In addition to the works already mentioned, he published several political pamphlets and a series of papers in the "London Magazine," entitled "The Hypochondriac," expressive of the feelings of a man subject to a depression of spirits, such as was common to himself and to Dr. Johnson. A posthumous volume of "Letters of James Boswell, addressed to the Rev. W. J. Temple," was first published from the original MS. in London in 1856. In his letters published in 1785, Boswell says: "Egotism and vanity are the indigenous plants of my mind." This frank avowal of his foibles and his eccentricities only served to enhance the popularity which he acquired by his amiability and accomplishments, and by his generous appreciation of real merit.—His eldest son, Sir ALEXANDER, born Oct. 9, 1775, an intimate friend of Sir Walter Scott and a member of the Roxburghe club, was a contributor to "The Beacon," a bitterly personal Tory journal of

Edinburgh, and to its successor, "The Sentinel" of Glasgow. Having in the latter insulted Mr. James Stuart, a leading whig of Edinburgh, by an imputation of cowardice, he was challenged to a duel, in which he was mortally wounded, March 26, 1822, and died the next day. Mr. Stuart was tried for murder and acquitted. Sir Alexander was the author of a volume of "Songs, chiefly in the Scottish Dialect" (1803), "Clan Alpine's Vow" (1811), &c.—The second son, JAMES, was the author of a "Memoir of Edmund Malone" (1814) and editor of Malone's edition of Shakespeare, and also of several publications of the Roxburghe club. He died in London in 1822, in his 43d year; and it was immediately after returning from his funeral that Sir Alexander fought his fatal duel.

BOSWORTH, or Market Bosworth, a town and parish of Leicestershire, England, 12 m. W. of Leicester; pop. of the parish about 2,500. The town has a free grammar school, in which Dr. Johnson was an usher. On a moor in the vicinity the battle was fought, Aug. 22, 1485,

Bosworth Field—Monument over King Richard's Well.

in which Richard III. fell, and the wars of the roses were brought to an end. It was on the Crown hill near Bosworth that the crown was placed by Lord Stanley on the head of the earl of Richmond (Henry VII.) after the battle.

BOSWORTH, Joseph, D. D., an English philologist, born in Derbyshire about 1790. He was educated at the university of Aberdeen, and is a clergyman of the church of England. From 1829 to 1841 he was British chaplain at Amsterdam and at Rotterdam, afterward vicar of Walthe, Lincolnshire; and in 1858 became rector of Water Stratford, near Buckingham. His "Elements of Anglo-Saxon Grammar" (1823) and "Dictionary of the Anglo-Saxon Language" (1838) embody, according to the "Edinburgh Review," "the whole results of Anglo-Saxon scholarship." Among his other works are: "The Origin of the English, Germanic, and Scandinavian Languages and Nations;" "King Alfred's Anglo-Saxon Version of the Compendious History of the World by Orosius" (1856); and "The Gospels in Gothic of 360, and in Anglo-Saxon of 995, in parallel

columns with Wycliffe's Version of 1380, and Tyndale's of 1526" (1865).

BOTALLI, Leonardo, a Piedmontese physician, born at Asti about 1530. He was educated at Pavia, and went to France in 1561, where he acquired celebrity by his controversies with the faculty of Paris on the subject of bloodletting. In 1571 he was appointed physician in ordinary to Elizabeth, queen of Charles IX., and afterward to Catharine de' Medici. He wrote a number of important medical works, including *De Catarrho, De Lue Venerea, De Curandis Vulneribus Sclopetorum, De Via Sanguinis a Dextro in Sinistrum Cordis Ventriculorum, and De Curatione per Sanguinis Missionem*. His chief claim to distinction at present rests upon a singular error, namely, the description in the fourth of the works enumerated above of an exceptional case in which the *foramen ocale*, between the right and left auricles of the heart, remained open in the adult. Botalli supposed this to be a normal appearance, and described it accordingly as a natural opening, giving passage to the arterial blood into the left auricle; while in reality it exists, as a general rule, only in the fœtus, and when present in the adult does not allow the blood to pass through it. It is still known, however, as the "foramen of Botall."

BOTANY (Gr. *botânê*, a plant or vegetable), the division of natural science which treats of plants. The history and bibliography of the science will be treated in this article; for a general account of plants and their organism, see **PLANT**. As a plant in its typical form is composed of organs, as roots, stem, leaves, &c., which have each a part to perform in the life of the individual, a study of vegetable physiology must be the foundation of botanical knowledge. This important division of botany treats of these organs in their most intimate structure, a study only possible by the improvements in the microscope and in organic chemistry. Vegetable anatomy dissects the plant, opens the structure of the root, stem, bark, and leaves, or studies the special organs (organography), and the various forms which these organs assume for different functions (morphology), as where the leaf becomes a petal, a stamen, or a carpel, yet preserving all the while its identity. The botanist also examines the functions of all the organs, the order and mode of their development, and finally those derangements of plant life which are followed, as in the animal, by death of a part or of the whole (nosology). The vast number and variety of plants existing on the globe require a knowledge of some system of classification, and systematic botany supplies the want with a rigorous method by which all plants wherever found may at once be placed in a definite position in the order adopted. As plants are not scattered haphazard over the earth, botanical geography must be studied, and with this plant history, using the fossil remains of plants of former geological ages for the purpose. Botany may then

be applied to the wants of every-day life, as in agriculture, horticulture, or medical botany. Animals often exhibit a marvellous instinct in selecting medicinal herbs, and observation of their habits has often, even in the present time, led to valuable discoveries.—The fragmentary history we have of the study of nature by the ancients indicates a much greater knowledge than is recorded; for instance, in the well known paradox of the Greek philosophers that plants are only inverted animals—a statement that certainly required an extensive knowledge of the phenomena of vegetation. The collected descriptions of known plants, however, were very limited, the Hebrew Scriptures containing names of about 70 species which can be identified, besides some others. Hippocrates of Cos (about 400 B. C.) described briefly about 200 medicinal plants; Theophrastus, the pupil of Aristotle, describes about 400; Dioscorides (about A. D. 100) treats of about 600 species, of which fewer than 150 have been recognized. Pliny the Elder, in his *Historia Naturalis*, devotes 16 books to botany, describing almost 1,000 plants; but from his unscientific descriptions many cannot now be identified. The Arabian travellers added about 200 oriental plants to the 1,200 known before the 9th century. Jean Bauhin (born in 1541) wrote a universal history of plants, describing more than 5,000 species, illustrated by 3,577 figures; and later his brother endeavored to arrange the 6,000 plants then known. Linnaeus described in his first edition of the *Systema Naturæ* 7,300 species, and in the second 8,800; and at his death in 1778, 11,800 were known. The influence of his example on his many pupils rapidly increased the number of known plants, until in the time of Jussieu 20,000 had been described; and the number at present known is at least 100,000. With so vast a collection the botanist would be overwhelmed had he not some methodical arrangement; and as the history of the various devices invented by botanists to order and catalogue their rapidly increasing stores is an important part of botany, it may be considered, after a brief sketch of the labors and discoveries of the early botanists.—The ancients recorded many botanical observations which do not seem to have been productive of results; although Herodotus (book i., 193) mentions the fact that in Babylonia the flowers of the male palm were tied to those that bear fruit "in order that the fly entering the date may ripen it, lest otherwise the fruit fall before maturity: for the males have flies in the fruit, just like wild fig trees." The seeds of palms were still undiscovered. Aristotle wrote two books on plants, known only from Latin and Arabic versions. Theophrastus taught that there was no philosophical distinction between trees, shrubs, and plants. He noticed the difference between palm wood and that of trees with concentric rings, a point used as the first distinction in the classification of flowering plants only within the

last 60 years. The parenchyma and woody fibre were also clearly distinguished by this remarkable botanist. Musa and Euphorbus, Roman physicians, published botanical observations, and Pliny gives some interesting descriptions. For 1,700 years all botanical investigation was at a standstill. The Arabians, it is true, travelled and collected plants; Wahab and Abu Seid went to China and described the *tea* or tea plant; Masudi, Abulfeda, Batuta, and Averroes all made their contributions, and have generally been honored by having plants named after them. After the fall of Constantinople (1453), and the revival of letters consequent upon that event and the invention of printing, botanists were not satisfied with commentaries on Aristotle and Theophrastus, and made many new investigations. In Germany, Otto Brunfels first published good woodcuts of living plants in 1530; for those in the work incorrectly attributed to *Æmilius Macer* (1480), and even in that of *Pietro de' Crescenzi*, are all of inferior value. Leonhard Fuchs attempted to arrange and illustrate the known plants of his time. Rauwolf travelled in the western part of Asia and collected many new plants. Prospero Alpini, Venetian consul at Cairo, and Melchior Guilandinus, explored Egypt. The discovery of the West Indies in 1492, and the doubling of the Cape of Good Hope five years later, opened new and rich botanical storehouses. Conrad Gesner of Zürich (1516-'65) established genera from the flower and fruit, and his attempt at classification was published by J. Camerarius in 1586, in a synopsis of the commentary of P. A. Matthioli, physician to the emperor of Germany. Charles de l'Écluse (Clusius), director of the imperial garden of Vienna, described accurately and elegantly many new plants, and was the best botanist up to his time (1526-1609). Lobelius of Lille (1538-1616) was the first to distinguish monocotyledonous from dicotyledonous plants. Andreas Cæsalpinus of Florence, physician to Pope Clement VIII., established (1583) a system of classification from fructification, divided trees according to the direction of the germ, made the distinction of sex in dioecious plants clearer by giving masculine names to staminate, feminine ones to pistillate individuals, and, what proved of more permanent benefit, analyzed several of the important organs of vegetation. Among the botanists of this period were Jacobus Theodorus Tabernæmontanus, who reproduced the figures of more than 3,000 species which had been already described; his nephew, Joachim Jungermann; Fabricius Colonna, who first published delicate copperplates of plants; Ad. Zaluskiński, a Bohemian, who wrote on the sexes of plants and described the floral organs. Jean Bauhin of Basel, a pupil of Fuchs, laid out the garden of the duke of Würtemberg at Montbéliard, and wrote a universal history of plants, but described them less accurately than Cæsalpinus. His brother Gaspar tried to distinguish each species by a

brief description of its characteristics, and grouped all species into genera; and his system, with that of Cæsalpinus, was used by botanists for some years. War then put an end to botanical as to all other scientific progress in Europe; and although Maregraf explored and described the vegetable riches of Brazil, little advance was made until Leeuwenhoeck with the microscope (1682-1723) commenced the examination of the hitherto invisible structure of vegetables, and thus gave a new impulse to botany, which resulted in investigations pursued with great accuracy by Nehemiah Grew (born about 1628), and by the Italian Marcello Malpighi (born in 1628). These two naturalists laid the foundation of vegetable physiology as a science by carefully examining all the cells and tissues of plants and seeds; and, although in the great number of their discoveries they were both often misled, many of their investigations were of great importance. Several of the French academicians made further discoveries: Charles Perrault on the movement of the sap; Renaulme on the leaves as organs of transpiration, absorption, and nutrition; Dodart on the direction of growth; Lahire on the growth of trees. Van Helmont and John Woodward made experiments on the nutrition of plants. In 1676 Thomas Millington and Bobart discovered the fertilizing power of anthers, which Grew confirmed, establishing the sexes of plants. In 1694 R. J. Camerarius demonstrated this discovery, and three years later Booccone experimented with palms, acting on the suggestion of Herodotus. All these doubtless led Linnæus to his sexual classification. From the physiological botany which had at the time of Linnæus become so prominent, naturalists turned for a while to geographical botany, and many of the pupils of the great Swede were sent out as collectors. Solander explored Lapland, Archangel, &c., and circumnavigated the globe with Cook and Banks; Peter Kalm explored North America; Peter Löffling, Portugal, Spain, and New Spain; Hasselquist, Asia; Forskal, Arabia; Ternström, the East Indies; Osbeck, China; Solander, Surinam; others, various parts of Europe. Tournefort (1656-1708) travelled in southern Europe and western Asia; L. Feuillée travelled in Asia in 1690 and in America in 1705; Charles Plumier observed and collected plants in the Antilles, and A. Fr. Frezier in Spanish America. The Burmanns, father and son, described almost 1,500 new species from the East Indies, and Commelyn and his son described Malabar plants. Other distinguished botanical travellers are: Adanson, on the Senegal; Thunberg, successor of Linnæus, at the Cape of Good Hope; Kämpfer, in Japan; Ruiz and Pavon, in Chili and Peru; Mutis, in equatorial America; Jacquin, in South America; Swartz, in the Antilles; Aublet, in Guiana; João Loureiro, in Cochinchina; Commerson, almost all over the globe; Roxburgh, in Bengal; Desfontaines, in Algeria; Masson, at the Cape of Good Hope;

Ledru and Reidel, around the globe; Labillardière and Ventenat, in the Pacific islands; Du Petit-Thouars, in Madagascar; A. Michaux, in North America; Joseph Jussieu (1704-1779), among the Andes and the sources of the Plata; Alex. von Humboldt and Aimé Bonpland, in South America; Robert Brown, with the painter Bauer, in Australia; Ehrenberg, in Egypt, Abyssinia, Dongola, and Arabia (in which countries he collected 47,000 specimens); Lesson, in the Pacific islands; Baron Hügel, there and in the East Indies; Russegger, in Syria, Kordofan, and littoral Arabia; J. D. Hooker, in India and the Southern ocean; Leschenault de la Tour, in India; Griffith, in India; Victor Jacquemont, in eastern India; Siebold, in Japan; Ed. Rüppel and Schimper, in Nubia and Abyssinia; Otto, in the Cordilleras, on the Orinoco, and in North America; Aug. de St.-Hilaire, Spix, Martius, Moritz, and G. Gardner, in Brazil and Guiana; Schomburgk, in Guiana and Louisiana; Nuttall, in the United States; Tweedie, on the pampas in La Plata; Jo. Frazer and T. Drummond, in the United States; Bertero and Cl. Gay, in Chili; Allan Cunningham, in New Zealand and New Holland; Chamisso, in the Pacific and around the globe; Meyen, around the globe, which Charles Gaudichaud circumnavigated three times with Freycinet. Pallas, Baer, Schrenck, Ruprecht, Somelieu, Parrot, and Ehrenberg explored Russia. Among those who have made expeditions for botanical collections in the present generation are Vogel and G. Mann in Africa, Wright in Cuba and Texas, Brewer on the Pacific coast, Fendler in the S. W. United States, Horace Mann and Brigham in the Hawaiian islands, Fortune in Japan and eastern Asia, Remy in the Hawaiian islands, and Seemann in the Feejee islands.—*Classification of Plants*. Even before the collections of modern travellers had so immensely increased the number of known plants, it was found necessary to adopt some order or arrangement by which the recorded description of a species might be so placed that succeeding botanists could know what had been described. The classification adopted by Theophrastus into pot herbs and forest trees, cone plants, water plants, and parasites, and the more medicinal one of Dioscorides into aromatics, gum-bearing plants, eatable vegetables, and corn herbs, answered the purpose when botanists and described plants were few; but for the last century and a half botanists have been striving with the advance of their science to improve the classification of the rapidly increasing store of plants they had to study. Rivinus in 1690 invented a system depending on the formation of the corolla; Hamel in 1693, as Cæsalpinus had done before him, on the fruit alone. John Ray in 1703 published an amended natural system, separating dicotyledons and monocotyledons, but his work was little noticed. In 1720 Magnol arranged his system on the variations of the calyx and corolla. In 1735 Linnæus based his on the vari-

ations of the stamens and pistils, and this artificial system was at once adopted everywhere, and for many years was taught and used in all botanical classes in Europe and America. He devised the binomial system of nomenclature, denoting each plant by a generic and specific name. Although now entirely out of use, the Linnæan system is interesting as the best artificial one yet invented. Its outline is as follows:

MARRIAGES OF PLANTS.

Generation of plants.

Florescence.

PUBLIC, manifest, *phanerogamous*.

Flowers, visible.

Monoclinia (μόνος, one, κλίση, thalamus, couch).

Males and females on the same thalamus.

Flowers hermaphrodite: stamens and pistils in one flower.

Diffinity (no affinity).

Males not cognate.

Stamens altogether unconnected with each other.

Indifferentium (no subordination of males).

Stamens of indeterminate length.

- | | | | | |
|-----------------|-----|-------------------|--------|--------------------------------|
| 1. <i>Mon.</i> | (1) | 8. <i>Oct.</i> | (8) | } <i>-andria</i>
(manhood). |
| 2. <i>Di.</i> | (2) | 9. <i>Enne.</i> | (9) | |
| 3. <i>Tri.</i> | (3) | 10. <i>Dec.</i> | (10) | |
| 4. <i>Tetr.</i> | (4) | 11. <i>Dodec.</i> | (12) | |
| 5. <i>Pent.</i> | (5) | 12. <i>Icos.</i> | (20) | |
| 6. <i>Hex.</i> | (6) | 13. <i>Poly.</i> | (many) | |
| 7. <i>Hept.</i> | (7) | | | |

Subordination (certain males preferred to others).

Two stamens shorter than the others.

14. *Di.*

15. *Tetra.* } *-dynamia* (power).

Affinity.

Males related and cognate.

Stamens adhering among themselves or with the pistil.

- | | |
|-----------------------|-----------------------------------|
| 16. <i>Mon.</i> | } <i>-adelphia</i> (brotherhood). |
| 17. <i>Di.</i> | |
| 18. <i>Poly.</i> | |
| 19. <i>Syngenesia</i> | (births together). |
| 20. <i>Gynandria</i> | (wife-manhood). |

Diclinia (δύς, twice).

Males and females on distinct thalami.

Several males and females in the same species.

21. *Mon.* } *-æcia* (household).

22. *Di.*

23. *Polygamia* (many marriages).

CLANDESTINE, hidden, *cryptogamous*.

Flowers scarcely visible to the naked eye.

24. *Cryptogamia* (secret marriage).

From the 1st to the 11th class, which has 12 stamens, the number of the class coincides with that of the stamens. The 12th class, *icosandria* (20 stamens), differs from the 13th, *polyandria* (many stamens), not by the number, but by the insertion of the filaments, which is on the inner side of the calyx in the former and on the receptacle in the latter. *Didynamia* has 4, *tetradynamia* 6 stamens, 2 of which are shorter in each class. In the *monadelphia* the stamens have the filaments more or less united; in the *diadelphia* they are in two groups; in the *polyadelphia*, in several. In *syngenesia* the anthers (rarely the filaments also) are united. In *gynandria* the anthers are borne on the pistil, either sessile or with short filaments. *Monæcia* have the stamens in one flower, the pistil in another, but both on the same plant; while in *diæcia* the two forms of flower are on distinct plants, and in *polygamia* the pistillate and staminate flowers are on the same or different plants in the same species. These classes are divided into orders as follows: the first 13 classes according to the

number of their distinct stigmata, as *mono-, di-, &c., gynia*; the 14th by the seed (when covered, *angiosperma*; when naked, *gymnosperma*); the 15th by the form of the fruit, *siliquosa* (poddied), and *siliculosa* (with siliques); the 16th, 17th, 18th, and 20th by the absolute number of their stamens; the 21st and 22d by the absolute number of the stamens and their adherence (*monadelphia, syngenesia, gynandria*); the 23d by the distribution of the hermaphrodite or unisexual flowers (*mon-, di-, triacia*). The 24th class, *cryptogamia* (secret marriage), has four orders, *filices* (ferns), *musci* (mosses), *algæ* (seaweeds), and *fungi* (mushrooms). The 19th, *syngenesia*, has five orders: flowers all fertile, hermaphrodite (*polygamia equalis*); flowers radiate, disk with hermaphrodite florets, ray with pistillate (*polysuperflua*); disk with fertile hermaphrodite florets, ray with barren pistillate (*polyfrustranea*); disk with barren hermaphrodite florets, ray with fertile pistillate (*polyneccessaria*); each floret with its own calyx besides the common perianth (*polysegregata*), and also separated flowers, as the lobelia (*monogamia*). This artificial system is, then, founded on the differences, not on the similarities of plants, and does not tend to impart a knowledge of the structure of a plant beyond its stamens and pistils. Linnæus himself felt its deficiencies, and tried to work out what is called a natural system, which he declared to be the *primum et ultimum in botanicis desideratum*.—Bernard de Jussieu, in his catalogues of the gardens of the Trianon, adopted an arrangement of plants according to their natural affinities; and as he never published his method, it was left for his nephew Antoine Laurent (1748–1836) to give to the world the first natural system in his *Genera Plantarum secundum Ordines Naturales disposita* (Paris, 1789), a work containing descriptions of almost 20,000 species, and celebrated as a monument of wonderful sagacity and profound research, as well as for the eloquence and precision of its style. Various modifications of Jussieu's system have been adopted by succeeding botanists. Among them three methods deserve a more special mention, as the works in which they have been adopted are in constant use. De Candolle's *Prodromus Systematis Naturalis Regni Vegetabilis*, a description of all known species of plants, commenced in 1824 and now nearly completed, adopts the descending series, as it is called; that is, those plants which are considered most complete in their organization are first described, and the series ends in the lower cryptogams. The *Prodromus* is so much used by all working botanists that a brief synopsis of the arrangement therein followed may be given. The primary divisions are *vasculares* and *cellulares*. *Vasculares* or *cotyledonæ* are furnished with cellular tissue and vessels, and their embryo has one or more cotyledons. This includes: I. *Exogenæ* or *dicotyledonæ*, in which the vessels are arranged in concentric

layers, the youngest outside, and the embryo has opposite or verticillate cotyledons; II. *Endogenæ* or *monocotyledonæ*, in which the vessels are arranged in bundles, the youngest being in the middle of the trunk, while the embryo has a solitary or alternate cotyledons. The *exogenæ* are divided into *dichlamydeæ*, with calyx and corolla distinct, and *monochlamydeæ*, where the calyx and corolla form only one perianth. The *dichlamyds* are again divided into the *thalamifloræ*, in which the petals are distinct, inverted on the receptacle; the *calycifloræ*, in which the petals are free or more or less united, always perigynous or inserted on the calyx; and the *corollifloræ*, in which the petals are united into a hypogynous corolla, or not attached to the calyx. *Cellulares* or *acotyledonæ* are composed of cellular tissue only, and have no proper vessels, while the embryo has no cotyledons. This division includes the *foliaceæ* or plants which have leaf-like expansions and known sexes; and the *aphyllæ*, or plants which have neither leaf-like expansions nor (as was supposed when the method was published) sexes. John Lindley, in his "Vegetable Kingdom" (1846; 3d ed., 1868), adopts the ascending series. The number of orders is 303, and his classes are as follows:

- | | |
|--|---|
| I. <i>Thallogens.</i> | Flowerless Plants—Cryptogams. |
| II. <i>Acrogens.</i> | Stem and leaves indistinguishable. |
| | Stem and leaves distinguishable. |
| III. <i>Rhizogens.</i> | Flowering Plants—Phanerogams. |
| | Fructification springing from a thallus. |
| | Fructification proceeding from a stem. |
| † Wood of stem youngest in the centre; cotyledon single. | |
| IV. <i>Endogens.</i> | Leaves parallel-veined; permanent; wood of stem always confused. |
| V. <i>Dictyogens.</i> | Leaves net-veined; deciduous; wood of stem, when perennial, arranged in a circle with a central pith. |
| ‡ Wood of stem youngest on the circumference, always concentric; cotyledons two or more. | |
| VI. <i>Gymnogens.</i> | Seeds quite naked. |
| VII. <i>Ezogens.</i> | Seeds enclosed in seed vessels. |

The alliances proposed by Lindley are as follows: *Algales*, ex. seaweeds; *fungales*, ex. mushrooms; *lichenales*, ex. lichens; *muscales*, ex. urn mosses; *lycopodales*, ex. club mosses; *filicales*, ex. ferns; *glumales*, ex. grasses; *arales*, ex. arads; *palmates*, ex. palms; *hydrates*, ex. naiads; *narcissales*, ex. amaryllis; *amomales*, ex. maranta; *orchidales*, ex. orchis; *xyridales*, ex. spiderwort; *juncuales*, ex. bulrush; *liliates*, ex. lily; *alismates*, ex. alisma; *amentales*, ex. willow; *urticales*, ex. nettle; *euphorbiales*, ex. spurge; *quercuales*, ex. oak; *garryales*, ex. garrya; *menispermals*, ex. moonseed; *cucurbitales*, ex. melon; *papayales*, ex. papaw; *violates*, ex. violet; *cistales*, ex. rock rose; *malvales*, ex. mallow; *sapindales*, ex. soapwort; *guttiferales*, ex. clusia; *nymphales*, ex. water lily; *ranales*, ex. buttercup; *berberales*, ex. berberry; *ericales*, ex. heath; *rutales*, ex. orange; *geraniales*, ex. cranesbill; *silenales*, ex. pink; *chenopodales*, ex. amaranth; *piperiales*, ex. pepper; *ficoidales*, ex. mesembryanthemum; *daphnals*, ex. laurel; *rosales*, ex. apple; *saxifragales*, ex. saxifrage; *rhamnals*, ex. buckthorn; *gentianals*, ex. gentian; *solanals*,

ex. potato; *cortusales*, ex. primrose; *echiales*, ex. bugloss; *bignoniæ*, ex. trumpet-creeper; *campanulæ*, ex. aster; *myrtalæ*, ex. pomegranate; *cactales*, ex. cactus; *grossales*, ex. currant; *cinchonales*, ex. honeysuckle; *umbellales*, ex. carrot; *asarales*, ex. birthwort.—Stephan Endlicher published *Genera Plantarum secundum Ordines Naturales disposita* (Vienna, 1836-'40), the most important systematic work since A. L. de Jussieu's of 1789. His classes answer to Lindley's alliances. We subjoin a summary of his method, from his *Conspectus diagnosticus*:

Two regions contain all plants: 1. *Thallophyta* (Gr. *θάλλειν*, to pullulate, to green, grow, bloom, sprout), the *thalus* being either a leaf-branched tuft or frond, or flat-lobed mass of green matter upon the ground, a bed of fibres; and 2. *Cormophyta* (Gr. *κορμός*, Lat. *corpus*, truncus, stem, stalk), the *cormus* being the *lecus* of Du-Roi, Thouars, plateau of De Candolle, *bulbotuber* of Ker, and *bulbus solidus* of others; in short, a stem, whether subterranean or superterranean. The *thallophyta* (having no opposition of stem and root, no apical vessels nor sexes, but spores lengthened in all directions) he divides into two sections, viz.: 1. *Protophyta* (*πρότος*, first), born without soil, feeding by the surface, fructification vague; containing 2 classes, namely, *algæ* in 7 orders and 122 genera, and *Uchènes* in 4 orders and 57 genera. 2. *Hysterophyta* (*ὑστερος*, posterior, later), born on languid or dead organisms, feeding from within, developing all organs at once, perishing definitively; constituting 1 class, *Jungi*; birth hidden; sporidia none or within *asci* (*κύβητες*); in 5 orders, 27½ genera. In this region there are 16 orders and 458 genera. The *cormophyta* (having polar opposition of stem to root, vessels and distinct sexes in the more perfect individuals) he divides into 8 sections. The first section is *acrophyta* (*ἄκρος*, uppermost, highest, extreme, and *βῆμα*, I germinate, emanate, am bred); stem growing only at the top, lower part only food-bearing; comprising 8 cohorts, namely: 1. *Anophyta* (*ἀνω*, upward); no vessels; hermaphrodite; spores free within sporangia; with 2 classes, *hepaticeæ*, in 5 orders and 20 genera, and *musci*, in 8 orders and 26 genera; 2. *Protophyta*: bundles of vessels more or less perfect; no male sex; spores free within sporangia of one or more lodges; 5 classes; *a. equiseta* (horsetails), in 1 order, 2 genera; *b. filices* (ferns), 7 orders, 72 genera; *c. hydropterides* (water-wings), in 2 orders, 29 genera; *d. selaginæ*, in 8 orders, 111 genera; *e. zamia*, 1 order, *cycadaceæ*, 10 genera; 3. *Hysterophyta*: both sexes perfect; seeds without embryo, many-spored; parasites, with 1 class, *risanthæes* (root-flowering), in 5 orders and 14 genera. The second section is *amphibrya*: stalk growing peripherically; with 11 classes, viz.: *a. plumaceæ*, in 2 orders, *gramineæ*, grasses, 229 genera, and *cyperaceæ*, sedges, 47 genera; *b. euanthoides* (evergreen, against *βλαστός*, germ), in 5 orders, 83 genera; *c. helictis* (*ἕλκx*, pool, marsh, *βίος*, life), in 2 orders, 10 genera; *d. coronaria* (from the coronate perigonium), in 6 orders, 42 genera; *e. artionizeæ* (*ἄρτος*, bread, *ῥίζα*, root), in 2 orders, 17 genera; *f. ensæ* (*ἔνσις*, sword), in 7 orders, 110 genera; *g. gynandra* (female with male), in 2 orders, 855 genera; *h. scotamineæ* (Lat. *scotantina*, dainties), in 3 orders, 38 genera; *i. funiales*, in 1 order, *nauteæ*, 6 genera; *j. epidiciflora*, in 3 orders, 51 genera; and *k. principes*, in 1 order, *palma*, 62 genera. The third section is the *acramphibrya*: stem growing both at top and peripherically; divided into 4 cohorts: 1. *Gynanoperma*: ovules naked, fertilized immediately through the open fruit leaf or permeable disk, with 1 class, *coniferae*, in 4 orders, 28 genera; 2. *Apetaleæ*: no perigonium, or a rudimentary or simple one, calycine or colored, free or adhering to the ovary; with 6 classes: *a. pipertiteæ*, in 8 orders, 23 genera; *b. acutifolia*, in 3 orders, 10 genera; *c. juliflora* (Lat. *inulus*, catkin), in 15 orders and 1 suborder, 72 genera; *d. oleraceæ* (Lat. *olus*, a kitchen plant), in 4 orders, 60 genera; *e. thymeleæ* (*θύμηλη*, altar, flour), in 9 orders, 146 genera; *f. serpentaria*, in 2 orders, 8 genera; 3. *Gamopetaleæ*: perigonium double, exterior calycine, interior corolline, gamopetalic, seldom abortive; with 10 classes: *a. plumbaginæ* (Lat. *plumbum*, a disorder in the eyes, which some species were believed to cure), in 2 orders, 10 genera; *b. aggregatæ*, in 8 orders, 850 genera; *c. campanulæ*, in 5 orders, 53 genera; *d. caprifolia* (from climbing like a goat, Lat. *capra*), in 2 orders, 246 genera; *e. contortæ* (twisted), in 7 orders, 227 genera; *f. nucifloræ*, in 8 orders, 219 genera; *g. tubuliflora*, in 5 orders, 90 genera; *h. personatæ* (masked), in 7 orders, 318 genera; *i. petalanthæ*, in 4 orders, 70 genera; *j. bicornes*, in 2 orders, 88 genera; 4. *Dialypetaleæ* (*διαλύειν*, to dissolve, separate): perigonium double, outer calycine (with leaflets distinct or coalesced, free

or cognate with ovary, sometimes colored), inner corolline (parts distinct or seldom united by base of stamens, hypopery, or epigynous), sometimes abortive; with 23 classes, viz.: *a. discanthæ* (disk-flowering), in 7 orders, 252 genera; *b. corniculatæ*, in 8 orders, 77 genera; *c. polycaurpæ* (many-fruited), in 8 orders, 182 genera; *d. rhacodææ* (*ῥακῶδης*, pomegranate, here misspelled), in 5 orders, 201 genera; *e. nelumbia* (Cingales, *nelumbo*, water lily), in 3 orders and 1 suborder, 10 genera; *f. parietalæ*, in 13 orders, 94 genera; *g. peponifera*, in 8 orders, 83 genera; *h. opuntia*, in 1 order, *cactææ*, 9 genera; *i. caryophyllinææ* (*κάρπυον*, walnut, and *φύλλον*, leaf, from the appearance of the flower buds of pinks), in 4 orders, 108 genera; *j. columbinææ*, in 4 orders, 126 genera; *k. guttifera*, in 9 orders, 93 genera; *l. hesperides* (rockets, more fragrant in the evening, *ἑσπερος*), in 5 orders, 73 genera; *m. aceræ* (maples), in 5 orders, 86 genera; *n. polygalinææ* (*γάλα*, milk, believed to favor milk secretion when fed upon), in 2 orders, 16 genera; *o. frangulacææ*, in 7 orders, 100 genera; *p. tricoceæ*, in 3 orders, 123 genera; *q. terebinthinææ*, in 10 orders, 156 genera; *r. gruinaleæ* (like crabs, *gruinæ*), in 6 orders, 22 genera; *s. calyciflora*, in 8 orders, 102 genera; *t. myrtiflora*, in 2 orders, 172 genera; *u. rosiflora*, in 5 orders, 77 genera; *v. leguminosææ*, in 8 orders, 421 genera.

The *Genera Plantarum* of Hooker and Bentham, of which the first volume was completed in 1867, is the latest arrangement of orders and genera, and when finished will doubtless be for some time the guide in the classification of herbaria and local floras.—*Physiological and Anatomical Botany*. After the discovery of the microscope and the investigations of Grew and Malpighi, much study was devoted to the vegetable cell and the nature of cellulose. Mirbel, Dutrochet, Amici, Moldenhawer, Von Mohl, Unger, Frémy, and Schleiden have carefully observed the forms it assumes and the work it performs, Frémy distinguishing various kinds by chemical tests where optical tests failed. Schleiden calls the primitive utricle the cytoblast or germinating cavity; and Mulder in Holland and Schacht in Germany now lead those who consider all vegetation traceable from the cell-generating cytoblast. Pringsheim denies this. The movement of the sap was described by Corti in 1772, and Biot, De la Place, Fontana, L. O. Treviranus, Meyen, Cassini, Schultz, and Morren have published their observations on the circulation. The observers whose works may be consulted with profit for special phytotomic details are: on organic mucus, Brongniart, Mohl, Valentin; laticiferous tissue, Schultze (1839), Dippel, Hanstein (1863); protoplasm, Cohn, Unger, Max Schultze, K. II. Schultze; fibrous tissue, Purkinje, Morren; starch, Raspail, Fritzsche, Payen, Trécul, Nägeli; aleuron, Hartig, Trécul, Gris; color of plants, De Candolle, Mohl, Lawson, Morren; chlorophyll, Böhm, Mohl, Morren, Frémy, Gris, Verdeil; cell contents, Weddell, Schacht; epidermis, Schleiden, Brongniart, Weiss; stomata, the Krokera, father and son, Thomson, Lindley, Unger, Morren; bark and cork, Duhamel (*Physique des arbres*), Senebier, Pallini, Sprengel, Gaudichaud; stem, Daubenton, Desfontaines, Duhamel, Mohl, Gaudichaud, Mirbel, T. Hanstein (also on root and leaves); root, Trécul, Goldman, Link, Garreau and Brauwers, Decaise, Ohlert, Th. de Saussure, Macaire, Bouchardat, Chatin, Trinchinetti; leaf, J. D. Hooker, Braun, J. Rossmann, Steinheil, Mercklin, Wretschko, Trécul, Bonnet;

movements of plants, Runge, Desfontaines, Meyen, Brücke, Darwin; phyllotaxy, Schimper and Brown; floral organs, Dunal, Duchartre; anther, Purkinje, Fritzsche; pollen, Chatin, Wimmel, Nägeli, Hofmeister, R. Brown, Schleiden, Unger; ovary and ovule, Brongniart, Duchartre, Cramer, Grisebach, Tulasne, Deeke, Schacht, Henfrey, Radtkofer, Hofmeister; fruits, Lindley, Lestiboudois, Desvauz, De Candolle, Dumortier; vitality of seeds, De Candolle, Desmoulins, Girardin, Naudin; alimentation of plants, Dutrochet, Schumacher, Herbert Spencer, Hofmeister, Böhm, Hanstein, Hartig, Sachs, Payen, Vogel, Wittwer, Vierordt, Jac. Moleschott, Daubeny, Draper, Boussingault, Liebig, Grischow; respiration, Traube, Cornuinder, De Saussure, Gladstone. Of vegetable products: the proportions of the amylaceous bodies in plants (cellular tissue, inuline, dextrine, mannite, pectine, &c.) have been investigated by Bérard, Péligot, Braconnot, Eichof, Payen, and Pereira; oily substances, by Hartig, Mulder, Donders, Iljenko and Laskowsky, Playfair, Görgey, and Dumas; wax, by Brodie. The diseases of plants have been studied by Focke, Münter, Hartig (potato disease), Von Mohl (grape disease, 1852), and Liebig. Economic botany has been treated by Fée, Geiger, Reissech, Royle, Richard, Pereira, Endlicher, Nees von Esenbeck, Martius, Guibourt, and Schacht. Various classes of plants have received special attention from the following botanists: Cryptogams in general, Agardh, Persoon, Berkeley, Ehrenberg, Kützing, Decaisne, Thuret, Derbis, Nägeli, Cohn, Greville; algæ, Harvey, Johnstone, and Croal; fungi, Berkeley, Montague, Cordier, Tulasne, Kromholz, Sturm, Benerden, Badham, Cooke, Pringsheim; mosses, Hedwig, Sullivan; lichens, Tuckerman, G. von Holle, Leighton, Spierschneider, J. D. W. Bayerhofer; ferns, W. J. and J. D. Hooker, Moore, Eaton, Lower Baker; grasses, Munro, Kunth, Gray; palms, Martius, Seemann; liliaceæ, Redouté; conifers, Lambert, Richard; orchids, Bateman, Blume, Hooker, Moore, Darwin; cactaceæ, Engelmann; piperaçæ, Miquel; labiates, Bentham; rhododendrons, Hooker; geraniaceæ, Sweet, Andrews; heaths, Andrews. Local floras have been published as follows: United States, Gray, Torrey, Chapman, Brewer, Watson; Brazil, Martius, Saint-Hilaire and Jussieu, Humboldt, and Bonpland; Peru, Ruiz and Pavon; Chili, Bertero, Gay; Guiana, Schomburgk; West Indies, Grisebach, Wright, Larran, Descourtilles, Sloane; Antarctic, Hooker and Harvey; Pacific, Gray, Gaudichaud; Hawaiian Islands, H. Mann; Feejee and Samoan Islands, Seemann; New Zealand, Hooker; Australia, Hooker, Muller, Sweet, Bentham; Philippine Islands, Blanco; Hong Kong, Bentham; China, Loureiro, Hance; Japan, Thunberg, Siebold; Siberia, Gmelin, Maximovitch; India, Wight, Roxburgh, Wallich, Hooker, and Thompson; Java, Blume; Ceylon, Thwaites; Arabia, Forskal; Greece, Sibthorp; Italy, Gussone, Tenore, Bertoloni;

Austria, Jacquin, Kock, Reichenbach; France, Saint-Hilaire; Russia, Pallas; Lapland, Linnaeus; Sweden, Andersen; Denmark, Oeder; England, Curtis, Smith, Hooker, Bromfield, Sowerby, Greville, Bentham, Thornton, Babinston; Africa, Desfontaines, Hooker, Palisot de Beauvois, Harvey, Oliver. We give below an alphabetical list of the principal authors, native and foreign, who have applied themselves to the botany of the United States and of British America:

WILLIAM BALDWIN assisted Elliott in the sketch of the botany of South Carolina and Georgia.

BENJAMIN S. BARTON, professor of botany in Philadelphia, "Collections for an Essay toward a Materia Medica of the United States" 1798-1804; "Fragments of the Natural History of Pennsylvania" fol., 1799; "Progress of Vegetation," 1791; "Elements of Botany," revised, and with additions of British examples, &c., London, 1804; *Flora Virginica* (reaching only to the *tetrandria* of Linnaeus, but an enlarged and modified edition of the work of Clayton and Gronovius), Philadelphia, 1812; "Specimen of a Geographic View of Trees," &c., of North America between lat. 71° and 75° (incomplete).

L. C. BECK contributed toward the botany of Illinois and Missouri (not beyond the *monadelphia* of Linnaeus); "Botany of the United States north of Virginia," 1838; 2d ed., 1848.

JACOB BIGELOW, *Florula Bostoniensis*, 1814, '24, '40; "American Medical Botany," 1817-'21, 8 vols., 60 colored plates; "On the Forwardness of Spring in different parts of the United States," 1818.

J. A. BREERETON, *Prodromus Floræ Columbianæ* (of Washington), 1830.

W. H. BREWER, "Botany of the California Geological Survey," 1873.

BROWN, "List of Plants collected on the Coast of Baffin's and Possession Bay," London, 1819; *Chloris Melvillianæ*, 1828.

MARK CATESBY, "Natural History of Carolina, Florida, and the Bahamas," 2 vols. fol., 1743; also *Hortus Britannice Americæ*, treating of trees fit for England (also under the title of *Hortus Europe Americæ*), 1763-'7.

CHAPMAN, "Botany of the Southern United States."

J. CORNUTUS, a French physician, published a *Canadensium Plantarum Historia*, Paris, 1686.

M. CUTLER wrote an account of the vegetable productions of New England, 1765, probably the first essay of a scientific description.

J. DARBY wrote on the vegetable productions of the southern States, and (1841) a "Manual of Botany."

W. DARLINGTON, "Essay on the Development of the External Forms of Plants," compiled from Goethe, 1839; on *gramineæ*, as important to man; a *Florula*, 1826, and a *Flora Cæstrica* (of West Chester, Pa.), 1837; on "Agricultural Botany," and "Memorials of J. Bartram, H. Marshall," &c., Philadelphia, 1849.

DEWEY, on cartography, "Stillman's Journal," vol. vii.

A. EATON's "Manual of Botany for North America" on the system of Linnaus, 1st ed. in 1818, 8th in 1840 (in the last edition Wright cooperated), and some elementary books, marked an epoch in the progress of the science in this country.

A. ELLIOTT issued in numbers (1816-'24) a valuable "Sketch of the Botany of South Carolina and Georgia."

G. B. EMERSON, on "Trees and Shrubs of Massachusetts," 1846.

G. ENGELMANN wrote on *Cytinæ* in 1842, and with A. Gray on Lindheimer's Texan plants, 1845.

A *Florula Columbiensis* appeared at Washington in 1819, anonymously.

J. R. FORSTER, *Flora America Septentrionalis*, 1771 (also in Bossu's travels, vol. vill.).

A. GRAY, an eminent botanist of the United States; elementary books, monographs of American *Rhynchosporæ*, a revision of *Melantheæ*, remarks on *Ceratophyllaceæ*; has catalogued American *Gramina* and *Cyperaceæ*; reviewed J. Dumas, J. B. Boussingault, Johnston, and Draper, on the Chemistry of Vegetation; notes on the mountains of North Carolina; notices on Rafinesque, and on European herbaria; *Chloris Boreali-Americana*, illustrating rare plants; also a complete "Manual of the Botany of the Northern United States," 5th ed., 1868; "Introduction to Structural and Systematic Botany and Vegetable Physiology," 1858; "Field, Forest, and Garden Botany," 1869; began in 1849 his great work, *Genera Floræ Americæ Borealis illustrata*, which is to be in 10 vols. Many of his short works have been published in American

- literary periodicals. He was associated with G. Engelmann in a work on Lindheimer's plants of Texas; with W. S. Sullivan, who wrote on the mosses and liverworts of the United States east of the Mississippi; with J. Torrey, in the "Flora of North America," an abridged description of indigenous and naturalized plants north of Mexico, 2 vols., 1838-43.
- JO. FR. GRONOVIVS published *Flora Virginica*, Leyden, 1739-43; 2d ed., 1762, by his son, augmented with the observations of Clayton, Colden, Mitchell, Kalm, &c.
- W. JACKSON HOOKER, one of the best European botanists, published lists of plants on the E. coast of Greenland, 1823; an account of a collection of Arctic plants by Edw. Sabine, 1824; with Walker-Arnott, the botany of Capt. Beechey's voyage to the Pacific and Behring strait, 1841; a *Flora Borcault-Americana*, 2 vols. 4to, 1829-40, 233 plates (including Texas). His agents were Douglas, Drummond, Richardson, and others.
- ANDRÉ MICHAUX, *Histoire des chênes de l'Amérique*, published by his son François André, Paris, 1801, with 80 plates by the renowned P. J. Redouté. The son published, moreover, *Voyage à l'ouest des monts Alleghany et retour à Charleston par les hautes Carolines*, &c., Paris, 1804; *Mémoires sur la naturalisation des arbres forestiers de l'Amérique Septentrionale*, &c., 1806; *Notices sur les arbres Bermudes*, 1806; *Histoire des arbres forestiers de l'Amérique Septentrionale* (discussing their uses in arts, commerce, &c.), 3 vols. 4to, with 145 plates, 1810-18; and in connection with C. L. Richard, a *Flora Borcault-Americana*, containing the discoveries of his father, with 51 plates, 1808, republished with a mere change of title in 1820. An English epitome of the "Oaks," 1810-12, containing 26 black plates; and the imitation under the name of the "North American Sylva, or Forest Trees of the United States, Canada, and Nova Scotia," 150 colored engravings, 4 vols., Paris, 1817-18; 2d edition at New Harmony, Ind., 8 vols., 1840. An edition was printed at Paris for Philadelphia. (See Nuttall for the supplement.)
- H. MUELENBERG of Lancaster, Pa., catalogued the plants of that region, described *Gramina et plantas calumarias* of North America, 1817; his works were partly republished by his son.
- THOMAS NUTTALL published "Genera of North American Plants, and a Catalogue of Species," 2 vols., 1817-18; a description of new species and genera of composites, collected on a voyage across the continent, in Oregon, Upper California, and on the Hawaiian Isles, in 1834-5 ("Transact. Amer. Philos. Soc." 1841); and a supplement to F. A. Michaux's "North American Sylva," with additions of the trees observed in the Rocky mountains, Oregon, on the shores of the Pacific, &c., Philadelphia, 1742, with 122 colored plates; besides the works noticed elsewhere.
- FR. TRAUGOTT PURSCH (anglicized Pursh), *Flora America Septentrionalis*, 2 vols., London, 1814-16; a good work.
- DE LA PYLAIÉ, *Flore de l'île de Terre-neuve*, Paris, 1829.
- C. S. RAPINESQUE-SCHMALTZ published *Neogenyton* (describing 66 new genera of North American plants); a "Medical Flora of the United States," with more than 100 figures; the "Herbarium;" and the "New Flora and Botany of North America," supplemental to all American botanical works, as well as those of the great European botanists, &c.
- RICHARDSON, "Botanical Appendix to Sir J. Franklin's Narrative of a Journey on the Shores of Hudson's Bay and the Polar Sea."
- J. L. RIDDELL, "Synopsis of the Flora of the Western States," 1835.
- L. D. VON SCHWEINITZ, of Bethlehem, Pa., wrote, besides what is noticed elsewhere, a monograph of the American viola, and of the species of carices, and a synopsis of native fungi; a "Narrative of the Expedition to the Source of St. Peter's river, to Lake Winnepeck," &c., London, 1828, *Specimen Flora America Septentrionalis Cryptogamica*, Raleigh, 1821.
- J. L. E. W. SHEOUT, *Flora Carolinensis*, &c., collected or compiled, 2 vols., Charleston, 1806.
- C. W. SHORT, *Florula Lexingtoniensis*, 1880, a supplemental catalogue of the phanerogamous plants and ferns of Kentucky. He sent many plants and seeds to the Atlantic states and to Europe.
- W. S. SULLIVANT and L. LESQUEUX, several works on the mosses of North America, 1845-64.
- JOHN TORREY published, besides other works, a "Flora of the Northern and Middle States" (not beyond the *toosandria* of Linnaeus), 2 vols., 1824; a catalogue of the North American genera, according to Lindley's "Introduction," 1831; a monograph of the North American *Oyperaceae*; a "Flora of the State of New York, with a full Description of all indigenous and naturalized Plants, Remarks on Economy and Medicine," Albany, 1848-4 (in the 8d part of the "Natural History of New York," 1839), with 161 colored plates; *Icones inedite ad Floram Philadelphia illustrandam*, 180 colored plates. Some of Torrey's writings are found in the American scientific periodicals.
- EDWARD TRUCKERMAN arranged the carices, 1848, and gave a synopsis of the lichens of the Northern States and British America, 1848.
- S. WATSON and others, "Botany of the 40th Parallel Exploring Expedition," 4to, 1872.
- We add a list, in chronological order, of catalogues of the plants of various regions of America:
- JOHN BANISTER, in Virginia, 1680 (in *Raji Hist. Plantar., II. parte*, London, 1688).
- DAVID HOSACK, *Hort. Elginensis*, 1801-11.
- C. W. EDDY, *Plantae Plandomenses* (around J. L. Mitchell's country seat), 1807.
- J. LE COMTE, on the island of New York, 1811.
- H. MUELENBERG, *Catall. Plantar. Amer. Sept.*, 1813-18.
- J. TORREY, of plants within 80 miles of New York city, 1819.
- C. S. RAPINESQUE, of the botanical garden of the university of Transylvania, 1824.
- L. D. VON SCHWEINITZ, of plants collected in the Northwest territory (in the narrative of the expedition), London, 1825.
- J. TORREY, account of a collection of plants from the Rocky mountains, &c., 1827.
- E. HITCHCOCK, of the vicinity of Amherst college, 1829, and of Massachusetts, 1835.
- H. H. EATON, a few specimens from near Troy, 1832.
- H. B. CROOM and LOOMIS, of the neighborhood of Newbern, N. C., 1838.
- J. BACHMAN, about Charleston, S. C., 1834.
- T. NUTTALL, collection toward a flora of Arkansas, 1834.
- M. A. CURTIS, about Wilmington, N. C., 1834.
- L. R. GIBBS, phanerogamous plants about Columbia, S. C., 1835.
- DR. AIXIN, about Baltimore, 1836.
- J. L. RIDDELL, supplementary catalogue of plants of Ohio, 1836.
- J. A. LAPHAM, near Milwaukee, 1838.
- W. S. SULLIVANT, about Columbus, O., 1840.
- DEWEY's report on plants of Massachusetts, 1840.
- S. T. OLNEY, Rhode Island plants, 1844.
- Botanical Society of Wilmington, Del., plants of New Castle co., 1844.
- S. F. BAIRD, contributions toward a catalogue of trees and shrubs of Cumberland co., Pa., 1845.
- A. W. CHAPMAN, a list of plants about Quincy, Fla., 1845.
- F. B. HUGH, plants in Lewis co., N. Y., 1845.
- H. P. SARTWELL, of Western New York, 1845.
- HORACE MANN, phanerogamous and vascular cryptogamous plants of North America north of Mexico, 1865.
- The following writers, in addition to those already named, may be consulted by the student:
- ENGLISH.
- J. C. LONDON, author of 14 valuable works, from 1804 to 1841; and Mrs. J. W. LONDON, author of several popular ones, especially for ladies, 1840-57.
- SIR J. PAXTON, "Magazine of Botany," 8 vols., 1834-43, with 500 tables, and (assisted by J. Lindley) a pocket botanical dictionary, 1859.
- JOHN LINDLEY (besides the greater works mentioned above), "Outlines of the First Principles of Botany," 1830; "Key to Structural, Physiological, and Systematic Botany," 1835; "Ladies' Botany," 1837; "Introduction to Botany," 3d edition, 1839; "Elements of Botany," 1841.
- JOHN SMITH, "Domestic Botany," 12mo, London, 1871.
- FRENCH.
- BRISSEAU-MIRBEL, *Analyse des plantes*.
- DE CANDOLLE, *Théorie élémentaire de la botanique*, édit. 8, par Alphonse de Candolle, 1844.

BOTANY, a parish and township in the electoral district of Canterbury, Cumberland county, New South Wales, on Cook's river and on Botany bay, 5 m. S. of Sydney; pop. about 700. It is one of the most popular resorts of excursionists from Sydney on account of its beautiful scenery. It contains the Sydney water works, occupying an area of 30 acres, and weekly supplying that city with about 18,000,000 gallons of water. There are five places of worship, a temperance hall, and a post office. The principal industry is market gardening. It is an agricultural district, though the surrounding country consists of swamps and sand hills, with but occasional patches of fine alluvial soil.

BOTANY BAY, a harbor on the E. coast of Australia, county of Cumberland, New South Wales, 5 m. S. of Sydney, the N. head (Cape Banks) being in lat. 34° S., lon. 115° 16' E. The harbor is about 5 m. long from N. to S. and 6 m. wide from E. to W., but the entrance is little over 1 m. across. It receives the waters of Cook's and George's rivers, is capacious and open, but affords poor shelter for shipping. The S. shore of Botany bay is the spot first touched at, in April, 1770, by Capt. Cook, on his discovering the E. coast of Australia. Though the coast there is comparatively barren, Mr. (afterward Sir Joseph) Banks, botanist of the expedition, was so impressed with the profusion of the unknown local flora that the name of Botany was given to the bay. The reports of Capt. Cook led the English authorities to send out Capt. Arthur Philipps, the first colonial governor, in 1788, with about 1,000 persons, over 700 of whom were convicts; but neither the harbor nor its swampy surroundings were suitable for colonization, and he removed the men to Port Jackson. A brass plate on the cliffs marks Capt. Cook's first landing place; and a monument was erected there in 1828, by Bougainville and Ducampier, in honor of La Pérouse, who previous to his shipwreck was last heard from by the French government, through his letter dated Botany bay, Feb. 7, 1788.

BOTETOURT, a S. W. county of Virginia, intersected by James river; area, about 500 sq. m.; pop. in 1870, 11,329, of whom 3,163 were colored. It contains the sources of Craig's and Catawba creeks. Besides the Blue Ridge, which forms its S. E. boundary, there are other high ridges within its limits. The famous Peaks of Otter are near the dividing line between this and Bedford county; Middle-mountain is on the N. W. border. The James River canal has been opened from Richmond to

Buchanan. The chief productions in 1870 were 152,799 bushels of wheat, 95,986 of Indian corn, 92,307 of oats, 3,752 tons of hay, and 196,459 lbs. of tobacco. There were 2,044 horses, 1,984 milch cows, 3,426 other cattle, 3,332 sheep, and 6,192 swine. Capital, Fincastle.

BOTETOURT, Norborne Berkeley, baron, an English statesman, born about 1717, died at Williamsburg, Va., Oct. 15, 1770. He was summoned to parliament as Baron Botetourt (the peerage having been in abeyance since 1406), April 18, 1764. He arrived in Virginia in November, 1763, succeeding Sir Jeffrey Amherst as governor-in-chief of the colony. His first purpose was to enforce submission, and in 1769 he dissolved the assembly, which, however, convened in a private house. On becoming better acquainted with the colonists, he forwarded to England their remonstrances, with a favorable opinion against parliamentary taxation. A promise of repeal was held out to him by Lord Hillsborough, but finding himself deceived he demanded his recall, and died soon afterward of bilious fever aggravated by chagrin. He presented at his own expense gold and silver medals as prizes to the students of William and Mary college; and his statue was erected at that institution by the assembly in 1774. His title expired with him.

BOTH, two Dutch painters, brothers, natives of Utrecht. **I. Jan**, born about 1610, died about 1650. He was a pupil of Bloemaert, and lived in Italy, where he produced exquisite landscapes, representing perfectly Italian atmospheric effects. **II. Andreas**, drowned at Venice in 1650. He was also a pupil of Bloemaert, and, besides introducing figures into his brother's landscapes, painted after the manner of Bamboccio, but with finer coloring.

BOTHNIA, a gulf between Sweden and Russia, constituting the northern arm of the Baltic sea, extending from lat. 60° to 65° 50' N., 400 m. in length, with an average breadth of 120 m. At its mouth, about midway between the two shores, is the Åland archipelago, belonging to Russia, and the main entrance is the Ålands Haf, a strait about 24 m. wide, on the Swedish side of the islands. About midway of its extent it is gathered into a channel much narrower than its main body, called the straits of Quarken. The channel is also further intercepted at this place by several small islands, the principal of which is Holmö. The entire coast line of the gulf is very irregular. There is a strong current, or gulf stream, setting constantly from the head of the gulf southward, through Quarken, to Åland, where it divides into two, one passing E. and the other W., to reunite again, and also with a third current from the gulf of Finland, near the island of Kokar, whence it sets southward through the Baltic. There are good harbors, the principal of which on the Russian side are Abo, Björneborg, Uleåborg, and Tornea; and on the Swedish, Gefle, Hernösand, Pitea, Umea, and

Lulea. The S. shore of the gulf is annually visited by shipping for the export of timber and naval stores. It is usually completely frozen in the winter, so that armies have marched across it. The strong current and the abundant supply of fresh water, from a shed of an average breadth of 150 m. throughout its entire extent of coast line, give the waters of this gulf great freshness. The gulf of Bothnia presents an undoubted instance of slow upheaval of its E. and W. coasts, now taking place without volcanic action, at the approximate rate of two or three feet in a century. The coasts S. of Quarken are generally precipitous, and N. of the straits low and sandy. The numerous rivers which flow from Sweden and Finland into the gulf abound with fish, especially a kind of small herring called *strömming*, which constitutes a prominent article of food among the lower classes. A large part of the population on the W. coast are occupied in catching them. Most of these herrings are dried in the usual manner, but a considerable portion undergo fermentation in a closed cask, after having been previously a little salted and exposed to the air for a short time. The fish thus acquires a sour taste, and is called *surströmming*.

BOTHWELL, a village and parish of Lanarkshire, Scotland, on the N. shore of the Clyde, 8 m. E. S. E. of Glasgow; pop. of the village and parish about 18,000. The old Gothic church of Bothwell was used as a place of worship till 1828. A new parish church, with a tower 120 ft. high, was erected in 1833. The parish contains extensive iron works and collieries. It is famous in history for the battle fought on Bothwell bridge, about 1 m. from the village, June 22, 1679, between the Cov-

BOTHWELL, James Hepburn, fourth earl of, the third husband of Mary, queen of Scots, born about 1526, died at Malmö, on the coast of Sweden, in 1576. He occupied an influential position in the parliament of December, 1557. In 1558 he was made a lord of the articles, and shortly after lieutenant of the borders. In 1559 he intercepted Cockburn, master of Ormeston, near Haddington, as he was carrying £3,000 from England to aid the Scotch reformers. A little later, when the reformers showed signs of yielding before the regent's troops, he declared the earl of Arran, one of their leaders, a traitor to the government. In 1560, however, when Protestantism was made the established religion of the country, Bothwell declared himself of that faith, and was one of the Protestant nobles sent to France to offer their escort and service to Mary, queen of Scots, whose husband, the dauphin, had just died. Mary returned to Scotland in August of this year (1561), and at once formed a government under the leadership of her illegitimate brother, Lord James Stewart, Bothwell becoming a member of the privy council. But his quarrels and excesses made him intolerable in this position, and at the end of the year he was for a short time banished from Edinburgh. He now effected a reconciliation with the earl of Arran, and the two entered into a conspiracy to seize the queen at Falkland, on a journey into the earldom of Murray. Arran, who was already showing symptoms of insanity, changed his mood and confessed the plot. Both conspirators were imprisoned in Edinburgh castle; but Bothwell escaped, and was on his way to France when he was driven back by a storm and arrested at Berwick. Here he was kept three months, and then carried to London and imprisoned in the tower. The English government detained him there, without trial, for nine months; but the queen of Scots requested his release, although her ministers opposed his return to Scotland; and he was finally allowed to pursue his journey to France. In that country he was well received, and made captain of the Scottish guard; and he remained there till 1565, a few months before the marriage of Mary with Darnley at Edinburgh. Lord James Stewart, who had now received the title of earl of Murray, having caused him to be indicted for high treason, he once more fled the country, and a decree of outlawry was passed against him. After a short period, of which we have no detailed account, he suddenly appeared again in Scotland, gained Mary's favor, and in October, 1565, was a member of the newly organized privy council and a commander in Mary's army against the Scottish nobles who had taken up arms to oppose her marriage with Darnley. In 1566 he married Lady Jane Gordon, daughter of the earl of Huntly, who had been lord chancellor of Scotland. In the matter of the murder of Rizzio, Bothwell was a warm partisan of the queen, and earnestly opposed the plot. After

Bothwell Castle.

enanters and the royal troops, in which the former were defeated with great loss. The ancient castle, once the stronghold of the Douglases, is on a summit surrounded by woods, and is one of the finest ruins in Scotland. The manse of Bothwell was the birthplace of Joanna Baillie, whose father was minister there.

its consummation he aided the flight of Mary and Darnley to Dunbar castle, then under his control. On the return of the royal pair to Edinburgh Mary compelled Bothwell's bitterest enemies, Murray and Argyle, to go through the form of reconciliation with him. Many matters of moment were intrusted to him. Among these was the task of quelling a disturbance at Liddesdale, where he was severely wounded. Mary, who was at Jedburgh when this occurred, on hearing of his danger rode to Hermitage Castle, where he was lying, making the journey of 20 miles and returning the same day—an exertion which threw her into a violent fever, during which Bothwell in his turn hastened to visit her, though he was obliged to be conveyed to Jedburgh. The nature of the relations between him and the queen from this time forward has been the subject of a violent historical controversy between the assailants and defenders of Mary; but the following summary is confined to facts which are not denied by either party. (See MARY STUART.) The belief that Bothwell aspired to the hand of Mary now began to gain ground. He was one of the foremost in urging her to consent to a divorce, and he was certainly a leader in the conspiracy for Darnley's murder. Prosecuted by Darnley's father, the earl of Lennox, he was acquitted after a shamelessly partial trial, and shortly afterward his lands and offices were confirmed to him by a statute alluding to the queen's appreciation of his "gret and manifold gude service" to her and the nation. The day after the closing of parliament a number of leading nobles met at Ainsley, and drew up the paper called "the Ainslie Bond," whereby they expressed their approval of Bothwell's acquittal, proposed his marriage with the queen, and agreed to aid him in attaining this object and to defend it when attained. On April 24, 1567, as Mary was on her return from Stirling, Bothwell with a large body of men met her near Linlithgow, at Almond bridge, and overpowering her party carried her away to his castle of Dunbar, whether with or without the queen's consent is a matter of dispute. Bothwell now succeeded in procuring a full divorce from his wife, and in May he brought the queen to Edinburgh, where the banns of his marriage with her were published. On May 12 Mary, after she had solemnly declared that she was influenced only by her own will, signed a full pardon of Bothwell and his allies for their abduction of herself. She also created Bothwell duke of Orkney, and on May 15 was married to him at Holyrood. This step aroused the popular indignation to the point of armed resistance. The hostilities which followed in June culminated in the surrender of Mary at Carberry hill, and Bothwell fled to Dunbar, whence, being deserted by his former allies, and ordered to leave the country within twelve days, he took refuge in the Orkney islands. Pursued for acts of piracy committed in expeditions which he undertook, he fled to Den-

mark, and after a short period of impunity was imprisoned in the castle of Malmô, then belonging to the Danish king. Here he spent the remaining years of his life.

BOTOCUDOS (Port. *botoque*, a barrel bung), the name given by the Portuguese to a tribe of Tupayas Indians of Brazil, from their custom of wearing flat disks of wood in slits cut in the ears and under lip. By the coast Indians they were called Aymborés or Aimorés. According to tradition, they were driven from the north, and took up their habitation W. of a mountain range since called after them Serra dos Aymborés, separating the present provinces of Espírito Santo and Bahia from that of Minas Geraes. They call themselves Engereckmung, the signification of which is unknown. In Espírito Santo and Bahia they are commonly called Bugres, derived by Tschudi from the French, but apparently without warrant. They rarely approached the seashore, but in their occasional descents they gained a terrible reputation among the coast tribes, who regarded

Botocudos.

them with horror and as irrational beings, unskilled in the arts of hut building and of decorating their persons with feathers and other gaudy trappings. So strong was their antipathy to water, that their intended victim might always find safety by plunging into a river. They are of medium height, broad-shouldered, large-bodied, and muscular, their legs and arms, nevertheless, appearing soft, thin, and effeminate. There is a great variety of features among them, but in general they have low foreheads and small, black, piercing eyes, the exterior angles of which are usually oblique as in the Mongolian race, but blue eyes are not infrequent; small noses, at times somewhat arched at the base, especially in the women, and with wide alæ; small mouths; the lips are usually thick, though some individuals have very thin lips. Their cheek bones are much less prominent than in their neighbors of the Tupi-Guarani family. The hair on the head is thin, and when not allowed to fall over the forehead is

shaved with a bamboo razor for about two inches from the edge all round. The beard, naturally deficient, is commonly plucked out. The skin is a whitish yellow; and it has been affirmed that the Botocudos are capable of blushing. The women have the abdomen very large, the breasts flaccid and pendent, and are frequently bow-legged. All the hard work falls to their lot; they are the slaves of their husbands, who treat them with the utmost cruelty, beating them unmercifully and even cutting them with knives. Children while young are often treated with tenderness, and yet it is not unusual for the mothers to sell them to planters, who in reality hold them as slaves; but these rarely reach maturity. As a race, the Botocudos are decidedly ugly, exceptions to this rule being rare even in the young women. It has been erroneously stated that the Aymborés painted their bodies as other Indians do. They were formerly in the habit of varnishing their skin with the yellowish sap of certain trees, which gave them the appearance of having jaundice; but the intention was not to beautify but to preserve their bodies from the attack of mosquitoes and other insects. Their weapons consist of a bow about six feet long, so strong that none but an Indian can use it, and arrows of great length, sometimes barbed, with a sharp-pointed bamboo head, hardened in the fire. Their mode of combat is by attacking at night and from ambush. According to current belief, they were cannibals, and it is certain that after battle they ate the bodies of the slain, and that these feasts were conducted with great ceremony. They are fond of amusement, and have nothing of the stolid gravity of the northern Indians. Among their articles of diet are the larvæ of certain insects, ants, alligators, lizards, the boa constrictor, monkeys, the ounce and other carnivora, tapirs, and ant-eaters. The Botocudos have been considerably reduced in number by European vices, and above all by the passion for strong drink, by disease, and by the war of extermination unceasingly waged against them by the whites. Of those still existing, some are domesticated and divided into several small bands, each of which has its separate headquarters, called *aldeamentos*, or villages; others have resisted all efforts to civilize them, and roam in freedom through the forest. All of them inhabit the region between the Rio Doce and Rio Pardo, and watered by these rivers and the Mucury and Belmonte. They all go naked, except civilized ones when they visit the *fazendas* or plantations; and these close up the slit in the lip with wax. The ear plug is often four inches in diameter, and that for the lip two inches; but the custom of wearing them appears to be going out, and is only persevered in by the adult females. Old women always lack the lower incisors, which have been dislodged by the pressure of the plug; in many cases even the alveolæ have totally disappeared, leaving the bone bare and as sharp as a knife. The

Botocudo language is entirely different from the various Tupi tongues, and has dialectic differences observable in each band. It is rich in reduplicated words, but possesses no gutturals or sibilants, and is generally spoken in a high key, very rapidly, and apparently indistinctly.

BOTOSHIAN, or *Botushian*, a city of Roumania, in Moldavia, on the Shiska, an affluent of the Pruth, 60 m. N. W. of Jassy; pop. in 1866, 28,117. It is irregularly built, and contains 1 Armenian and 14 Greek churches, 10 synagogues, and a hospital. It has a considerable trade, especially in cattle, and is the seat of the most important fair in Moldavia.

BOTS, the larvæ of a species of gadfly, *gasterophilus equi*. The females deposit their eggs on the sides and legs of horses, where a glutinous fluid attaches the eggs to the hair. The horse in licking himself breaks the eggs, and a small worm adheres to the tongue, and is conveyed with the food into the stomach. There it clings firmly to the cuticular portion of the stomach by means of a hook on either side of its mouth, feeding on the mucus during the winter, and passing out with the chyme at the end of spring, by which time it has attained a considerable size. The larva buries itself in

Bot Fly.

the ground, becomes a chrysalis, and in a few weeks is changed into a fly. The bots cannot, while they inhabit the stomach of the horse, give the animal any pain or cause any injury; for he enjoys the most perfect health while the cuticular part of his stomach is filled with them, and their presence is not suspected until they appear at the anus. They cannot be removed by medicine, because they are not in that part of the stomach to which medicine is usually conveyed; and if they were, their mouths are too deeply buried in the mucus for any medicine that can safely be administered to affect them; in due course of time they detach themselves and come away. When, after death, the coats of the stomach are found to be corroded and perforated, and when bots are found either in the perforations or already passed through them, other causes have destroyed the stomach. Horses are frequently injured, however, by the medicines which are ignorantly given to remove the bots. This will easily be understood, when it is stated that bots have lived for many days together in olive oil, and even in oil of turpentine, and that tobacco and nitrous and sulphuric acids do not immediately kill them.

BOTTA. **L. Carlo Giuseppe Guglielmo**, an Italian historian, born at San Giorgio del Canavese, Piedmont, Nov. 6, 1766, died in Paris, Aug. 10, 1837. He was educated as a physician at the university of Turin, and also studied literature, botany, and music. In 1792 he was imprisoned for an alleged political offence, and, though nothing could be proved against him, he was

subjected to a rigorous confinement for 17 months. After his release he went to France, and was employed as surgeon in the army. Toward the close of 1796 he was sent to the Venetian islands of the Adriatic, where he wrote a "Historical and Medical Description of the Island of Corfu." In 1798 he was appointed a member of the provisional government of Piedmont, which was soon overthrown by the Austro-Russian invasion. He returned to France, was restored to his rank in the army, after the battle of Marengo became a member of the council which, with six commissioners, was to reorganize and administer the government of Piedmont, and a few months later, when a new government was instituted, he was one of the three commissioners who formed the executive. After the annexation to France in 1802 he became a member of the council of general administration, and published his *Précis historique de la maison de Savoie et du Piémont*. In 1804 he was chosen to the legislative body, and for some years was a resident of Paris. The first edition of his *Storia della guerra dell' indipendenza degli Stati Uniti d'America* (4 vols. 8vo) appeared in Paris in 1809-'10, was immediately reprinted in Italy, without compensation for want of a copyright law, passed through several editions, and was translated into English by George Alexander Otis of Boston (2 vols., 1826; new eds., New Haven, 1834 and 1840, and Cooperstown, 1848). In 1808 he was chosen vice president of the legislative assembly, and reelected to the same office the following year. In 1816 he published an epic poem in 12 cantos, entitled *Il Camillo, o Vejo conquistata*. In 1817 he was made rector of the academy at Rouen, where he remained till 1822. There he wrote his second history, the *Storia d'Italia del 1789 al 1814*, but it was not till 1824 that he was able to publish it. This, too, was immediately republished in Italy. In 1825 he wrote in French a general history of Italy for a popular library (8 vols.). The assistance of friends enabled him to connect his history of Italy with the great work of Guicciardini. He thus completed in five years the 10 volumes of the history of Italy from 1532 to 1789 (*Storia d'Italia continuata da quella del Guicciardini sino al 1789*, Paris, 1832). This was the last of his works. In the latter part of his life he received from Charles Albert a pension at first of \$600, and afterward of \$800. **II. Paul Émile**, a French archaeologist, son of the preceding, born about 1800, died at Achères, near Poissy, April 18, 1870. He made in his youth a voyage round the world, and formed on the W. coast of America a collection of natural curiosities. He accompanied as physician the expedition of Mehemet Ali to Sennaar, 1830-'33, and made a rich zoological collection. He was then appointed French consul at Alexandria, and in 1837 made another journey, the results of which he published in the *Relation d'un voyage dans l'Yémen* (Paris, 1844). In 1843, being consular agent at

Mosul, he began the excavation of Assyrian antiquities from the mounds on the banks of the Tigris, and published in 1848 *Écriture cunéiforme assyrienne*. The French government commissioned several eminent men to assist him in the preparation of *Monuments de Ninive, découverts et décrits par P. É. Botta, mesurés et dessinés par E. Flandin* (5 vols., Paris, 1849-'50), which was translated into English ("Letters on Discoveries at Nineveh," London, 1850 et seq.). Many of the discovered monuments were transported to Paris, and placed in the Louvre. Botta laid the foundation for the more important labors of Layard. In 1846 he became consul at Jerusalem, and in 1857 at Tripoli, where he remained till 1868.

BOTTA. I. Vincenzo, an Italian scholar, born at Cavallè Maggiore, in Piedmont, Nov. 11, 1818. He was professor of philosophy in the royal and national colleges of Turin, and in 1849 became a member of the Sardinian parliament. With Dr. Paroli he prepared a valuable work on public education in Germany (*Pubblico insegnamento in Germania*), which was published at the expense of the Italian government. Two parts of it were written by M. Botta and the third part by Dr. Paroli. Subsequently he settled in the United States, where he was naturalized, and has been for several years professor of Italian in the university of New York. His writings include *La questione Americana* (1861), "Discourse on the Life of Count Cavour" (1862), and "Dante, as Philosopher, Patriot, and Statesman" (1865). **II. Anne Charlotte Lynch**, wife of the preceding, an American poetess, born at Bennington, Vt. Her father belonged to the association of United Irishmen, participated at the age of 16 years in the rebellion of 1798, was by reason of his youth offered pardon if he would swear allegiance to the British government, refused, was imprisoned for four years, and then, being banished for life, settled in the United States. Miss Lynch was educated in Albany. In 1841 she published in Providence the "Rhode Island Book," a selection of prose and verse from the writers of that state. She soon after removed to New York, where her house became a resort of persons connected with literature and the arts. A collection of her poems was published in 1849, illustrated by eminent artists. Her principal prose work is a "Handbook of Universal Literature" (New York, 1860; 3d ed., 1873). She was married to Prof. Botta in 1855.

BOTTARI, Giovanni Gaetano, an Italian prelate, born in Florence, Jan. 15, 1689, died in Rome, June 8, 1775. He was director of the grand-ducal press of Tuscany, professor of ecclesiastical history and controversy in the Sapienza, and subsequently keeper of the Vatican library. He was principal editor of the new edition of the *Vocabulario della Crusca* and of the celebrated Vatican Virgil (1741).

BOTTESINI, Antonio, an Italian composer and contrabassist, born at Crema, Dec. 24, 1823.

He was taught the double bass in Milan by Luigi Rossi, according to the method of Andreoli and Dragonetti, and studied composition under several distinguished masters. When scarcely 23, he was engaged as contrabassist for the Italian opera in Havana, and afterward became director of the company. During the five years of his stay in Havana he paid occasional visits to the United States, where he became famous as a virtuoso, his renown being confirmed by his success on his return to Europe in 1851. In 1853 he visited the United States with M. Jullien, and afterward accompanied Mme. Sontag to Mexico. Subsequently he became director of the orchestra at the Italian opera in Paris, where his opera *L'Assedio di Firenze* was performed in 1857. In 1863 he produced at Barcelona *Marion Delorme*, and in 1871 his *Ali Baba* was performed in London. In 1872 he directed the Italian opera in Cairo.

BÖTTGER, Adolf, a German poet, born in Leipsic, May 21, 1815, died there, Nov. 16, 1870. He studied at the university of Leipsic, and his father, the author of a German-English dictionary, instructed him in the English and other foreign languages. He translated Byron (1840), Pope (1842), Goldsmith's poems (1843), Milton's poetical works (1846), Ossian (1847), Shakespeare's "As You Like It," "Midsummer Night's Dream," and "Much Ado about Nothing" (1847), Racine's *Phèdre* and Ponsard's *Odyssée* (1853), and Longfellow's "Hiawatha" (1856). Among his principal poems are *Pausanias*, *Der Fall von Babylon*, *Habana*, and *Die Tochter des Kain*. One of his most idyllic productions is *Goethe's Jugendliebe*, a description of some of Goethe's love affairs. A complete edition of his original poetical, dramatic, and prose works has been published in Leipsic in 8 vols. (1864 *et seq.*).

BÖTTGER, Böttcher, or Böttger, Johann Friedrich, a Saxon alchemist, born at Schleiz, Feb. 4, 1682, died in Dresden, March 13, 1719. His pretended discovery of the philosopher's stone resulted in the invention of Saxon porcelain. After various vicissitudes he gave the elector Augustus an account of his discovery, which is preserved in the archives of Saxony. The elector not availing himself of his suggestions, they were put in application by Count Tschirnhausen, who established a manufactory at Meissen in 1705, employing Böttger, who succeeded in producing with the reddish brown clay which abounds in the vicinity of Meissen a porcelain of remarkable beauty and solidity. After Tschirnhausen's death Böttger became in 1710 director of a manufactory, but was arrested shortly before his death for having offered to sell the secret of his art. Engelhardt wrote his biography (Leipsic, 1837).

BOTTICELLI, Sandro, an Italian painter, born in Florence in 1437, died there in 1515. One of his earliest frescoes, "St. Augustine in Ecstasy," is in one of the churches of Florence. He decorated for Sixtus IV. a chapel in the Vatican, and painted numerous figures of the

popes and three large frescoes. Among his masterpieces are "The Birth of Christ," now in a private collection in London, and a crowned Madonna in the gallery at Florence. He engraved the first 19 prints for the famous edition of Dante's *Inferno* printed at Florence in 1481. His devotion to Savonarola subjected him to much persecution.

BÖTTIGER, I. Karl August, a German archaeologist, born at Reichenbach, June 8, 1760, died in Dresden, Nov. 17, 1835. He was a teacher, and through Herder's influence became director of the Weimar gymnasium, and was well acquainted with Wieland, Goethe, and Schiller. In 1832 he was admitted to the French academy, after having been made director of the royal academy of knights in Dresden. Among his chief works are: *Sabina, oder Morgenstunden einer reichen Römerinn* (2 vols., 2d ed., 1806), and *Griechische Vasengemälde* (1797-1800).

II. Karl Wilhelm, son and biographer of the preceding, born Aug. 15, 1790, died Nov. 26, 1862. He became eminent as a historian, and edited a posthumous work of his father, *Litterarische Zustände und Zeitgenossen* (2 vols., Leipsic, 1838). He contributed the history of Saxony to Heeren and Ukert's *Europäische Staatengeschichte*, and his *Allgemeine Geschichte für Schule und Haus* and *Deutsche Geschichte für Schule und Haus* passed through many editions. From 1821 till his death he was professor of history in Erlangen.

BÖTTIGER, Karl Vilhelm, a Swedish poet of German descent, born at Westerås, May 15, 1807. After extensive studies and travels, he became in 1845 professor of modern literature at Upsal. He has translated Tasso's *Gerusalemme* and Dante's *Divina Commedia* into Swedish, and written the biography of his father-in-law Tegnér, besides many religious and other poems, most of which are contained in his *Samlade Skrifter* (3 vols., Stockholm, 1856-58). A selection of the latter has been translated into German.

BOTTLE, a hollow vessel, now generally made of glass or earthen ware, with a narrow neck. In ancient times, especially among the nomadic races, bottles were made of the skins of animals. Such are mentioned by Homer as being in use by the Greeks, Romans, and Egyptians. Herodotus describes the manner in which they were made by the Egyptians. The first distinct

FIG. 1.—Skin Bottles.

notice of them in the Bible is in the book of Joshua, where it is said the inhabitants of Gibeon "took old sacks upon their asses, and wine bottles, old and rent, and bound up." According to Chardin, the Persians preserve

wine in skins prepared with pitch, which prevents the imparting of an unpleasant flavor to the wine. In Spain various skins, and especially that of the goat, are still used for containing wine. The hide is stripped from the animal as entire as possible, and the various natural openings having been sewed up, with the exception of that of one of the legs, which is retained as a nozzle, the vessel is ready, after a certain preliminary curing of the skin, for the reception of the wine. The peculiar taste of Amontillado sherry is supposed to be due to its being kept in leather. The only word rendered bottle in the New Testament is *ἀσκός*, a skin or leathern bottle (Matt. ix. 17). In the Old Testament, however, earthen bottles are mentioned, as well as those made of skins. In the book of Jeremiah occurs the passage, "Thus saith the Lord, Go and get a potter's earthen bottle," &c. (xix. 1). Metal, earthen, and glass bottles were used in ancient times by the Egyptians, Assyrians, Greeks, and Etruscans. The Jews probably obtained their knowledge of them from the Egyptians. Re-

Fig. 2.—Egyptian Bottles. 1 to 7, glass; 8 to 11, earthenware.

mains of Egyptian earthen and glass vessels, of various forms and sizes, have been found, and shown to have been made at a very early period. There is a collection of these articles in the British museum, and of elegant vases, which are assigned to a time as far back as that of Thothmes III., about 1450 B. C. Glass bottles made several centuries B. C. were found at Babylon by Mr. Layard.—The manufacture of glass bottles, on account of the nature of the material, is necessarily very simple, although for the production of fine work great skill is required. Glass while in a plastic state will not admit of much contact with machinery or tools without having its molecular constitution so affected as to increase its liability to fracture. Therefore the finest bottles are blown, as they were in the earliest times, without the use of a mould, and with the aid of as few tools as possible; the operation being performed by simply gathering a proper quantity of molten glass upon the end of a metallic blowpipe, and forming it into shape by holding it in various positions while expanding it by blowing through the tube, and occasionally applying pressure

with some tool of very simple form. Generally, however, bottles are made with the use of a mould in which the glass is blown, because in this way time and labor are saved. Fig. 8

Fig. 3.—Mould.

shows the construction of a mould which is frequently used, especially in making small bottles and vials. It requires an extra hand, usually a boy, to open and shut it. For ordinary quart and pint bottles a mould is used with hinges at the bottom, and is closed by means of a lever which is moved by the foot of the operator. When this form of mould is used three hands are usually employed to make a bottle: one, a boy or apprentice, to gather the molten glass on the end of the blowpipe, one to blow the bottle and shape it in the mould, and a third to finish the neck and mouth and correct any defects in form. One person can perform the work, but not with equal economy of labor. The operation may be briefly described as follows: Gathering the proper quantity of molten glass upon the end of the blowpipe, which is a straight iron tube about five feet long, the gatherer hands it to the blower, who rolls it rapidly into a convenient form on the surface of a smooth iron or stone table, called a marver, at the same time expanding it slightly

Fig. 4.—Marver.

with the breath, then blows it to a suitable size for the mould, the axis of which is vertical. He then closes the mould, applies his mouth to the blowpipe, and blows with sufficient force to make the glass fit the cavity, and to take the impressions of whatever designs may have been engraved upon it. The mould is then opened and the bottle removed by means of the blowpipe, to which it still adheres. A punt, as it is called, is then attached to the bottom, to hold

Fig. 5.

it during the finishing process. This punt is an iron rod, upon one end of which a small ball of red-hot glass has been gathered so that it will adhere to the bottle, and it is applied as in

fig. 5, the neck of the bottle being cut off by the application of a cold iron or a wet stick, accompanied by slight traction. The finisher takes it, and, seating himself on a bench, *a*, fig. 6, which has some resemblance to an arm chair without a back, finishes the neck and mouth.

FIG. 6.—Finishing Bench.

Generally a band of molten glass is wound around the neck, at the mouth, which is then held in a flame till it attains the proper degree of pliability, and the shaping is done with one or more of the tools *a*, *b*, *c*, fig. 7. The chief

FIG. 7.—Finishing Tools.

use of the arms to the bench is to allow a rotary motion to be given to the bottle, by which it is held in position and its form retained. After the mouth is finished the punty is removed, and the bottle is received on a wooden rod or in a holder and taken to the annealing furnace, where it is placed upon a pan, which, with several others attached together in the form of a chain, is drawn slowly through a long, horizontal oven. When the pan arrives at the opposite end of the oven, its load of bottles is removed and it is returned to the mouth of the oven to receive a new load.—A patent was obtained by Henry Rickets of Bristol, England, in 1822, for a machine for making bottles which was not unlike the moulds now in use, although more complex. It had a contrivance for forming the bottom by pressure from without, which is of no mechanical advantage, and only injures the texture of the glass. Other patents for slight alterations in moulds have been obtained, but their adoption causes but little change in the process of blowing, which, for reasons above stated, cannot receive much modification as long as glass is the material from which the bottle is made.—The various bottles used for different well known purposes are generally distinguished by peculiar shapes and sizes, as, for example, the English wine, beer, ale, and soda bottles, the French champagne, burgundy, and claret, and the Rhenish wine bottles. Port wine is occasionally put into very large bottles, called magnums, and acids in still larger, termed carboys. Demi-johns are large bottles covered with wicker-work. The largest glass bottle perhaps ever manufactured was one blown at Leith, Scotland; its dimensions were 40 by 42 inches.

BOTTLE TREE (*sterculia* [*Delabechea*] *rupestris*), an Australian tree of the family *sterculiaceae*. It has the calyx 5-cleft, usually colored; no petals; column of stamens with 15 or rarely 10 anthers; stigma peltate; carpels 5, distinct, with two or more ovules; narrow, digitate leaves; paniculate, axillary inflorescence; flowers unisexual or polygamous, the female flowers expanding first. The tree has a greatly expanded trunk, which is swollen to a disproportionate size. Where the ground is

Bottle Tree of Australia.

rocky this expansion is greatest just below the branches; but in favorable soils the foot of the tree is largest, forming a uniform cylindrical column, from whose summit the branches issue as from the neck of a bottle.

BOTTOMRY, in maritime law, a contract by which the owner of a ship, or the master as his agent, hypothecates or binds the ship as security for the repayment of money advanced for the use of the ship. The name is derived from bottom, that is, keel, a figure by which the vessel itself is designated. In form it is a bond, by which, in consideration of the money lent, the borrower undertakes to repay it if the ship accomplishes its voyage, and pledges the ship for the performance of the undertaking. If the ship should be lost, the debt would be lost, that is, so far as it depends upon the bottomry bond; and in consideration of this risk, a higher rate of interest may be agreed for than is allowed in other contracts. In case of partial damage to the ship, it is usually provided that the lender shall bear his proportion of it, which will be the proportion the amount lent bears to the whole value of the vessel. The lender is not entitled to possession of the vessel, not even when the debt becomes due (unless it should be so expressly stipulated in the bond), but may enforce payment of the debt by a decree of a court of admiralty for sale of the vessel. The master is not authorized to enter into this species of contract except in a case of necessity,

usually when the vessel is in some foreign port, and he has no other resources for obtaining the necessary supplies. It would impair the obligation of the bond if there were in fact means of getting such supplies without hypothecation of the vessel, and this was known to the lender. A bottomry bond is a pledge of the ship and freight; a *respondentia* bond is a pledge of the cargo; but both ship and cargo may be included in the same instrument. As respects the cargo there is not strictly a lien for the money lent, except in case of partial loss; but if the voyage is successfully performed, the obligation is merely personal, unless an express provision be inserted in the bond for a specific lien upon the goods.

BOTTIS, John Minor, an American politician, born in Dumfries, Prince William co., Va., Sept. 16, 1802, died in Culpeper co., Jan. 7, 1869. After practising law a few years in Richmond, he settled on a farm in Henrico county. In 1833 he was elected to the state legislature, and was several times reelected. In 1839 he was returned to the 27th congress, and there advocated most of the points of Mr. Clay's programme—a national bank, a protective tariff, and the distribution among the states of the proceeds of the public lands. Though long a warm and intimate friend of John Tyler, Mr. Bottis at once abandoned him on his secession from the whig party; and in the presidential election of 1844 he supported Mr. Clay. After serving two terms in congress, he was defeated in 1843, but was again elected in 1847. In 1852 he resumed the practice of law in Richmond. After the death of Mr. Clay, and the dissolution of the whig party, he became attached to the American party. He was opposed to the repeal of the Missouri compromise, and sympathized with those southern members of congress who resisted the passage of the Lecompton bill in 1858. In 1861 he endeavored to prevent the secession of Virginia, and throughout the civil war was inflexibly faithful to the Union. He was imprisoned for a few weeks in 1862, and his farm in Culpeper county, where he then resided, was several times devastated. After the war he published "The Great Rebellion, its Secret History," &c. (New York, 1866). He was one of the signers of the bail bond of Jefferson Davis (1867).

BOTZARIS. See BOZZARIS.

BOTZEN (Ital. *Bolzano*), a town of Tyrol, Austria, in the circle of Brixen, beautifully situated at the confluence of the Talfer and Eisack,

Botzen.

the latter of which empties into the Adige 2 m. below the town, and on the Brenner railway, 52 m. S. of Innsbruck; pop. in 1869, 9,357, chiefly Italians. It is surrounded by mountains and built in an Italian style, many streets being bordered with arcades. It is protected against inundations by a strong dike. In the parish church, a Gothic building of the 14th century, is a monument of the archduke Rainer. In the new cemetery on the E. side of the church is a fine monument by Schnorr. The wine of Terlau, produced in the vicinity, is celebrated, and the country abounds in other good wines and in excellent fruit. The principal articles of trade are silk, leather, and fruit, and there are four annual fairs, the situation of the town at the junction of the roads to Germany, Italy, and Switzerland producing great commercial activity. The weekly markets are especially interesting, owing to the variety of Tyrolese costumes.—The Roman citadel Pons Drusi probably occupied the site of Botzen.

BOUCHARDON, Edme, a French sculptor, born May 29, 1698, died in Paris, July 27, 1762. He was the son of an architect and sculptor, studied in Paris, obtained a prize in 1723, and spent ten years in Rome, where he executed busts of Clement XI. and other great personages. The king recalled him to Paris, where he successively became designer to the academy of fine arts, member of the academy, and professor. Among his principal works are a fountain in the rue de Grenelle, which still exists, and his bronze equestrian statue of Louis XV., which was destroyed in 1792. The museum of modern statuary in the Louvre contains a cabinet which bears his name, and his statues of Amor and of Christ. Caylus wrote his life (Paris, 1762), and Bardon, *Anecdotes sur la mort de Bouchardon* (1764).

BOUCHIER, François, a French painter, born in Paris, Sept. 29, 1703, died there, May 30, 1770. He painted with remarkable facility,

and the number of his pictures and drawings is said to have exceeded 10,000, while at the same time he practised engraving. By pandering to the licentious taste of his times, he became fashionable and popular, and was called the painter of graces. For a long time after the first revolution his works were unsalable; but of late years they have again been sought for, especially by English amateurs, the gallery of the marquis of Hertford containing the erotic cabinet executed for Mme. de Pompadour. His most remarkable portrait is that of Mme. de Pompadour, and his best mythological picture, "Diana's Bath," is now in the Louvre.

BOUCHER, Jonathan, an English clergyman, born in Cumberland, March 12, 1738, died at Epsom, April 27, 1804. He went to Virginia about 1754 as a private teacher, afterward took orders in England, and was a rector in Virginia and Maryland till 1775, when he returned to England, his anti-revolutionary sentiments having given umbrage to his American congregation. From 1784 till his death he was vicar of Epsom. He is the author of "A View of the Causes and Consequences of the American Revolution, in 18 Discourses," dedicated to Washington (8vo, 1797), and of a "Glossary of Archaic and Provincial Words," intended as a supplement to Johnson's dictionary (A, 1802; A to G, 1807; enlarged ed., 1832).

BOUCHER, Pierre, sieur de Boucherville, a Canadian pioneer, born in Perche, France, in 1622, died at Boucherville, Canada, April 20, 1717. He came to America with his father in 1635, and was for many years Huron interpreter, and then rendered good services in the war against the Iroquois, whom he repulsed frequently. He was deputed to France in 1661 to lay before the court the condition of the colony. This led to the publication of his little work entitled *Histoire véritable et naturelle des mœurs et des productions de la Nouvelle France* (Paris, 1668). He was ennobled for his services and made governor of Three Rivers in 1663, and received a grant of Boucherville, on which he settled in 1668. He was esteemed as a brave, pious, intelligent, and upright man, and, having reared a large family, is the ancestor of many of the best houses in Canada. "The Adieux of Grandfather Boucher," addressed in his last days to his children, is eminently characteristic of the man and the time.

BOUCHER DE CRÈVECŒUR DE PERTHES, Jacques, a French archæologist and author, born at Rethel, department of the Ardennes, Sept. 10, 1788, died in Amiens in August, 1868. He belonged to an old family, and through the influence of his father, author of several botanical works and director of customs at Abbeville, he was employed by Napoleon on various missions to foreign countries. By a royal decree of 1818 he was permitted to add the family name of his mother, De Perthes, who claimed descent from an uncle of Joan of Arc, to his own. He wrote several tragedies and a comedy, and published anonymously in the

interest of free trade *Opinion de M. Christophe, vigneron, sur les prohibitions et la liberté de commerce* (4 parts, 1831-'4). Subsequently he became president of the *société d'émulation* at Abbeville, made an extensive collection of Celtic and Roman antiquities, which he presented to the government, and acquired celebrity by his archæological discoveries and by his work *De la création* (5 vols., 1839-'41). In 1841 he observed in some sand containing mammalian remains at Menchecourt, near Abbeville, a flint rudely fashioned into a cutting instrument; and during the formation of the *Champ de Mars* in the same locality, many of the since celebrated iron hatchets were found. He published his first work on the subject in 1846, *De l'industrie primitive, ou les arts et leur origine*, claiming that these implements belonged to the age of the drift; and his *Antiquités celtiques et antédiluviennes* (1847) contains many illustrations of the implements, and refers to remains found in the peat, which appear to have been the ruins of lake dwellings. He also wrote *De l'homme antédiluvien et de ses œuvres* (1860), and *Des outils de pierre* (1866). His miscellaneous writings comprise a novel and a volume of poetry; an alphabetical dictionary of passions and sensations entitled *Homme et choses* (4 vols., 1851); *Les masques, biographies sans nom*, being a collection of ethical disquisitions (4 vols., 1861-'4); *Sous dix rois, souvenirs de 1791 à 1860* (8 vols., 1862-'7); *Des idées innées* (1867); and numerous books of travel.

BOUCHES-DU-RHÔNE, a S. E. department of France, in Provence, on the Mediterranean, comprising the delta of the Rhône, bounded N. by the Durance and W. by the Rhône; area, 1,971 sq. m.; pop. in 1872, 554,911. The Rhône divides within the province into two branches, forming a delta called the island of Camargue, which is partly occupied by marshes and lagoons. On the north of the lagoons is La Crau, a dreary plain, mostly of gravel, stretching to Arles; during the summer it is entirely arid and waste, though in winter it furnishes pasture for sheep and goats. These flocks are sent to the mountains about the beginning of the spring, and return in the autumn. The horses and cattle are few and of poor breed. The quantity of corn gathered in the department is insufficient, while the produce of wine leaves a large surplus for export. Silkworms are raised in large quantities; and olives are cultivated on a great scale, being partly exported as fruit, and partly converted into oil. There are manufactories of soap, hosiery, and silk, sugar refineries, and oil mills. The trade is mainly carried on through the port of Marseilles, the capital. The department is divided into the arrondissements of Marseilles, Aix, and Arles.

BOUCICAULT, Dion, a British dramatist and actor, born in Dublin, Dec. 26, 1822. His father was a French refugee and a merchant in that city. He was sent to England to be edu-

cated as a civil engineer, under the guidance of Dr. Lardner, but devoted himself to the stage, and produced in 1841 his popular comedy of "London Assurance," at Covent Garden theatre. After the success of this play, he rapidly produced upward of 100 pieces, either original or adapted from the French, including "Old Heads and Young Hearts," "Love and Money," "The Rich Heiress," "Love in a Maze," "The Corsican Brothers," "The Willow Copse," "Janet Pride," "The Phantom," and "Faust and Margaret." He excels in constructive power, knowledge of stage effect, and epigrammatic dialogue. In September, 1853, he visited the United States, and after delivering several lectures in New York, he resumed his profession, writing and playing "Jessie Brown," "The Octoroon," and "The Colleen Bawn." In 1860 he returned to London, and brought out at the Adelphi theatre "The Colleen Bawn," which proved successful. A French adaptation of this drama was performed in Paris in 1861 under the title of *Le Sae de Glenaston*. In 1865 he produced "Arrah na Pogue" with equal success. This drama was also translated for the French stage under the title of *Jean la Poste*. In the seven following years he brought forth the comedies and dramas "The Long Strike," "Hunted Down," "How She Loves Him," "Flying Scud," "The Rapparee," "Formosa," "After Dark," "Foul Play" (in collaboration with Charles Reade), "Lost at Sea," "Rip Van Winkle" (which Mr. Joseph Jefferson has rendered so popular), "Kerry, or Night and Morning," "Elfie," and "Babil and Bijou." In the summer of 1872 he entered into partnership with Lord Londesborough and became the manager of Covent Garden theatre; and in the autumn of that year he made, together with his wife (Agnes Robertson), a second professional visit to the United States.

BOUDINOT, Elias, an American patriot, born in Philadelphia, May 2, 1740, died in Burlington, N. J., Oct. 24, 1821. He was descended from a family of French Huguenots, studied law, commenced practice in New Jersey, was early a devoted advocate of the patriot cause, and in 1777 was appointed by congress commissary general of prisoners, and during the same year was elected a member of congress. In 1782 he became president of that body, and as such signed the treaty of peace. In 1789 he resumed the practice of the law, but in 1796 was appointed by Gen. Washington superintendent of the mint, which office he held till 1805, when he resigned all public employments and retired to Burlington. He became a trustee of Princeton college in 1805, and endowed it with a valuable cabinet of natural history. In 1812 he became a member of the American board of commissioners for foreign missions, and in 1816 was made the first president of the American Bible society. To these and other institutions he made munificent donations. He was the author of several works, including

"The Star of the West, or an Effort to discover the Lost Tribes of Israel," in which he seeks to show that the American aborigines are Hebrews.

BOUET-WILLAUMEZ, Louis Édouard, count de, a French naval officer, born near Toulon, April 24, 1808, died in Paris, Sept. 10, 1871. He left the naval school in 1829 with the grade of ensign, became lieutenant in 1835, served in South America and at the bombardment of Mogadore, and was employed in 1838 in surveying the W. coast of Africa. In 1844, having attained the rank of captain, he was appointed governor of Senegal, where he remained till 1847. During the Crimean war he served as rear admiral, after which he was maritime prefect successively of Cherbourg and Toulon, commanding the Mediterranean squadron, and was promoted to be vice admiral. In 1865 he was made senator; and in 1870 he commanded the French squadron in the Baltic. He published *Description nautique des côtes comprises entre le Sénégal et l'équateur* (1849); *Campagne aux côtes occidentales d'Afrique* (1850); *Batailles de terre et de mer* (1855); and *Tactique supplémentaire à l'usage d'une flotte cuirassée* (1865).

BOUFARIK, a town of Algeria, in the centre of the plain of Metidja, 16 m. S. by W. of Algiers; pop. in 1866, 5,267, about half Europeans. In 1832 Gen. d'Erion established here an intrenched camp in the midst of a malarious swamp, and the early colonists suffered much from fevers; but by means of draining, the district has been rendered one of the most healthy and fertile in Algeria, producing the mulberry tree, grain, fruit, cotton, and tobacco. The town carries on an extensive trade, and is the seat of a large fair. Being upon the direct route from Algiers to Blidah and Oran, it is an important military post.

BOUFFÉ, Marie, a French comedian, born in Paris, Sept. 4, 1800. He was a mechanic previous to going on the stage. For 40 years he was one of the first French comic actors, especially excelling in vaudevilles. In 1855 he was much admired at the Varieties theatre in Paris in the *Abbé Galant*, and in 1857 in *Jean le Toqué*. Since 1864, when he gave his farewell performance, he has only played once at the Gymnase theatre, in 1866, in *La fille de l'avare*.

BOUFLERS, Louis François, marquis, afterward duke de, a French soldier, known as the chevalier de Boufflers, born Jan. 10, 1644, died at Fontainebleau, Aug. 22, 1711. He distinguished himself during the retreat of the French army before Montecuculi in 1675, and was created marshal in 1693. In 1708 he successfully withstood a siege in Lille for three months. At Malplaquet (1709) he served as a volunteer under his junior, Marshal Villars. When the latter was wounded, Boufflers was constrained to retreat; but he succeeded in saving all the guns, and left only 30 prisoners in the hands of the enemy.

BOUFLERS, Stanislas, marquis de, first known as the abbé, then as the chevalier de Boufflers, born at Lunéville in 1737, died in Paris, Jan. 18, 1815. His mother, who died in 1787, was one of the celebrities of the court of Stanislas Leszczynski, at Lunéville. His wit and elegant manners and his poetical talents rendered him a favorite at the court of Louis XV. He was a member of the constituent assembly (1789), and afterward went to Berlin, where he received from the king a grant of lands in Prussian Poland, to establish a French colony; but the plan failed. He married Mme. de Sabran and returned to France in 1800, and in 1804 was admitted to the French academy. He was a fervent eulogist of Napoleon, and was ridiculed for his extravagant praise of Jerome Bonaparte. The best collection of his works is that of 1828, in 2 vols., including his excellent "Letters from Switzerland."

BOUFLERS-ROUVREL, Marie Charlotte Hippolyte, countess de, born in Paris in 1724, died about 1800. She was a daughter of the count de Camper-Saugeon, and married the count de Boufflers-Rouvrel, who died in 1764; after which she led a gay life at the court of the duchess of Orleans, and was the reputed mistress of the prince de Conti, over whose receptions she presided. After the prince's death she retired to Autenil with her daughter-in-law the countess Amélie de Boufflers, afterward the duchess de Lauzun, who was guillotined June 27, 1794, and she herself was imprisoned until after the fall of Robespierre. She was intimate with Rousseau, and in correspondence with him 16 years, and was the friend of Hume, Grimm, and other celebrities. Walpole, in his partiality for Mme. du Deffand, decried Mme. de Boufflers, though the latter was regarded as one of the most intelligent women of her day.

BOUGAINVILLE, Louis Antoine de, a French soldier and navigator, born Nov. 11, 1729, died Aug. 31, 1811. He entered the military service as aide-de-camp to Chevert, and at the age of 25 published a treatise on the integral calculus. In 1754 he went to London as secretary of the French embassy; in 1756 he served in Canada as aide-de-camp to Montcalm, after whose death he returned to France. In 1761 he displayed such courage in the campaign on the Rhine, that he received from the king two guns which he had taken from the enemy. Peace being concluded, he entered the navy, and undertook to establish a French colony in one of the Falkland islands. Compelled to relinquish this settlement on account of the objections of Spain, he sailed southward, passed through the straits of Magellan, and entered the South sea, which was still for the most part unexplored. He looked in vain for Davis's land, then steered through the Paumotu archipelago, where he discovered several yet unknown islands, arrived at Tahiti, April 6, 1768, gave the name of Navigators' islands to the Samoan archipelago, and touched the part of the cluster which received a few years later from Capt. Cook the

appellation of New Hebrides. He then reconnoitred the E. coast of Australia, doubled the Louisiade islands, passed the large Solomon's archipelago, which had not been visited since its discovery by Mendana, and put in at Port Praslin, New Ireland, where he repaired his ships. He then took his course westward, discovering on his passage some small islands, and passing the N. shore of New Guinea. Finally he reached Booro, one of the Moluccas, where he procured a fresh supply of provisions, and in March, 1769, reached St. Malo, after a cruise of over two years. In 1771-'2 he published his *Voyage autour du monde* (2 vols., Paris), a very interesting account of his adventures, with a graphic description of the countries he had visited; it was immediately translated into English, and in 1783 into German. Bougainville had scarcely completed this work when he planned a voyage to the north pole; he wrote a memoir on the subject, proposing two distinct routes, and submitted it to the royal society of London, of which he had been admitted a member. In 1778, when the French took part in the American war of independence, Bougainville was appointed to the command of a ship of the line, and distinguished himself in all the engagements between the fleets of France and England. In the conflict in which De Grasse was defeated by Admiral Rodney, April 12, 1782, the Auguste, the ship commanded by Bougainville, suffered most severely, but maintained its station in the line to the last extremity; when no hope of retrieving the fortune of the day was left, by a judicious and decisive movement he succeeded in rescuing eight sail of his own immediate division, which he conducted safely to St. Eustace. Returning to France, he resumed his project of a voyage in the arctic seas, but received no encouragement, and finally left the naval service in 1790. In 1795 he was elected to the French institute, and subsequently became a member of the board of longitudes. On the organization of the senate, he was made a member of that body by Napoleon, who also ennobled him.

BOUGHTON, George H., an American painter, born in Norfolk, England, in 1836. His family removed to the United States about 1839, and he passed his youth at Albany, N. Y. He early developed a taste for drawing both figures and landscapes, and in 1853, having painted a few pieces which found a ready sale, he went to London and passed several months in the study of his art. Upon returning to America he settled in New York, and soon became known as a clever and rising landscape painter. Two of his works produced at this time, "Winter Twilight" and the "Lake of the Dismal Swamp," are noticeable for neatness of execution combined with no little poetic sentiment. They indicated a transition period from landscape to *genre* painting; and to fit himself for the latter he visited Paris in 1859 and devoted two years to study. In 1861 he opened a studio in London,

where he has since mostly resided, contributing annually to the royal academy exhibitions. His works are of cabinet size, and represent generally *genre* subjects in connection with landscapes. Though partaking somewhat of the mannerisms of the French school, they are often original in conception, and in respect to composition and imaginative power entitle the painter to take high rank among contemporary artists. Among the most successful are several depicting French peasant life, such as "Passing into the Shade," "Coming from Church," "Cold Without," and "Morning Prayer." On American subjects he has painted "The Scarlet Letter," "Return of the Mayflower," and "Puritans going to Church." Among his later works are "Reading Clarissa Harlowe," "Colder than Snow," and "The Idyl of the Birds," the last named a composition in three parts, refined in execution and infused with a singular pathos. Mr. Boughton is most successful in his female figures, which are always interesting and sometimes strikingly beautiful in features and expression. Of late years he has habited them in the long, narrow dress of about 1810, but without the eccentric accessories belonging to the fashion of that time.

BOUGIAH (anc. *Saldæ*; Fr. *Bougie*; Arab. *Bujayah*), a town of Algeria, capital of the province of Kabylia (created in 1873), beautifully situated in a mountainous region, about 112 m. E. of Algiers, on the W. coast of the gulf of Bougiah, which extends from Cape Carbon to Cape Cavallo; pop. in 1866, 2,836. On the summit of the principal mountain is a French fort, on the site of a former place of pilgrimage, which had earned for the town the title of Little Mecca. There are several other forts, and the town contains churches, mosques, a school, a hospital, an asylum for children, and a number of barracks. The roadstead is the safest on the coast of Algeria, and there is an active trade in oil, grain, wine, oranges, honey, and especially in wax.—The ancient *Saldæ* was a Roman colony of Mauritania Sitifensis under Augustus, and it was afterward the seat of a bishop. In the 5th century it became the capital of Genserio, king of the Vandals, and in the 8th it fell under Arab domination. As the residence of a powerful caliph it became in the 10th century, under the name of Bujayah, the chief emporium of N. Africa, and retained this prosperity under the subsequent rule of Morocco and of Tunis. An active trade was carried on with Italian merchants, especially with the Genoese, who erected here many public buildings. In the 15th century piracy injured the character of the place; and Spanish domination early in the 16th century brought about a decline, which under Turkish rule in the 17th culminated in utter ruin, from which the town has only partially recovered since 1833, when the French gained possession of it. It is the chief seat of trade with E. Kabylia.

BOUGUER, Pierre, a French physicist, born at Le Croisic, Feb. 16, 1698, died Aug. 15, 1758.

After holding a professorship of hydrography at Havre, he succeeded Maupertuis as associate geometer of the academy of sciences, and was afterward made pensioned astronomer. He accompanied La Condamine and Godin on the great South American expedition to measure an arc of a meridian near the equator, and on his return he published *Théorie de la figure de la terre* (Paris, 1749). His other works are on optics, astronomy, and navigation. His principal claims to fame are his invention of the heliometer, and his foundation of the science of photometry, which is most fully expounded in his posthumous *Traité d'optique sur la gradation de la lumière*, edited by La Caille (Paris, 1760).

BOUGUEREAU, Guillaume Adolphe, a French painter, born at La Rochelle, Nov. 30, 1825. He studied in the Paris school of fine arts, and has been prominent since 1855 among the artists of the modern French school. He executed the mural paintings in the St. Louis chapel of the church of Ste. Clotilde, and in the church of St. Augustine. His "Triumph of Venus" (1856) has been popularized by many engravings and lithographic drawings. There are many of his pictures in the United States.

BOUILLE, François Claude Amour, marquis de, a French general, born Nov. 19, 1739, died in London, Nov. 14, 1800. He distinguished himself in the seven years' war, was appointed governor of Guadeloupe in 1768, and at the beginning of the American war of independence was governor general of the French Antilles. He not only preserved those islands against the English, but succeeded in taking several others from them. At the same time he displayed such magnanimity that on visiting England at the conclusion of peace he received there public tokens of admiration. In the first years of the revolution he was in command of the eastern military division of France, and ably contended with great difficulties arising from the rebellious disposition of the population and the mutinous spirit of the troops. When Louis XVI. projected his flight from France, he consulted Bouillé, who entered into the plan and made all the necessary preparations; but notwithstanding all the efforts of the general, the king was arrested at Varennes (June 21, 1791). Bouillé thereupon fled from France and went afterward to Russia, where Catharine II. promised him an army of 30,000 men to invade France; but the promise was never fulfilled, and Bouillé repaired to England, where he wrote his excellent *Mémoires sur la révolution française*, first printed in English at London in 1797, translated into German (Hamburg, 1798), and not published in French till 1801.

BOUILLET, Marie Nicolas, a French metaphysician and encyclopædist, born in Paris, May 5, 1798, died there, Dec. 28, 1864. He was for 20 years professor of metaphysics and ethics in various colleges, and became honorary councillor of the university in 1850, inspector of the academy of Paris in 1851, and permanent

inspector general of public instruction in 1861. He edited the philosophical works of Cicero and Seneca, and the works of Bacon (3 vols., 1834-'5), and prepared the first complete French translation of the *Enneads* of Plotinus (3 vols., 1857-'61), for which he received a prize of 3,000 francs from the French academy. He contributed to various cyclopædias, and was the chief editor of the *Dictionnaire classique de l'antiquité sacrée et profane* (2 vols., 1826), *Dictionnaire universel d'histoire et de géographie* (1 vol. large 8vo, 1842; 2d ed., 1871), and *Dictionnaire universel des sciences, des lettres et des arts* (8vo, 1854; 9th ed., 1870). The second of these works was modified in accordance with the requirements of the Roman congregation of the Index.

BOUILLIER, Francisque, a French philosopher, born in Lyons, July 12, 1813. He became professor and dean of the faculty, and in 1856 president of the academy of that city; and since 1867 he has been director of the superior normal school. He prepared French translations of some of the works of Kant and Fichte, and is the author of the *Histoire de la philosophie cartésienne* (2 vols., Paris, 1854; 2d ed., 1867).

BOUILLON, a town of Belgian Luxemburg, on the Semoy, 17 m. W. S. W. of Neufchâteau;

riage into the family of La Tour d'Auvergne, viscounts of Turenne. Bouillon was held by the French from 1676 to 1815. The title of prince of Bouillon was assumed in 1792 by Philip d'Auvergne, a captain in the British navy, and was borne by him until his death in 1816, when the contest between different claimants was set at rest by a decision (July 1) in favor of the French prince Charles Alain de Rohan-Guemené, whose posterity still bear the title. Bouillon has belonged to Belgium since 1831.

BOUILLON, Godfrey de, the hero of the first crusade, born in South Brabant about 1060, died in Jerusalem, July 18, 1100. He was the son of Eustace II. of Boulogne, brother-in-law to Edward the Confessor. In 1076 he succeeded his maternal uncle, Godfrey the Humpbacked, duke of Lower Lorraine, in a part of his possessions. He espoused the cause of the emperor Henry IV. in the memorable struggle with Pope Gregory VII., slew the rival emperor Rudolph of Swabia in the battle of Molsen (1080), and a few years later planted Henry's banner on the walls of Rome, which he was the first to scale. In reward for these services he became duke of Lower Lorraine. The idea, however, that he had committed sacrilege by violating the city of St. Peter sat

heavy on his soul. As soon as the crusade was proclaimed, he mortgaged his lands to the bishop of Liège, in order to procure funds for the enterprise, and set out in the spring of 1096, with his brothers Eustace and Baldwin, for the Holy Land, at the head of 70,000 foot and 10,000 horse, French, German, and Lorrainers. Godfrey, who belonged to both the French and German nations, and spoke both tongues with ease, soon became the virtual leader of the whole vast expedition. (See *CRUSADES*.) He was not tall, but his strength was prodigious. It is said that

with one blow of his sword he clove asunder a horseman from head to saddle, and with one back stroke would cut off an ox's or camel's head. When in Asia, having one day lost his way, he found one of his companions in a cavern engaged with a bear; he drew the beast's rage upon himself, and slew it, but the serious bites he received kept him long in his bed. Alexis Comnenus agreeing to provide the western army with supplies on condition that the crusaders would expel the Turks from his dominions, Godfrey conquered Nicæa and in 1098 Antioch, where his soldiers were short of provisions, the Greek

Bouillon.

pop. in 1866, 2,765. It has an ancient castle, and was formerly the capital of the lordship of Bouillon (which had been separated by partition from the county of Boulogne), a district in the Ardennes containing several large villages and about 20,000 inhabitants. This district was mortgaged by Godfrey the crusader, in 1095, to the bishop of Liège, whose successors held it till 1482, when it was taken by Guillaume de La Marck, prince of Sedan. Restored to the bishop by Charles V. in 1529, it was again taken in 1548 by Robert de La Marck, whose descendants were dukes of Bouillon, which title afterward passed by mar-

emperor having failed to keep his promise. They regained their courage on the supposed discovery of the lance which pierced the side of the Saviour on the cross; and after a siege of 38 days, Godfrey, with only 20,000 men remaining of his army, captured Jerusalem, July 15, 1099. He tried, but in vain, to restrain the excesses of his soldiers, and a fearful massacre ensued. Elected king, he refused to assume a royal crown on the spot where the Saviour had been crowned with thorns, and, accepting only the title of duke and administrator of the Holy Sepulchre, surrendered to the patriarch the kingdom of Jerusalem, while he watched over the defence of the city, which was threatened by a vast Egyptian army. Godfrey soon died, probably of care and anxiety, after having founded a monastery in the valley of Jehoshaphat. He was buried on Calvary, and was succeeded by his brother Baldwin I., who assumed the title of king of Jerusalem. Godfrey's exploits have been celebrated by Tasso.

BOUILLON. I. Henri de la Tour d'Auvergne, duke de, marshal of France, born Sept. 28, 1555, died March 25, 1623. During the first part of his life he was known as viscount of Turenne. He received a military training under the superintendence of his grandfather, the constable de Montmorency. While still young he was converted to Calvinism, and became an adherent of Henry of Navarre. After his accession to the throne of France, Henry conferred on him the hand and estates of Charlotte de la Marek, the heiress of the duchy of Bouillon, and thus he became a powerful prince and assumed the title of duke de Bouillon. On the evening of his marriage, bidding adieu to his bride for a few hours, he stormed the fortress of Stenay, which was held by the Lorrainers. This made Henry say that he would make marriages every day if he could be sure of such wedding presents. He afterward participated in the conspiracy of Biron, and fled to Geneva, where he remained till 1606. During the regency of Maria de' Medici, Bouillon sometimes sided with the queen, sometimes with her opponents; now supporting the Calvinists, then making peace with the court. Yet he found time to establish at Sedan a large library and a college. After the death of his first wife he married Elizabeth of Nassau, daughter of William, prince of Orange, by whom he had two sons, the younger of whom was the celebrated Turenne. **II. Frédéric Maurice de la Tour d'Auvergne**, duke de, a French soldier, son of the preceding, born at Sedan, Oct. 22, 1605, died at Pontoise, Aug. 9, 1652. He was brought up in the Calvinistic creed, and learned the profession of arms under his uncles, Maurice of Nassau and Frederick Henry. In 1635 he entered the service of France, but six years later, from aversion for Richelieu, he joined the Spaniards. At the battle of La Marfée, July 6, 1641, fighting on the side of the count de Soissons, he displayed extra-

ordinary ability, but the withdrawal of the Spanish allies rendered victory useless. He then made peace with the cardinal, and was appointed lieutenant general, but the next year was arrested as an accomplice in the conspiracy of Cinq-Mars. He probably would have been executed if his wife, who was in possession of Sedan, had not threatened to deliver it up to the Spaniards. After the death of Louis XIII. he went to Rome, was converted to Catholicism, and placed in command of the papal troops. In 1649 he returned to France, where he actively participated in the civil war against Mazarin.

BOUILLY, Jean Nicolas, a French dramatist and novelist, born about 1763, died in Paris, April 14, 1842. He wrote the texts of many operas, including *Le jeune Henri*, by Méhul, and *Les deux journées* of Cherubini. He was also the author of several comedies and dramas, and of collections of tales for young persons, which were translated into German.

BOULAINVILLIERS, Henri, count de, a French historian, born at Saint-Saire, Normandy, Oct. 11, 1658, died Jan. 23, 1722. He asserted that France as a nation was indebted for its power to the feudal system, which in his opinion was the "masterpiece of human genius." His *Histoire de l'ancien gouvernement de la France* (the Hague, 1727) set forth this theory, and he wrote many other works.

BOULDER, a N. county of Colorado, bounded W. by the Medicine Bow mountains; area, 600 sq. m.; pop. in 1870, 1,939. It is watered by affluents of the South fork of the Platte river. The chief productions in 1870 were 54,891 bushels of wheat, 21,060 of Indian corn, 71,183 of oats, 3,898 tons of hay, and 84,253 lbs. of butter. There were 877 horses, 1,847 milch cows, 3,219 other cattle, and 183 swine. Capital, Boulder City.

BOULDERS. See **BOWLERS.**

BOULÉ, Théodore, a French publisher, born Feb. 23, 1799. In 1833 he founded the *Estafette*, and owned this journal till 1858, when, after 18 suits against him for stealing articles from as many other journals, it was suppressed by the government. On Feb. 24, 1848, he published the *République*, announcing the establishment of a republic previous to the official proclamation to that effect. His establishment was sacked June 13, 1849, by the national guard, and in 1850 he was deprived of his license as publisher. His business became then the property of a joint-stock company, which up to 1852 had already attended to the printing of more than 200 journals. Among the daily and periodical journals with which Boulé was connected as printer or proprietor, or in other capacities, were the *Revue Britannique* (1836), *Patrie* (1843-'5), *Figaro* (1855), &c. He has amassed an immense fortune.

BOULLONGNE. I. Louis, a French painter, born in Picardy about 1609, died in Paris in June, 1674. He studied in Italy, and after settling in Paris about 1640, he became one of

the organizers of the academy of painting and sculpture, and was professor in that institution till his death. His principal works were executed for the cathedral of Notre Dame. **II. Bon**, son of the preceding, born in Paris in 1640 or 1649, died there, May 16, 1717. A pupil of his father, his early picture of St. John was placed by order of Colbert in the academy, and he studied in Rome as a pensioner of the king. His imitations of great masters were afterward often taken for originals. He became in 1677 a member and in 1678 professor of the Paris academy, and Louis XIV. employed him. One of his most famous paintings is the "Resurrection of Lazarus" in the church of the Carthusians. He also produced a number of etchings. **III. Louis de**, brother of the preceding, born in Paris in 1654, died there in November, 1733 or 1734. In his 18th year he obtained the great prize of the academy, and in 1675 he went to Rome as a royal pensioner. After his designs in imitation of Raphael the Gobelins prepared tapestry for the king's apart-

ments. In 1691 he was admitted to the academy, and in 1722 appointed designer of medals and devices for the academy of inscriptions, in 1723 rector of the academy of painting and sculpture, in 1725 its president, and about the same time first painter to the king, by whom he was ennobled. His paintings are highly esteemed. He also excelled as an engraver. **IV. Geneviève and Madeleine**, sisters of the preceding, respectively born in 1645 and 1646, died in 1708 and 1710. They studied under their father, and were both admitted at the same time to the academy of painting (1699), exhibiting on this occasion a joint production. They were good portrait painters.

BOULOGNE. **I. Boulogne-sur-Mer** (anc. *Gessoriacum*, subsequently *Bolonia*), a town of France, in the department of Pas-de-Calais, situated on the English channel, at the mouth of the Liane, 19 m. S. S. W. of Calais, and 180 m. N. by W. of Paris; pop. in 1866, 40,251, including nearly 7,000 English. The upper town, irregularly laid out, but well built, con-

Boulogne-sur-Mer.

tains two squares with fountains, and an old castle where Louis Napoleon was confined after landing here in 1840. Among other public buildings is a cathedral built in the modern Italian style between 1827 and 1867, on the site of the Gothic building which was destroyed during the revolution. The citadel was razed in 1690. The ramparts have been transformed into promenades, and E. of them are the grounds which were used as a military camp in 1854-'5, and on many previous occasions. The lower or new town, lying close to the harbor, and containing the chief commercial establishments, is better laid out and built than the old town. It has a fine bathing establishment opened in 1863, with a ball room and reading room, and contains also a famous museum, and a library with over 80,000 volumes. The harbor, though still deficient in depth, has been much improved, and consists of two large basins connected by a quay,

ships anchoring some distance off in from six to nine fathoms. A great deal of the prosperity of the town is due to its situation on one of the main routes between London and Paris, being less than six hours' journey from London via Folkestone and Dover, and about 4½ hours from Paris by the new railway through Amiens, opened in 1867. About 300 vessels belong to the town, a large proportion of them engaged in the Newfoundland cod fishery. The fishermen generally marry only among themselves, live in a separate part of the town, have a peculiar dress, and speak a distinct patois. Before going to sea they make votive offerings in the neighboring chapel of Jésus Flagellé. The foreign trade is chiefly in herring, mackerel, oysters, wine, brandy, coals, butter, and linen, wool, and silk goods. Over 3,000 vessels enter and leave the port annually, with an aggregate tonnage exceeding 500,000. The population has nearly doubled since 1815,

chiefly owing to the influx of English residents; and the town looks now more English than French. There are two British chapels and many English boarding schools. Le Sage and the English poets Churchill and Campbell died in Boulogne, and Sainte-Benve was born here.

—Under the Romans the place was the port most frequented by travellers crossing to Britain. During the middle ages it was possessed by various princely houses, until it fell to that of Burgundy. In 1477 it was united to the French crown by Louis XI. In 1544 it was taken by Henry VIII. of England, but restored to France in 1550 on payment of 2,000,000 francs. It has been at various times the starting point of naval expeditions against England, and it was the centre of the great armament prepared by Napoleon for the invasion of that country. **II. Boulogne-sur-Seine**, a village of France, in the department of the Seine and arrondissement of St. Denis, on the right bank of the Seine, opposite St. Cloud, about 1 m. W. of the S. W. extremity of Paris; pop. in 1866, 17,343. It is famous for its bleacheries. Between Boulogne and the Porte Maillot of Paris is the Bois de Boulogne, originally a royal hunting ground. In the 18th century it contained the monastery of Longchamps, and subsequently was a celebrated forest till 1852, when it was converted into one of the finest pleasure grounds of Europe, covering nearly 2,500 acres. Among the most renowned features of the park were the deer park; the *rond des cascades*; the lakes; the *butte Mortemart*, an artificial mound; the *mare d'Auteuil*, a natural pond; the immense artificial rock-work called *cascade de Longchamps*, with the race course; the *pré Catalan*, with its concerts; the villa Haussmann, on the site of the old abbey of Longchamps; the zoological garden of acclimation; and the restaurant *château de Madrid*, called after the famous palace demolished under Louis XVIII. During the Franco-German war the trees were cut down by order of the military authorities of Paris, and the pleasure grounds otherwise devastated.

BOULTER, Hugh, an English prelate, born in or near London, Jan. 4, 1671, died in London in September, 1742. After leaving Oxford he was successively chaplain to the archbishop of Canterbury, rector of St. Olave's, Southwark, archdeacon of Surrey, chaplain to George I., and tutor to Frederiek, prince of Wales. In 1719 he became bishop of Bristol and dean of Christ church, Oxford, and in 1724 archbishop of Armagh and primate of all Ireland. He expended £30,000 in augmenting the incomes of the poorer clergy, erected and endowed hospitals at Armagh and Drogheda for clergymen's widows, contributed to the establishment of charter schools, and during the famine of 1740 provided at his own expense two meals a day for 2,500 persons. For 19 years he filled the office of lord justice of Ireland. His "Letters to several Ministers of State in England relative to Transactions in Ireland from 1724 to

1738" (2 vols., Oxford, 1769-'70) are regarded as authority on that period.

BOULTON, Matthew, an English mechanician, born in Birmingham, Sept. 3, 1728, died near there, Aug. 17, 1809. He joined his father in the manufacture of hardware, and one of his first inventions was a new mode of inlaying steel. The death of his father gave him ample means to extend his business, and in 1762 he established the Soho manufactory near Birmingham, for which he in 1767 constructed a steam engine, on the original plan of Savery. In 1769 he entered into partnership with James Watt, and the Soho steam engine, gradually improved and simplified, became known all over Europe. It was first applied to coinage in 1783, from 80,000 to 40,000 milled coins being struck off in an hour. Boulton and Watt sent two complete mints to St. Petersburg, and for many years executed the entire copper coinage of England. Mr. Boulton expended £47,000 on the steam engine before Watt had so completely constructed it that its operation yielded profit. He also patented a method of raising water and other fluids by impulse.

BOU MAZA, an Arab chief, born in Algeria about 1820. He was a dervish, who in 1845 roused the population of the Dahra against the French, participating in many conflicts and co-operating with Abd-el-Kader in Morocco. On April 13, 1847, he was compelled to surrender to Saint-Arnaud and sent to Paris. A liberal pension was granted to him, and he was provided with handsome lodgings; but being caught in an attempt to leave Paris in the night of Feb. 23, 1848, he was removed to Ham and detained in the fortress till July, 1849, and in the city till 1852. He was sent to the theatre of war in the East in 1854, and commanded a corps of irregular troops, receiving in 1855 a colonelcy in the army.

BOURBAKI, Charles Denis Sauter, a French soldier, born in Paris, April 22, 1816. His father, of Greek origin, and an officer in the French army, lost his life in the Greek war of independence (1827). Bourbaki was educated at St. Cyr, became a sub-lieutenant in 1836, and brigadier general in 1854. He distinguished himself in the Crimean war at Alma and Inkerman, and on Sept. 8, 1855, during the storming of the Malakhoff. Subsequently he was on the staff of the governor general of Algeria, and in August, 1857, became general of division. In 1859 he increased his reputation at the battle of Solferino, and afterward held a command in Paris. In May, 1869, he commanded the second camp at Châlons, and in July became aide-de-camp of Napoleon III. After the outbreak of the Franco-German war, he was appointed in July, 1870, commander-in-chief *ad interim* of the guard in place of Bazaine, under whom he took an active part in the battles near Metz, Aug. 14, 16, and 18, and especially on Aug. 31 in the unavailing attempt to break through the German lines. He succeeded in escaping from Metz in the beginning

of October, and was reported to have been sent by Bazaine on a mission to the ex-empress Eugénie at Chiselhurst. The provisional authorities at Tours next placed him in command of the first army of the north at Lille; but while he was exerting himself to qualify the troops for active service, Gambetta remonstrated against his inactivity, and Bourbaki, after rebutting these charges, laid down his command. On Dec. 6, however, he was placed at the head of part of the remnants of the defeated army of the Loire, which he reorganized around Nevers, so as to make it consist of four corps and eventually of about 150,000 men. Disappointed by Garibaldi's force not joining him for the relief of Belfort and in other projected exploits, he succeeded, nevertheless, in driving the enemy from Dijon; but his adversary, Gen. Werder, concentrated his forces at Vesoul, attacked the French flank at Villesexel (Jan. 9, 1871), gained time to intrench himself in a strong position before Belfort, and repeatedly repelled Bourbaki's impetuous attacks (Jan. 15-17). Dreading at the same time German reinforcements under Manteuffel, the French general retired to Besançon in the hope of thence reaching Lyons; but, cut off by the Germans, he was obliged to retreat over the left bank of the river Doubs in the direction of Switzerland. In the mean while he received visionary instructions from Gambetta to resume aggressive operations with demoralized forces, worn out by forced marches over Alpine mountains and glaciers, and short of the necessities of life. Depressed by these circumstances and exasperated at Gambetta's taunting him with treason, Bourbaki shot himself in the head at Besançon, Jan. 27. Expressing his regret that the wound did not prove fatal, he transferred his command to Gen. Clinchant, who, after new disasters, led the remaining 80,000 of the original 150,000 men of Bourbaki's army into Switzerland. Bourbaki has since been appointed to a military command in Lyons.

BOURBON. I. A N. E. county of Kentucky, bounded E. by the South Licking river, which also intersects the N. E. part, and drained by Hinkston, Stoner's, and Stroad's creeks; area, about 400 sq. m.; pop. in 1870, 14,863, of whom 6,677 were colored. This county forms part of the region called the garden of Kentucky. The surface is gently undulating, and the soil, of fine limestone derivation, is remarkably rich. Lead ore is found in small quantities; sulphur and chalybeate springs are numerous. On Stoner's creek is a remarkable ancient earthwork. The Kentucky Central and the Paris and Maysville railroads traverse the county. The chief productions in 1870 were 71,717 bushels of wheat, 67,789 of rye, 1,229,515 of Indian corn, 114,762 of oats, 163,850 pounds of butter, 47,585 of wool, and 5,572 tons of hay. There were 5,214 horses, 5,119 mules and asses, 3,870 milch cows, 16,629 other cattle, 11,038 sheep, and 19,887 swine. The

manufacture of Bourbon whiskey, which takes its name from this county, is extensively carried on. Capital, Paris. II. A S. E. county of Kansas, bordering on Missouri, drained by the Little Osage and Marmaton rivers; area, 625 sq. m.; pop. in 1870, 15,076. The Missouri River, Fort Scott, and Gulf, and the Missouri, Kansas, and Texas railroads traverse it. The chief productions in 1870 were 145,179 bushels of wheat, 706,607 of Indian corn, 266,320 of oats, 81,527 of potatoes, 20,789 tons of hay, 12,103 of wool, 255,218 of butter, and 225,569 gallons of sorghum molasses. There were 5,423 horses, 5,299 milch cows, 10,055 other cattle, 4,802 sheep, and 6,867 swine. Capital, Bourbon.

BOURBON, an island. See RÉUNION.

BOURBON, a French ducal and royal family, different branches of which have reigned as kings over France, Spain, and Naples, and as sovereign dukes over Parma. I. **DUHAL FAMILY.** The fief of Bourbon, now called Bourbon-l'Archambault, was early in the 10th century in the possession of Adhémar or Aymar, a descendant of Childebrand, brother of Charles Martel, and in the 13th century in that of the house of Dampierre, which held it till 1272, when Beatrix, the heiress, married the sixth son of Louis IX., Robert, count of Clermont, who thus became the head of the family. The fief, then only a seignior, was erected into a dukedom by Charles IV. for Louis, son of Robert and Beatrix (1327). He left two sons: Pierre I., the elder, who continued the ducal dynasty, and Jacques I., count of La Marche, the ancestor of the royal line. The second duke, Pierre I., was killed in 1356 at Poitiers.—His son Louis II. (1337-1409) distinguished himself in the war against the English, and was appointed conjointly with Philip the Bold, duke of Burgundy, to superintend the education of the young king Charles VI., who had married his sister. He was the true founder of the greatness of his house. To the duchy of Bourbon and county of Clermont he added, through his two marriages or by purchase, the duchy of Auvergne, the county of Montpensier, the principality of Dombes, and several minor feudal estates; so that he became one of the most powerful vassals of the crown, his possessions extending from the Cher to the Rhône.—JEAN I. succeeded his father Louis II.; was taken prisoner at the battle of Agincourt (1415), and carried to England; paid his ransom three times without being released; and at last concluded a treaty by which he gave up to the English king the principal strongholds of his duchy, at the same time acknowledging Henry VI. as king of France; but his son declined to abide by these terms, and the duke died in 1434 in London, after 18 years' captivity.—CHARLES I., known until his father's death as count of Clermont, did good service for the French king against the English, and was one of the negotiators of the treaty of Arras between Charles VII. and the duke of Burgundy in 1435. He

subsequently engaged in the revolt known as *la praguerie*, but soon made his peace with the king, a daughter of whom his son, the count of Clermont, afterward married. He died in 1456.—JEAN II., son of Charles I., was a faithful servant to Charles VII., but became the controlling mind of the *ligue du bien public* against Louis XI. By the treaty of Conflans he obtained favorable terms, being successively appointed governor of Languedoc, knight of St. Michael, and grand constable of France.—On his death in 1487 the duchy reverted to his eldest brother, the archbishop of Lyons, who died the following year, when their younger brother, PIERRE II. of Beaujeu, got possession of it. He married Anne, daughter of Louis XI. On the death of that king, Anne governed under the name of her brother, Charles VIII. Her only child was a daughter, Susanne, who married her cousin, CHARLES of Montpensier, the last duke, popularly known as the constable de Bourbon. He belonged to a younger branch of the family, and by his marriage with the heiress of the elder became the richest prince in France, and was appointed grand constable by Francis I. Louisa of Savoy, mother of the king, fell in love with him, but he repelled her advances. By her hostility he was deprived of his pensions, amounting to 76,000 livres; and on his wife's death, as she had left no child, Louisa claimed the Bourbon estates as the nearest of kin, and a lawsuit was brought against him. A judgment being rendered in her favor, Bourbon entered into secret negotiations with Charles V. and Henry VIII. It was agreed that a kingdom should be created for the constable in S. E. France, and the remainder of the country given up to the other confederates. Francis I. was informed of the plot, and Bourbon fled in disguise and raised in Germany 6,000 soldiers, with whom he entered the service of the emperor. He contributed greatly to the victory of Pavia, where Francis I. was taken prisoner. However, he was not treated by the emperor with the regard which he anticipated; and being at the head of a body of German mercenaries, who for months had received no pay, he was obliged to lead them against Rome. He was shot (May 6, 1527) while scaling the wall, upon which the soldiers stormed the city, which for two months was given up to pillage and bloodshed. His remains were removed to Gaeta, where a monument was erected to his memory; while the French parliament ordered the threshold of his mansion in Paris to be painted yellow, to signify that he had died bearing arms against his native country. II. ROYAL DYNASTIES OF BOURBON. 1. *France*. The head of the younger branch of the Bourbons, which gave kings to France, was Jacques, count of La Marche, second son of Louis, first duke of Bourbon. The sixth descendant of Jacques, Antoine de Bourbon, duke of Vendôme, married Jeanne d'Albret, the heiress of Navarre, by whom he had a son, Henri, prince of Béarn, born in 1553, who succeeded his father in 1562, and

in 1589, on the death of Henry III., the last prince of the Valois family, was the heir apparent to the crown of France. Henry the Béarnais, as he was called by the Catholics, made his claims good by courage, energy, and perseverance. At last, in 1594, he was acknowledged king of France as Henry IV., and was assassinated in 1610 by Ravallac. Six of his descendants in the direct line occupied the throne after him: Louis XIII., 1610–1643; Louis XIV., 1643–1715; Louis XV., 1715–1774; Louis XVI., 1774–1793; Louis XVIII., 1814–1824; and Charles X., 1824–1830. The reign of Louis XIV. lasted 72 years. This prince's sons and grandsons, excepting Philip, who was excluded on account of his accession to the throne of Spain, died before him, and he was succeeded by his great-grandson, then a child. Their two successive reigns covered together nearly a century and a half. The disorders and corruption which prevailed during the latter part of that period prepared the French revolution, to which Louis XVI. fell a victim. For more than 20 years his brothers were exiles from France; they returned to their country under the protection of foreign armies. Hence the comparative unpopularity of Louis XVIII. and Charles X., which caused at last the overthrow of the latter in 1830. The present head of this elder branch, and pretender to the throne (1873), is the count de Chambord, formerly duke de Bordeaux (called by his adherents Henry V.), the posthumous son of the duke de Berry, second son of Charles X., who was assassinated in 1820. The younger branch, known as Bourbon-Orléans, traces its origin to Philip, duke of Orléans, the brother of Louis XIV. It ascended the throne in 1830 in the person of his fourth descendant, who was styled Louis Philippe I., king of the French. He reigned 18 years, and lost his crown in the revolution of February, 1848. His surviving sons are the dukes de Nemours, Aumale, Montpensier, and the prince de Joinville. The present aspirant to the throne as the head of this branch is their nephew *le comte de Paris*, the elder son of the last duke of Orléans, who was accidentally killed in 1842. 2. *Spain*. On the death of Charles II., the last prince of the Austrian house of Spain, the crown passed under his will to Philip, duke of Anjou, grandson of Louis XIV., who reigned as Philip V., 1700–1746. His successors were Ferdinand VI., 1746–1759; Charles III., 1759–1788; Charles IV., 1788–1808; Ferdinand VII., 1814–1833; and Isabella II., who lost her throne in 1868, and in 1870 renounced her claims in favor of her son Alfonso. 3. *Naples*. Don Carlos, the second son of Philip V. of Spain, obtained in 1734–'5 the crowns of Naples and Sicily, which he kept till 1759, when he ascended the throne of Spain as Charles III., transmitting his Italian crowns to his third son, Ferdinand IV., who on his restoration in 1815 styled himself Ferdinand I. of the Two Sicilies. He reigned 66 years, including the period of

the French invasion, and was succeeded by his son Francis I., 1825-1830, the father of Ferdinand II., who in 1859 was succeeded by his son Francis II., whose possessions were in the following year conquered by Victor Emanuel. His eldest son is Prince Louis, count of Trani, born in 1838. 4. *Parma*. The infante Don Carlos, before becoming king of Naples, had been for a time duke of Parma and Piacenza. In 1748, by the treaty of Aix-la-Chapelle, his younger brother Philip, son-in-law of Louis XV., was invested with the duchy of Parma, which he transmitted to his son Ferdinand, whose heir was Louis I. The last named in 1801 exchanged his duchy for Tuscany, which had been erected into a kingdom under the name of Etruria. His son Charles II. succeeded him in 1803, under the guardianship of his mother, Maria Louisa, daughter of Charles IV. of Spain. In 1807 the same princess, on the promise by Napoleon of another kingdom in Portugal, consented to a resignation for herself and son; but the promise was never fulfilled, and they had to be contented in 1815 with the hereditary duchy of Lucca. In 1847 Charles II. was again put in possession of the duchy of Parma by the death of the empress Maria Louisa, to whom it had been given by the congress of Vienna. In 1849 he abdicated in favor of his son Charles III., who had in 1847 married a French princess, Louise Marie Thérèse, daughter of the duke of Berry. On the assassination of Charles III. in 1854, his son Robert I. was proclaimed duke, under the regency of his mother, who died in 1864, after the annexation of Parma in 1859-'60 to the dominions of Victor Emanuel.—Among the houses derived from the royal Bourbon family of France, the most important are those of Condé and Conti.

BOURBON, Louis Henri, duke of, the great-grandson of the great Condé, born at Versailles in 1692, died at Chantilly, Jan. 27, 1740. After the death of Louis XIV. he was a member of the board of regency, and on the death of the regent, Philip of Orleans, he was appointed prime minister. He obtained large sums from the public treasury, was involved in the schemes of Law, and increased his fortune by various questionable transactions. He allowed his mistress, the marquise de Prie, to control political affairs, and incurred so much odium by imposing onerous taxes that Cardinal Fleury prevailed upon Louis XV. to exile him in 1726 to Chantilly.

BOURBON, Louis Henri Joseph, duke of, prince of Condé, grandson of the preceding, born Aug. 13, 1756, died Aug. 27, 1830. In his youth he fought a duel with the count d'Artois, afterward Charles X. In 1782, in the war between the English and French, he was wounded at the siege of Gibraltar. He was among the first to emigrate, served in the army of Condé, and on his return to France after the restoration recovered most of his hereditary fortune. His mistress, the baroness de Fenchères, as he had no offspring, induced him to settle his

fortune upon the young duke d'Aumale, son of Louis Philippe. On the outbreak of the revolution of 1830 he proposed to cancel his will, and to give all his fortune to Charles X.; but he was found strangled the next month, under circumstances which led to a legal investigation. No light was cast upon the matter, and it was judicially admitted that he had committed suicide. He was the last duke of Bourbon.

BOURBON-LANCY, a watering place of France, in the department of Saône-et-Loire, 20 m. N. W. of Charolles; pop. in 1866, 3,222. Its mineral springs, which are employed in nervous affections and rheumatism, were known to the Romans under the name of *Aquæ Nisineii*. A fine hospital was established here by the marquis d'Aligre.

BOURBON-L'ARCHAMBAULT, a town of France, in the department of Allier, 15 m. W. N. W. of Moulins; pop. in 1866, 3,466. It is celebrated for its mineral springs and baths, said to be of great efficacy in cases of paralysis, rheumatism, and gun-shot wounds. It contains vestiges of the ancient castle of the Bourbon family, and was the capital of Bourbonnais.

BOURBONNAIS, a former province of central France, between the rivers Loire and Cher, now included chiefly in the department of Allier. It belonged for centuries to the ducal house of Bourbon, and was confiscated in 1523 by Francis I., and united to the French crown in 1531. Its ancient inhabitants were the *Ædui* and the *Bituriges Cubi*.

BOURBONNE-LES-BAINS (anc. *Aqua Borconis*), a town of France, in the department of Haute-Marne, 21 m. E. N. E. of Langres; pop. in 1866, 4,053. It has hot mineral springs, which were resorted to by the Romans. The temperature varies from 120° to 150° F. The water is principally employed in cases of paralysis and rheumatism, spasms, and ill-reduced fractures. There is a military hospital here.

BOURBON-VEKDÉE. See *NAPOLÉON-VEKDÉE*.

BOURDALOUE, Louis, a French prelate and orator, born at Bourges, Aug. 20, 1632, died in Paris, May 13, 1704. At an early age he entered the society of Jesus, and became professor of rhetoric, philosophy, and moral theology in their college at Bourges, displaying remarkable capacity for oral instruction, as well as great energy of character. He first preached in provincial churches, and in 1669 was sent to Paris, where he became very popular. Louis XIV. on many occasions invited him to preach at Versailles. He reformed in a measure the somewhat theatrical pulpit oratory of his day, and restored it to greater simplicity, directness, and sincerity. For 20 years he continued a favorite preacher. Louis XIV. sent him to Languedoc to reconcile the Protestants to the repeal of the edict of Nantes. In the latter part of his life he chiefly devoted himself to charitable labors. His sermons, often published during his lifetime, and translated into many foreign languages, are remarkable for their

solid learning and eloquence. The most celebrated of them is the sermon on the Passion. The edition by Père Bretonneau, in 16 volumes, is generally considered the most complete and valuable. Prominent among more recent editions is that of Didot (8 vols. 8vo, 1840).

BOURDEILLES. See BRANTÔME.

BOURDIN, Maurice, an antipope, born in Limousin, France, died at Fumone, Papal States, in 1122. He was arch priest of the diocese of Toledo in 1095, afterward bishop of Coimbra, and in 1110 archbishop of Braga. Pope Paschal II. sent him as legate to Henry V. of Germany, but excommunicated him for having crowned the emperor without authority, and for other acts of insubordination. After the death of Paschal and the election of Gelasius II. (1118), the emperor set up Bourdin as an antipope under the name of Gregory VIII., and drove Gelasius from Rome. But the opposition of the clergy rendered his position untenable, and after the death of Gelasius (1119) Henry was reconciled with Calixtus II., the legitimate successor to the papal see. The fugitive antipope was brought back ignominiously to Rome and imprisoned for the rest of his life in the castle of Fumone.

BOURDON, Louis Pierre Marie, a French mathematician, born at Alençon, July 16, 1799, died in Paris, March 15, 1854. He was professor in the principal colleges of Paris, and finally inspector of studies and a member of the council of the university. His *Éléments d'arithmétique* and *Éléments d'algèbre* have passed through many editions; and the latter, adapted by Prof. Charles Davies (1834), has been extensively used in the United States. His *Trigonométrie rectiligne et sphérique* was published in 1854 as a text book according to the new system of instruction in France.

BOURDON, Sébastien, a French painter, born at Montpellier in 1616, died in Paris in 1671. He became acquainted with Claude Lorraine in Rome, where he was denounced as a Calvinist, and obliged to return to Paris. There he was one of the founders of the academy of painting and sculpture. Exiled to Stockholm during the troubles of the Fronde, he was employed by Queen Christina as her principal painter; but when she embraced Roman Catholicism he returned to France. Many of his works, remarkable for a brilliant and easy style, are in French galleries, especially in the Louvre, which possesses his masterpiece, the "Crucifixion of St. Peter." He also excelled as an engraver, his prints in aquafortis exceeding 100.

BOURG, or **Bourg-en-Bresse,** a town of France, capital of the department of Ain, on the Reysouse, 20 m. E. S. E. of Mâcon; pop. in 1866, 13,733. The streets are narrow, but there are fine public buildings. A lyceum was opened in 1856. Outside the walls is the church of Notre Dame de Bron, with celebrated monuments of its founder, Margaret of Austria, of her husband, Philibert of Savoy, and of her mother-in-law, Margaret of Bourbon; it has a sun dial

reconstructed by the astronomer Lalande, who was born here. Bourg was important under the Roman empire, and successively belonged to the kings of Burgundy, the emperors of Germany, and the dukes of Saxony, coming into the possession of France in 1601.

BOURG, Anne du, a French Protestant martyr, born at Riom in 1521, executed in Paris, Dec. 20, 1559. He took orders, but quitted the church for the bar, became a professor of law, embraced Calvinism, and after remonstrating with Henry II. in behalf of the reformers, was imprisoned in the Bastille and degraded as a heretic by the archbishop of Paris. After the death of Henry II., the elector Palatine applied to Francis II. for his release, proposing to give him a professorship at Heidelberg; but Minard, one of his judges and the especial friend of the cardinal de Lorraine, being assassinated during the trial, the so-called *ordonnance minarde* was passed sentencing him to death. He was hanged in the place de la Grève, and his body burned.

BOURGADE, François, a French priest and orientalist, born at Ganjou, department of Gers, July 7, 1806, died in 1866. He was ordained in 1832, and in 1838 went as a missionary to Algeria, and thence to Tunis, where he founded a hospital, a college, and schools for girls, and was appointed to serve the chapel and other institutions for females established by Louis Philippe in honor of St. Louis (Louis IX.), on the spot where that monarch was believed to have died. He published *Soirées de Carthage*; *La clef du Coran*; *Le passage du Coran à l'Évangile*; *La toison d'or de la langue phénicienne*, containing many Punic inscriptions; part of a translation of the romance of Antares (1864); and a *Lettre à M. E. Renan* (1864), in reply to Renan's *Vie de Jésus*.

BOURGLAT, Claude, a French veterinary surgeon, born in Lyons in 1712, died in 1799. He began to practise as an advocate, and afterward served in the cavalry, where he became very skilful in the treatment of horses. In 1762 he opened a veterinary school at Lyons, the first in France. He was a member of the Paris and Berlin academies of science. The best of his many works, *Traité de la conformation extérieure du cheval, de sa beauté et de ses défauts* (Paris, 1776; 3d part by Huzard, 1803-'8), passed through many editions, and was translated into several languages.

BOURGEOIS, Anicet. See ANICET-BOURGEOIS.

BOURGEOIS, Dominique François, a French inventor, born in 1698, died in Paris in 1781. He first exhibited his mechanical talent while employed in a locksmith's shop in Paris. Having claimed the invention of the celebrated automaton duck of Vaucanson, he was indicted as an impostor and imprisoned over two years. In 1744 he invented a lantern which received the approval of the academy of sciences, and established a manufactory in which he was ruined by his partners. The academy having in 1766 granted him a prize for the best mode of light-

ing a town, the city of Paris gave him a monopoly for 20 years; but he was again defrauded by his associates, and died destitute. Catharine II. of Russia employed him in the construction of a lighthouse at St. Petersburg. Père Joly published under the name of Bourgeois two *Mémoires sur les lanternes à réverbère* (Paris, 1764).

BOURGES, a town of France, capital of the department of Cher, and formerly of the province of Berry, at the confluence of the Auron and Yèvre, 60 m. S. S. E. of Orleans; pop. in 1866, 30,119. Most of the old ramparts have been converted into promenades. The town has numerous interesting old houses and public

Cathedral of St. Étienne.

buildings. The cathedral of St. Étienne is one of the most celebrated in France, and in the church of St. Pierre is the tomb of Jeanne la Bienheureuse, consort of Louis XII. The hôtel de ville, originally the private mansion of Jacques Cœur, is an interesting building. The university of Bourges, founded in 1463, acquired great celebrity by the teachings of Alciatus, Oujas, Calvin, and Theodore Beza. It has since been converted into a lyceum. Charles VII., from his temporary residence here, was called king of Bourges. Bourges is the see of an archbishop, and has excellent institutions of education and art. It is renowned for its school of artillery and extensive military workshops, and is one of the great arsenals of France. It has an iron foundry, saltpetre works, and cloth manufactories. The chief

trade is in sheep, wool, cloth, hats, cutlery, hosiery, porcelain, wine, and confectionery. The town is remarkable for its jewellers' and silversmiths' shops. It is the birthplace of Bourdaloue. It occupies the site of Avaricum, the ancient and flourishing capital of the Bituriges Cubi, which was captured by Cæsar in 52 B. C., when almost all its defenders and inhabitants were slaughtered. It was subsequently the metropolis of Aquitania, under the name of Bituriges. Destroyed by Chilperic I., it was restored by Charlemagne and enlarged by Philip Augustus. During the middle ages many councils were held here. The pragmatic sanction of Bourges, established under Charles VII. in 1438, declared the pope subordinate to a general council.

BOURIGNON, Antoinette, a Flemish fanatic, born in Lille, Jan. 13, 1616, died at Franeker, Oct. 30, 1680. She was so ugly that at her birth it was proposed to kill her as a monster; nevertheless, being of a rich family, she received several offers of marriage, which she refused in order to devote herself to a religious life. In 1636 she fled from home in male disguise, to avoid marrying, and entered a convent at Cambray, where she pretended to inspiration and made a number of converts among the nuns. Attempting to escape with some of her disciples, she was expelled, and after the death of her father took charge of a hospital at Lille, whence she was also expelled. She then travelled extensively, and at Amsterdam abjured Roman Catholicism, and urged reforms in religion and politics. Thence she fled to Holstein to avoid arrest, and took up her residence in the island of Nordstrand, where she gave umbrage to the authorities by the clandestine publication of her mystical writings. She afterward wandered over various parts of Europe, claiming to be the medium of a new revelation supplementary to that of the Scriptures, making proselytes, but often persecuted as a witch. Shortly before her death she was at the head of a hospital in East Friesland. Lacoste, Peter Poiret, and Noels, the secretary of Jansen, were among her disciples. Her writings were published by Poiret (25 vols., Amsterdam, 1676-'84; new ed., 1717).

BOURMONT, Louis Auguste Victor de Chalsne, count de, a French soldier, born at the château de Bourmont, Maine-et-Loire, Sept. 2, 1773, died there, Oct. 27, 1846. At the beginning of the revolution he emigrated with his father, who was on the staff of the prince de Condé, and after fighting for the Bourbons in La Vendée, he offered his services to Bonaparte. Implicated in the plot of the infernal machine, he was arrested, but escaped to Portugal, and Junot's influence reinstated him in the favor of Napoleon, who, after his distinguished military services in 1813-'14, especially at the defence of Nogent, made him general of division. Alternately serving Louis XVIII. and Napoleon, he deserted the emperor on the eve of the battle of Ligny, and proceeded directly to

the Prussian headquarters. Joining Louis XVIII. at Ghent, he restored the Bourbon authority in many important towns, and saved several provinces from foreign occupation, in consequence of which he was promoted to the command of a division of the royal guard. In 1823 he commanded under the duke of Angoulême in the Spanish campaign, and at its end was raised to the peerage. In 1829 he became minister of war, and in 1830 commander-in-chief of the expedition to Algeria, during which he was made marshal; but after the accession of Louis Philippe, to whom he refused allegiance, he was superseded by Gen. Clausel and dismissed the service. He cooperated with the duchess of Berry in her attempt to raise an insurrection in La Vendée, served Dom Miguel in Portugal, and went to Rome in the interest of Don Carlos. The amnesty of 1840 permitted his return to France, but he was mobbed at Marseilles, one of his sons being wounded, and his wife dying three months afterward from the effect of the excitement. His testimony against Marshal Ney was regarded as having sealed that soldier's doom.

BOURNE, Hugh, an English clergyman, the founder of the Primitive Methodists, born at Stoke-upon-Trent, April 3, 1772, died at Bemersley, Oct. 11, 1852. In 1807 some of the Wesleyan Methodists were desirous of reviving camp meetings, which the British conference declared "highly improper for England." Mr. Bourne and 20 of his friends, dissenting from this judgment, were expelled from the body, and the new sect, which was called into existence under his leadership, eventually included over 100,000 members, the first society having been founded by him in 1810. In 1844 Mr. Bourne visited the United States, where his preaching excited much attention.

BOURNE, Vincent, an English Latin poet, born about 1700, died Dec. 2, 1747. He was a graduate of Cambridge and usher at Westminster school, where Cowper was among his pupils. A collection of his Latin versions of old English ballads, with some original poems, was published under the title of *Poemata* in 1734, and was followed by several others. In 1808 appeared his posthumous "Poetical Works," with his letters (2 vols., London; new ed., Oxford, 1826). Cowper translated several of Bourne's original Latin poems.

BOURRIENNE, Louis Antoine Fauvelet de, private secretary of Napoleon I., born at Sens, July 9, 1769, died in Caen, Feb. 7, 1834. He was the schoolmate of Napoleon at the military institute of Brienne, and subsequently spent some time at Vienna, Leipsic, and Warsaw. After his return to Paris he renewed his intimacy with Napoleon, then a poor and friendless officer; but the decisive turn taken by the revolutionary movement after June 20, 1792, drove him back to Germany. In 1795 he again returned to Paris, and there again met Napoleon, who however at that time treated him coldly; but toward the end of 1796 he was

installed as his private secretary. After the 18th Brumaire Bourrienne received the title of councillor of state, was lodged at the Tuileries, and admitted to the first consul's family circle. In 1802 the army contractor Coulon, whose partner Bourrienne had secretly become, and for whom he had procured the lucrative business of supplying the whole cavalry equipment, failed with a deficit of 3,000,000 francs; the chief of the house disappeared, and Bourrienne was banished to Hamburg. He was afterward appointed to watch in that city over the strict execution of Napoleon's continental system. Accusations of speculation arising against him from the Hamburg senate, from which he had obtained 2,000,000 francs, and from the emperor Alexander, whose relative the duke of Mecklenburg he had also molested, Napoleon sent a commission to inquire into his conduct, and ordered him to refund 1,000,000 francs to the imperial treasury. Thus, a disgraced and ruined man, he lived at Paris until Napoleon's downfall in 1814, when this amount was restored to him by the French provisional government, and he was appointed postmaster general, but removed by Louis XVIII., who, however, at the first rumor of Napoleon's return from Elba, made him prefect of the Paris police, a post he held for eight days. As Napoleon, in his decree dated Lyons, March 13, had exempted him from the general amnesty, he followed Louis XVIII. to Ghent, was thence despatched to Hamburg, and created on his return to Paris state councillor, and subsequently minister of state. His pecuniary embarrassments forced him in 1828 to seek a refuge in Belgium, on an estate of the duchess of Brancas at Fontaine l'Évêque, not far from Charleroy. Here, with the assistance of M. de Villemairet and others, he prepared *Mémoires sur Napoléon, le directoire, le consulat, l'empire et la restauration* (10 vols. 8vo, 1829-'31; English translation, 4 vols., Edinburgh, 1831). This work, which throws much light upon Napoleon's career, led to a counter-publication entitled *Bourrienne et ses erreurs volontaires et involontaires* (2 vols., Paris, 1830). The loss of his fortune, said to have been caused by the revolution of 1830, drove him mad, and the last two years of his life were spent in an asylum, where he died from apoplexy.

BOURRIT, Marc Théodore, a Swiss artist and author, born in Geneva about 1739, died near that city about 1815. He early evinced artistic talent, and reproduced the beauties of Alpine scenery in remarkable descriptions and illustrations, while gaining a livelihood as a chorister. Victor Amadeus of Sardinia and Louis XVI. became his patrons, and the latter gave him a pension. At the instance of Buffon, who had presented him to the French monarch, he took up his residence in Paris. After repeated unsuccessful attempts to ascend Mont Blanc with De Saussure, he succeeded in reaching the summit in 1787. He was remarkable for generosity and courage, once at great risk saving Prince

Galitzin, then unknown to him, from drowning. His principal works are : *Description des Alpes pennines et rhétiennes* (2 vols., Geneva, 1781); new edition, comprising also *Nouvelle description des glaciers et glaciers de la Savoie, particulièrement de la vallée de Chamouny et du Mont Blanc* (3 vols., 1787); and *Description des cols et passages des Alpes* (2 vols., 1803).

BOURSAULT, Edme, a French author, born at Mussy-l'Évêque, Burgundy, in October, 1638, died at Montluçon, Sept. 15, 1701. He went to Paris in 1651, became after a few years a popular writer, and was appointed teacher of the dauphin in reward for his publication *De la véritable étude des souverains* (Paris, 1671); but he declined this office, as well as membership of the academy, on account of his ignorance of Latin. By his attacks upon high personages at court he lost a pension of 2,000 francs that had been given him by Louis XIV., and narrowly escaped the Bastille. He assailed Molière, who revenged himself by impaling him in his comedy *L'impromptu de Versailles*; attacked Boileau in *La satire des satires*, but subsequently was of service to him; and disparaged Racine's *Britannicus* in a preface to his novel of *Artémise et Polianthe*. His *Lettres de respect, d'obligation et d'amour* (*Lettres à Babet*) derive a romantic interest from the story of Babet, who died in a convent to which she had been consigned by her parents on account of her devotion to Boursault. His fame rests chiefly on his comedies, *Ésopé à la ville*, *Ésopé à la cour*, and *Le Mercure galant*, the last of which is still occasionally performed.

BOUSSINGAULT, Jean Baptiste Joseph Diendonné, a French chemist, born in Paris, Feb. 2, 1802. He was educated in the mining academy at Saint-Étienne, and afterward employed by an English company to direct the working of some mines in South America. During the revolution and the war of independence he joined Bolivar, and obtained the rank of colonel. He explored Venezuela, and all the regions between Cartagena and the mouths of the Orinoco, as well as Peru and Ecuador, making numerous observations in meteorology and collections in botany and mineralogy. He was the friend and correspondent of Alexander von Humboldt. On his return to France, he was appointed professor of chemistry and dean of the faculty of sciences at Lyons; and in 1839 he became a member of the institute and taught in the chair of Dumas at the Sorbonne. Among his best works is *Économie rurale* (2 vols., Paris, 1844; English translation by Law, London, 1845; new French ed., *Agronomie, chimie agricole et physiologie*, 8 vols., 1861-'4). The appreciation of manures according to the proportions of nitrogen which they contain is chiefly due to the researches of Boussingault; and in coöperation with Dumas he measured the exact proportions of the constituent elements of atmospheric air. He has made valuable observations on the peculiar properties and uses of

different kinds of vegetables in the feeding and the fattening of cattle, and discovered a very simple method of preparing oxygen by means of baryta. He is one of the chief writers for the *Annales de physique et de chimie*, and for the annals of the academy. He was elected to the constituent assembly in 1848.

BOUTERWEK, Friedrich, a German metaphysician and writer on æsthetics, born at Oker, near Goslar, April 15, 1766, died at Göttingen, Aug. 9, 1828. He began the study of law at the university of Göttingen, but soon neglected it to devote himself to literary pursuits, and wrote a number of poems and a romance, *Graf Donamar* (republished at Göttingen in 1800). In 1787 he went to Hanover and afterward to Berlin; but, discouraged at the cold reception of his works, he returned in 1789, and applied himself to philosophy and literary history. He became a supporter of Kant, and delivered a course of lectures on his doctrines. In 1797 he was appointed adjunct professor of philosophy at Göttingen, and in 1802 full professor. From a disciple of Kant he became an ardent follower of Jacobi, his *Lehrbuch der philosophischen Wissenschaften* (2 vols., Göttingen, 1818; 2d ed., 1820) and his *Religion der Vernunft* (Göttingen, 1824) supporting opinions exactly opposed to those of his *Ideen zu einer allgemeinen Apodiktik* (1799). His principal and most famous work was his *Geschichte der neuern Poesie und Beredsamkeit* (12 vols., Göttingen, 1801-'19). The section of this work relating to Spanish literature has acquired an especially wide reputation; it has been translated into Spanish, and into English (2 vols., London, 1828). He also published *Æsthetik* (1806; with large additions, Leipzig, 1824) and *Kleine Schriften* (1818).

BOUTEVILLE, François de Montmorency, seigneur de, sovereign count of Suxe, a French duellist, born in 1600, beheaded in Paris, June 27, 1627. In his youth he served against the Huguenots, and acquired notoriety as the most intrepid and skilful duellist of his day. For one of his duels, fought on Easter day, 1624, he, his adversary, and their seconds were condemned by the parliament of Paris to be hanged; but they escaped, and the scaffold was destroyed by their friends. In 1626 he killed a marquis de Thorigny, then wounded one of his intimate friends who reproached him because he had not chosen him as his second. For these two affairs he was obliged to fly to Brussels. The governing archduchess received him kindly, and interceded for his pardon with Louis XIII. The king refusing, Bouteville exclaimed, "As the king refuses to pardon me, I shall fight next in Paris." This he did, fighting a duel with the marquis de Beuvron, a relation and avenger of Thorigny. For this both were executed, in spite of the intercession of many powerful friends. Bouteville left a widow, who six months after his death gave birth to a son, who became celebrated as the marshal de Luxembourg.

BOUTWELL, George Sewall, an American statesman, born in Brookline, Mass. Jan. 28, 1818. He is the son of a farmer, and received a common school education, which he supplemented by a course of reading and self-instruction, continued far into manhood. In 1835 he became a merchant's clerk in Groton, Mass., and subsequently was made a partner in the business. At 18 years of age he began the study of law, which he pursued chiefly by night, and of which he acquired a considerable knowledge, although he never became a practitioner. In 1840 he entered political life as an advocate of the election of Van Buren to the presidency, and between 1842 and 1851 he was seven times elected as a democratic member from Groton of the Massachusetts house of representatives, where he developed ability as a debater, and was recognized as a leader of his party. In 1844, 1846, and 1848 he was the democratic candidate of his district for member of congress, but failed in each instance of an election; and in 1849 and 1850 he was nominated by the same party for governor of the commonwealth. In 1849-'50 he was state bank commissioner. In 1851, by a coalition of democrats and freesoilers, he was elected governor, and in the succeeding year was again returned for the same office. After the repeal of the Missouri compromise in 1854 he left the democratic party, and the next year helped organize the republican party, with which he has since acted. He was a delegate in 1860 to the republican convention at Chicago, which nominated Lincoln for the presidency, and a member of the peace conference which assembled in Washington in February, 1861. In 1862, at the invitation of President Lincoln, he organized the new department of internal revenue, and was its first commissioner till March 4, 1863, when he became a member of congress, and was twice reelected to that office. In 1868 he was one of the managers in the impeachment trial of President Johnson. He was secretary of the treasury from March, 1869, to March, 1873, when he was elected United States senator from Massachusetts. He has opposed any considerable diminution of national taxation, and advocated a large annual reduction of the public debt. In 1870 congress at his recommendation passed an act providing for the funding of the national debt, by the terms of which the secretary of the treasury was authorized to sell certain bonds under certain plainly expressed conditions, but not to increase the debt. He attempted to effect this object through the instrumentality of a "syndicate," but in funding the new loan expended more than one half of one per cent., which was alleged to be in defiance of the law. The committee of ways and means of the house of representatives subsequently absolved Mr. Boutwell from this charge. He has been an overseer of Harvard college, was for five years secretary of the Massachusetts state board of education, in which capacity he prepared elaborate

annual reports, and was a leading member of the Massachusetts constitutional convention of 1853. He is the author of "Educational Topics and Institutions," a "Manual of the United States Direct and Revenue Tax" (1863), and a volume of "Speeches and Papers" (1869).

BOUVART, Alexis, a Swiss astronomer, born near Mont Blanc, June 27, 1767, died June 7, 1843. He went to Paris in 1785, attended the free lectures at the collège de France, was attached to the observatory, in 1804 became a member of the bureau of longitudes, and was elected to the academy of sciences through the influence of Laplace, whom he assisted in the *Mécanique céleste*. In 1808 he published new tables of Jupiter and Saturn, to which in 1821 he added those of Uranus, whose perturbations he was the first to point out and explain. Leverrier's discovery of Neptune in 1846 confirmed Bouvart's hypothesis.

BOUVET, Joachim, a French Jesuit missionary, born at Le Mans about 1662, died in Peking, June 28, 1732. Sent by Louis XIV. to China, he was employed by the Chinese emperor in directing various public buildings, and allowed to build a church within the imperial city. On his return to France in 1697, he presented to Louis XIV. 49 Chinese works, and in 1699 departed again for China with 10 other missionaries. He labored for nearly 50 years to promote the progress of the sciences in that empire, gave an account of the state of China in several treatises and letters, and composed a Chinese dictionary, which has never been printed.

BOUVIER, John, an American jurist, born at Codognan, France, in 1787, died in Philadelphia, Nov. 18, 1851. He was of a Quaker family, which emigrated to this country and settled in Philadelphia when he was in his 15th year. He obtained employment for several years in a bookstore, published a newspaper for a short time at Brownsville, was admitted to the bar in 1818, and in 1822 began to practise in Philadelphia. In 1838 he became associate judge of the court of criminal sessions. He published in 1839 a "Law Dictionary, adapted to the Constitution and Laws of the United States of America, and of the several States of the American Union," the fruit of 10 years' labor (2 vols. 8vo). In 1841 he commenced a new edition of Bacon's "Abridgment of the Law," in 10 vols. royal 8vo. His greatest work, published two months before his death, was the "Institutes of American Law" (4 vols. 8vo).—His daughter and only child, HANNAH M. BOUVIER, born in 1811, is the author of a popular work entitled "Familiar Astronomy," illustrated by celestial maps and engravings, with a "Treatise on the Globes," &c. (8vo, Philadelphia, 1857).

BOVES, José Tomas, a Spanish American military adventurer, born in Spain, killed at Urica, Venezuela, Dec. 5, 1814. While employed as a naval officer on the northern coast of South America he was tried and imprisoned for brib-

ery and prevarication. After his release he acted with the revolutionists on the outbreak of the war of independence in Venezuela, but subsequently joined the royalists and served as captain under Oagigal, after whose defeat he took up an independent position at Calabozo, and with 500 men, many of whom were slaves, defeated Maríño, dictator of the eastern provinces. His band being increased by vagabonds and fugitives from justice, he worsted the independents twice, slaughtered all his prisoners, and gained for his force the name of the infernal division. He was defeated by Rivas, when many of his men were captured and put to death; but in 1814 he beat Bolívar and Maríño at La Puerta, and captured Valencia after a blockade, and, in violation of a solemn pledge, ordered the republican officers and many of the soldiers to be shot. Boves, coöperating with Morales, was again victorious at Angaita, obliged Bolívar to retreat to Cartagena, and entered Carácas. He fell in the battle of Urica, and was buried while his victorious troops were massacring their captives.

BOVINES, or *Bouvines*, a village of French Flanders, on the Marq, 7 m. S. E. of Lille, celebrated for the victory gained by Philip Augustus of France over Otho IV. of Germany, July 27, 1214. In 1340 Philip of Valois defeated here 10,000 English troops; and on May 17 and 18, 1794, the French here defeated the Austrians.

BOVINO (anc. *Bovinum* or *Vibinum*), a fortified town of Italy, in the province of Capitanata, 18 m. S. S. W. of Foggia; pop. about 6,000. It is memorable for a defeat of the imperialists by the Spaniards in 1794.

BOW. See **ARCHERY**.

BOWDICH, *Thomas Edward*, an English traveler, born in Bristol in 1790, died in Africa, Jan. 10, 1824. He went to Cape Coast Castle, where his uncle was governor, in 1816, as writer in the service of the English African company; and in 1817 he was second in command of a mission to Ashantee. Becoming chief of this mission, he concluded an advantageous treaty with the Ashantee ruler. He afterward went to Paris and studied under Cuvier and other eminent men, with a view of preparing himself for a second African expedition; but he succumbed to the climate soon after reaching the mouth of the Gambia. He published works on African travel and geography, the most important of which is "Mission from Cape Coast Castle to Ashantee" (London, 1819).

BOWDITCH, *Nathaniel*, an American mathematician, born in Salem, Mass., March 26, 1773, died in Boston, March 16, 1838. The son of a cooper, he was sent to school till 10 years of age, and was then taken into his father's shop. He was soon transferred to a ship chandlery, and remained in this business till he made his first voyage in 1795. His education and all his labors in mathematics were accomplished by improving his leisure while pursuing other avocations. An English sailor taught him the ele-

ments of navigation. He began the study of Latin alone, that he might read the *Principia* of Newton; and later in life he taught himself Spanish, Italian, and German. Between 1795 and 1803 he made five long voyages, successively as clerk, supercargo, and master, to the East Indies, Portugal, and the Mediterranean. On his return from his last voyage he arrived off Salem by night in a violent snow storm, and with no other guide than his reckoning, confirmed by a single glimpse of the light on Baker's island, found his way safely into the harbor. In 1802 he published his "New American Practical Navigator," which passed through many editions, and was esteemed the best work of the sort ever published (English ed. by Kirby, London, 1802). On the close of his seafaring life, he was elected president of the Essex fire and marine insurance company, which situation he held till 1823. His attachment to his native place made him decline the chair of mathematics in Harvard university in 1808, in the university of Virginia in 1818, and at West Point in 1820. Among his productions were a chart of remarkable beauty and exactness of the harbors of Salem, Marblehead, Beverly, and Manchester; many contributions, chiefly on astronomical subjects, to the "Transactions" of the American academy of arts and sciences; the article on modern astronomy in vol. xx. of the "North American Review;" and many articles in the American edition of "Rees's Cyclopædia." He completed between 1814 and 1817 the great undertaking on which his fame chiefly rests, a translation of the *Mécanique céleste* of Laplace (4 vols., 1829-'38); the 5th volume, which Laplace had added to his work many years after the other, was subsequently issued under the editorial care of Prof. B. Peirce, accompanied by an elaborate commentary. It was estimated that there were at that time but two or perhaps three persons in America, and not more than 12 in Great Britain, who were able to read the original work critically. The French astronomer, thoroughly master of the mighty subject, very often omitted intermediate steps in his demonstrations, and grasped the conclusion without showing the process. It was the design of Dr. Bowditch to supply these deficiencies. Another object was to record subsequent discoveries, to continue the original work to the latest date, and to subjoin parallel passages from geometers who had treated of the same subjects. A third object was to show the sources from which Laplace had derived assistance. The elucidations and commentaries form more than half the work as produced by Dr. Bowditch. In 1823 he became actuary of the Massachusetts hospital life insurance company in Boston. During the latter years of his life he was a trustee of the Boston Athenæum, president of the American academy of arts and sciences, and a member of the corporation of Harvard college.—See "Memoir of Nathaniel Bowditch," by his son, N. I. Bowditch (Boston, 1839).

BOWDOIN. **I. James**, governor of Massachusetts, born in Boston, Aug. 8, 1727, died Nov. 6, 1790. He was a descendant of Pierre Baudouin, a French Huguenot who fled to America on the revocation of the edict of Nantes. He graduated at Harvard college in 1745, became in 1758 representative in the general court, and was subsequently senator and councillor. During the troubles which preceded the revolution, he was forward in opposition to the royal governor. In 1775 he was president of the council of government; when the convention assembled in 1778, for the formation of a constitution, he was chosen president; and in 1785 he succeeded Hancock as governor. It was during his administration that the disturbances in the western counties of Massachusetts, known as Shays's rebellion, occurred. He called out 4,000 militia, and the speedy suppression of the insurrection was due to his vigorous course; yet he lost his election the next year. He was afterward a member of the convention for the adoption of the federal constitution. He was a friend and correspondent of Franklin, and one of the founders and first president of the academy of arts and sciences, to which he bequeathed his library. He left a legacy to Harvard college, and aided in the establishment of the Massachusetts humane society. **II. James**, son of the preceding, born Sept. 22, 1752, died on Naushon island, Mass., Oct. 11, 1811. He graduated at Harvard college in 1771, afterward spent one year at Oxford, and commenced his travels on the continent, but returned to the United States after the battle of Lexington. He was minister to Spain from 1805 to 1808, and acquired in Paris an extensive library, philosophical apparatus, and collection of paintings, all of which he left at his death to Bowdoin college, together with 6,000 acres of land, and the reversion of the island of Naushon, one of the Elizabeth islands in Buzzard's bay, which had been his favorite residence.

BOWDOIN COLLEGE, the oldest and most prominent literary institution in the state of Maine, situated at Brunswick, on an elevated plain S. of the village, about 1 m. from the Androscoggin river, and 4 m. from the shore of the Atlantic ocean. It was named in honor of Gov. James Bowdoin of Massachusetts. Prior to the revolution it had been proposed to establish a college in Maine, then a district of Massachusetts; but it was not till 1788 that a petition for a charter was presented to the Massachusetts legislature, from the association of ministers and the court of sessions for Cumberland county. The charter was granted in 1794, together with five townships as a foundation for the college, whose object, as stated in the act of incorporation, should be to "promote virtue and piety, and the knowledge of the languages and of the useful and liberal arts and sciences." The government was vested in two boards, one of trustees and the other of overseers, which met in 1801, and elected Joseph McKeen, D. D., a graduate of Dartmouth, for president

of the college, and John Abbott, a graduate of Harvard, for professor of languages. These officers were installed in 1802, when eight students were admitted, and in 1806 the first honors bestowed by the new institution were conferred upon eight graduates. A single building at this time served all the college uses, and also as the residence of the family of the president. President McKeen, dying in 1807, was succeeded by Jesse Appleton, D. D., who during the 12 years of his presidency contributed largely to the prosperity of the college. James Bowdoin, son of the governor, had before made a donation to the college of 1,000 acres of land and more than £1,100; and at his death in 1811 he left to it another donation of land, 400 models in crystallography, more than 500 specimens of minerals which had been arranged by Haüy, an elegant private library, and a costly collection of paintings. This gallery, since then much increased, is one of rare excellence, and the crystals and minerals were the nucleus of the large and valuable mineralogical and conchological cabinets which have been collected and arranged by Prof. Cleaveland. Upon the death of President Appleton in 1819, the Rev. William Allen, who had formerly been president of Dartmouth university, was elected his successor, and retained the office till 1839, with the exception of a short interval in 1831, when, being indirectly removed by an act of the legislature of Maine, which had now become a separate state, he contended against the authority of the state thus to control the college, and the question was decided in his favor by adjudication in the circuit court of the United States. President Allen was succeeded by Leonard Woods, D. D., who held the position till 1866. In 1867 the Rev. Samuel Harris, S. T. D., became president, and was succeeded in 1871 by Joshua L. Chamberlain, LL. D.—There are now eight college buildings, all large brick structures, excepting the chapel, which is of light granite, in the Romanesque style, and "Memorial Hall," of the same material. It was begun in 1846 and completed in 1855, and has rooms also for the library and picture gallery. The government of the college is vested in a board of 13 trustees and 40 overseers. Among the trustees are the president and vice president of the college. There is a visiting committee and an examining committee, each composed of two trustees and three overseers, and a finance committee of two trustees and two overseers. Besides the president, there are, including those in the medical school, 17 professors, 8 instructors, and 6 lecturers. During the year 1871-'2 the college had 163 undergraduates, 4 post-graduates, and 67 medical students; total, 234. The college year, divided into three terms, begins about the middle of September and ends on the second Wednesday of July, when the commencement exercises are held; there is a vacation of six weeks, beginning the last week in November, between the first and second terms, and one of a week in

April, between the second and third terms. The regular course of study comprises four years—all studies being required, except that for the third term of the junior year Italian and Greek are optional, and for the second term of the senior year Spanish is optional. Examinations are held at the end of each term. Besides the regular classical course, there is a scientific course for undergraduates. The degree of Sc. B. is conferred in this department. There is also a post-graduate course of two years in philosophy and the arts, in which are conferred the degrees of A. M., Sc. D., and Ph. D. Graduates who have completed any post-graduate course with honor may be appointed fellows, to reside at college, with all the privileges of the same, one or two years longer without charge. Instruction is given in military science, and daily exercises in drill are held, by an officer of the army detailed to perform these duties. The annual college expenses for each student are \$60 for tuition and \$10 for room rent. Ten scholarships, each yielding from \$50 to \$60 per annum, have been founded by individual benefactors, and there are several college scholarships. Assistance is furthermore afforded to students from a fund of \$6,000 given by Mrs. Amos Lawrence of Massachusetts, and one of \$2,000 given by Daniel W. Lord of Kennebunkport. The college has received no aid through legislative appropriation. The medical school of Maine was united with this college in 1821, and has now a complete anatomical cabinet and chemical apparatus, and a library of 4,000 volumes. The annual course of lectures, extending over a term of 16 weeks, begins early in January. The number of professors and instructors in the medical school in 1872 was 13; students, 67. The library of the college, together with those belonging to the societies of the students (exclusive of the medical library), contains 30,138 volumes. According to the triennial catalogue of 1870, the whole number of alumni was 1,677, of whom 1,150 survived; whole number of ministers, 316, living 227; whole number of doctors, 993, living 834. Parker Cleaveland, one of the earliest eminent mineralogists in America, was connected with the college from 1805 to 1858. Thomas C. Upham, D. D., held the position of professor of mental philosophy from 1824 to 1867. Nathaniel Hawthorne and Henry W. Longfellow graduated here in 1825, and among their contemporaries as students in the college were Luther V. Bell, G. B. Cheever, William P. Fessenden, John P. Hale, Franklin Pierce, S. S. Prentiss, and Calvin E. Stowe. Mr. Longfellow was the professor of modern languages from 1829 to 1835, when he was called to Harvard. The prevailing religious denomination at Bowdoin college is the Congregationalist.

BOWEN, Francis, an American author, born at Charlestown, Mass., Sept. 8, 1811. He graduated at Harvard college in 1833, and during four years was instructor there in intellectual philosophy and political economy. In 1843 he

succeeded Dr. Palfrey as editor and proprietor of the "North American Review," which he conducted till 1854. He was rejected in 1850 by the board of overseers of Harvard college as professor of history on account of his unpopular views on politics and on the Hungarian struggle for independence, but was almost unanimously confirmed in 1853 as Dr. Walker's successor in the Alford professorship of natural religion, moral philosophy, and civil polity. In 1848-'9 he delivered lectures before the Lowell institute on the application of metaphysical and ethical science to the evidences of religion (published in 1849; revised and enlarged edition, 1855); in 1850, on political economy; in 1852, on the origin and development of the English and American constitutions; and subsequently on English philosophers from Bacon to Sir William Hamilton. He supports Locke and Berkeley, and opposes Kant, Fichte, Cousin, Comte, and John Stuart Mill. Mr. Mill, in the third edition of his "Logic," makes elaborate comments on Mr. Bowen's antagonistic views. Among his works are: an annotated edition of Virgil; a volume of "Critical Essays on the History and Present Condition of Speculative Philosophy" (1842); an abridged edition of Dugald Stewart's "Philosophy of the Human Mind"; "Documents of the Constitution of England and America, from Magna Charta to the Federal Constitution of 1789" (1854); contributions to Sparks's "Library of American Biography"; "Principles of Political Economy applied to the Condition, Resources, and Institutions of the American People" (1856), in which he opposes the theories of Adam Smith, Malthus, and Ricardo, as inapplicable to the United States; and a revised edition of Reeve's translation of De Tocqueville's "Democracy in America" (2 vols. 8vo, 1862). In 1872 he made an extended tour in Europe.

BOWER BIRD, the name of two genera of conirostral birds of the starling family, peculiar to Australia. In the genus *ptilonorhynchus* (Kuhl) the bill is moderate, compressed, arched, and notched at the tip; the nostrils lateral, deeply sunk, with large opening partly concealed by projecting plumes; wings long and pointed, the first three quills graduated, and the fourth and fifth equal and longest; tail short and even; tarsi much longer than middle toe, robust and scaled; all four toes long and strong, with sharp claws. Two species are described by Gray, found chiefly in forests bordering the larger rivers of Australia, and in thick brushes of cedar; when perched on lofty trees they utter loud and harsh notes, somewhat resembling those of a domestic cat; they congregate in autumn in small flocks on the ground. The satin bower bird (*P. holosericeus*, Kuhl) is about the size of a jackdaw or small crow; in the adult male the plumage is deep satiny blue black, the primaries velvety black, and the wings and tail of the last color, edged with blue black; eyes light blue, with red circle around the pupil; bill bluish horn-colored,

yellowish at tip, and legs and feet yellowish white. The female is grayish green above, the wings and tail sulphur brown; yellowish below, each feather scaled with a dark brown border. The old males are more rarely seen than the females and young males, and the last do not get their glossy plumage till the second or third year. They feed on berries and fruits, especially wild figs and the native cherry, and they often attack the ripening crops of the settlers. The common name is derived from the singular habit which the females have of making very extraordinary bower-like structures, of various sizes, which are the most curious examples of bird architecture on record, displaying more ingenuity combined with taste than any other members of the class of birds. On the ground, generally under the shelter of trees in a retired place, they form a dome-shaped bower of sticks and twigs on a platform of the same materials; these are so interwoven that the tops of the twigs turn in and nearly meet at the top, the forks always pointing outward so as to offer no

Satin Bower Bird (*Ptilonorhynchus holosericeus*).

obstruction to the ingress and egress of the birds. But the most singular habit is the manner in which the bower is ornamented; they collect with great perseverance all kinds of brilliant and striking objects, such as the gaudy feathers of parrots, shells, skulls, and bleached bones of small animals, bright stones, and such high-colored rags as they can find about the houses of the natives and settlers; these they place at or near the entrances, introducing feathers between the interstices in the most fantastic and often in a very pleasing manner; so prone are these birds to pick up any odd-looking thing, that the natives always search their bowers, sure of finding many articles which they have missed from their scanty possessions. These bowers, according to Mr. Gould ("Birds of Australia," London, 1848), are not used as nests, but probably as assembly rooms, where many individuals of both sexes sport in the most playful manner; they are probably also used as places of rendezvous during pairing time, and for the elegancies and amusements

rather than the necessities of bird life. This species is the *courry* of the natives, and is found chiefly, if not only, in New South Wales; the male has a loud liquid call, besides the harsh note common to both sexes. The green satin bird (*P. Smithii*, Vig. and Horsf.) is rather smaller; the general color is a parrot green, with the ends of the wing coverts, secondaries, and most of the tail feathers tipped with white, and below with oval spots of the same. The food and the habitat are the same as in the last species, but it has not been ascertained that it makes a bower; it is called cat bird by the colonists, from the resemblance of its notes to the nightly concerts of the domestic cat.—The genus *chlamydera* (Gould) differs in having the nostrils exposed, a long and slightly rounded tail, and the third and fourth quills equal and longest. They are very shy birds, frequenting the forests and brushes of Australia; the food consists of fruits and seeds. They make still more remarkable bowers than the preceding genus, and the structures are longer and more avenue-like, made externally of interwoven twigs, and lined with tall grasses meeting above; they are decorated with bivalve shells, stones, small skulls, and whitened bones, the stones being arranged as a pavement, and so as to keep the grasses in place. The spotted bower bird (*C. maculata*, Gould) is about 11 inches long, the general color above being deep brown, each feather tipped with buff and edged with black on the head; the back of the neck is crossed by a broad frill of rosy pink elongated feathers; the lower parts grayish white; both sexes have the frill, except when young. In some of the larger bowers made by this bird, which had evidently been used for years, Mr. Gould has seen nearly half a bushel of shells and pebbles at each entrance, which had been brought from the shore at a considerable distance. The great bower bird (*C. nuchalis*, Gould) is about 15 inches long, and occurs in N. W. Australia; it is grayish brown above, satiny on the head, tipped with grayish white; on the nape a rosy pink frill partly encircled with a ruff of satiny plumes; yellowish gray below, tinged with brown; it makes highly ornamented bowers.

BOWIE, a N. E. county of Texas, separated on the north from the Indian territory and Arkansas by the Red river, bounded E. by Arkansas and S. and S. W. by the Sulphur fork of Red river; area, 892 sq. m.; pop. in 1870, 4,687, of whom 2,249 were colored. The surface is undulating, and in many places covered with thick forests of post oak and other timber. The soil of the bottoms is rich red land, well suited to cotton; in other localities it is sandy. Lignite coal and iron ore are found. There are several mineral springs. The chief productions in 1870 were 104,805 bushels of Indian corn, 11,223 of sweet potatoes, 2,990 bales of cotton, and 4,757 lbs. of honey. There were 772 horses, 1,501 milch cows, 4,178 other cattle, 578 sheep, and 7,011 swine. Capital, Boston.

BOWLDERS, or **Boulders**, loose rounded blocks of stone, named by the French *blocs erratiques*, found scattered over the surface in high northern and southern latitudes, extending to within 35° or thereabouts of the equator. In the northern hemisphere they are always of the varieties of rock which are found in solid ledges in a northerly direction; and in the southern hemisphere the ledges are again met with toward the pole. These loose rocks appear in each case to have been transported toward the equator, either by glaciers or by icebergs, and to have been subjected to rolling action, which has rounded off their corners and ground their surfaces. (See *DILUVIUM*.) The size of these transported blocks is often enormous. At Fall River, Mass., on the S. side of the bay at the mouth of Taunton river, a boulder of conglomerate rock was uncovered in the gravel resting on granite ledges which was estimated to weigh 5,400 tons. The ledges of this conglomerate are met with only on the other side of the bay. Along the coast of New England the bowlders constitute by their great numbers and size a marked feature in the landscape. They are sometimes found perched upon bare ledges of rock, and so nicely balanced that, though of great weight, they may be rocked by the hand. These are called rocking stones. "Plymouth Rock" is a boulder of sienitic granite, ledges of which are found in the towns near Boston. The highest mountains are often covered with these bowlders of the drift formation. Upon the bare granite summit of Mt. Katahdin—the highest mountain in Maine—at an elevation of 3,000 feet or more above the surrounding valleys, pieces of limestone containing fossil shells are found, though no ledges resembling them are known except many miles to the northwest, and at a much lower level. The northern and central parts of Europe are equally interesting for the distribution of bowlders. The pedestal of the statue of Peter the Great at St. Petersburg was hewn out of a granite boulder, weighing about 1,500 tons, that lay on a marshy plain near the city. Upon the limestone ledges of the Jura mountains are found bowlders of granite which must have come from the higher Alps, where ledges of similar character are found. Some of these bowlders are of very large dimensions, one in particular, known as the *pierre à Martin*, according to Mr. Greenough, measuring no less than 10,296 cubic feet, and weighing consequently about 820 tons.

BOWLES, Caroline. See **SOUTHEY**.

BOWLES, Samuel, an American journalist, born in Springfield, Mass., Feb. 9, 1826. His father was proprietor of the "Weekly Republican" newspaper at Springfield, and the son became at an early age an apprentice in the office. In 1844 he induced his father to establish a daily newspaper, of which he became, though only 18 years of age, virtual editor. He has held this post ever since, and under his charge the "Springfield Republican" has

risen to prominence. Mr. Bowles has made several journeys in the region lying between the Mississippi and the Pacific, the first in 1865 with a large company, among whom was Mr. Schuyler Colfax. The observations made on this journey, originally written in the form of letters to his journal, appeared in a collective form under the title "Across the Continent" (1865). In 1869 he published two works, "Our New West" and "The Switzerland of America," the latter describing the natural parks and the mountains of Colorado.

BOWLES, William Augustus, an American adventurer, born in Frederick co., Md., in 1763, died in Havana, Dec. 23, 1805. His father was an English schoolmaster who had established himself in Maryland. When 18 years of age young Bowles ran away from home and joined the British army at Philadelphia. He obtained a commission, and was for some time stationed at Pensacola; but for a breach of regulations he was dismissed the service. Soon afterward he became connected with the Creek Indians, and married a woman of the tribe, in which he became an acknowledged leader. He encouraged their excesses and prompted them to many attacks on the Spaniards, in which he was sustained by the approval and even rewards of the British government. He commanded the Creeks when they assisted the British at Pensacola in May, 1781, and for his conduct on that occasion was restored to his place in the army. After the war he led a roving life—at one time an actor and again a portrait painter—until he was appointed by Gov. Dunmore leading agent for his old Indian allies, when he established himself at Chattahoochee. McGillivray, who had led the Creeks during the revolution, drove him from his agency, and he went to England for a time; but on his return he was again made commander-in-chief of the tribe, and used his influence with such effect against the Spaniards that they offered \$6,000 for his capture. After disturbing the peace of Georgia for several years, he was taken in 1792 by the Spaniards, and sent to Madrid and afterward to Manila. He escaped, and for a time returned to his old allies; but he was finally recaptured in 1804, carried to Havana, and confined in the Morro castle till his death.

BOWLES, William Lisle, an English poet and clergyman, born at King's Sutton, Sept. 24, 1762, died in Salisbury, April 7, 1850. After attending Westminster school he entered Trinity college, Oxford, where he graduated in 1787. Disappointed in the expectation of a living, and much depressed by the death of a lady to whom he was engaged to be married, he made, soon after leaving the university, an extended journey in Great Britain, during which he composed the "Fourteen Sonnets" forming his first published work, which were much admired. They were followed by several less important writings, and in 1804 by his "Spirit of Discovery," a poem

in six books. In 1807 he published an edition of Pope's works in 10 volumes. From this time new works appeared in rapid succession, and comprised a great number of poems, of which the "Missionary of the Andes," published in 1815, acquired the greatest fame. He continued a prolific writer of verse and prose till 1837, when he seems to have retired from literary life. In the mean time he had received important preferment in the church, having been made rector of several parishes, in 1818 chaplain to the prince regent, and in 1828 canon of Salisbury cathedral. He was a man of eccentric habits, very absent-minded, and singularly timid. Bowles's edition of Pope, containing an essay with some severe comments on the poet, gave rise to a discussion which has become historical as "the Pope and Bowles controversy." In it Byron was his principal opponent, but Campbell, Gilchrist, and others were warmly engaged in it. Bowles defended his opinions with great ability.

BOWLING, or **Bowls**, an ancient athletic game, played with balls of different shapes rolled on a flat expanse of turf in the open air. The name is also sometimes applied to a modern American game more commonly called **tenpins**, which but slightly resembles the ancient sport, from which it is nevertheless undoubtedly derived. **L** The ancient game of bowls, still a favorite pastime in Great Britain, requires, in order that it may be played with skill, the most careful preparation of the ground, called a bowling green, on which the turf must be closely shaved, watered, and rolled. It must be surrounded by a shallow trench. The balls (called bowls) which are used by the players are of hard wood, generally *lignum vitae*, six or eight inches in diameter, but are not exactly spherical, having a bias to one side. A small white spherical ball, called the jack, is placed at one end of the green, and the players endeavor so to roll their bowls that they shall fall as near as possible to this conspicuous mark. The irregular shape of the bowl makes it very difficult for a novice to calculate its course, and renders necessary a peculiar motion in rolling it. The players are generally arranged in sides, every man of each side having two bowls. The side which places its bowls nearest the jack counts one point in the game for each bowl so placed. The number making game is settled by the players before beginning. With unimportant variations, this method of playing bowls has been in use in Great Britain for centuries. The game has been the subject of several legislative enactments, having been prohibited altogether during the reign of Henry VIII., by a law repealed in 1845. Bowls was formerly a favorite game with the Dutch. The early inhabitants of New York city (in their time New Amsterdam) made it a common recreation, and the ground they used for play, at the lower end of Broadway, near the Battery, is now a small ornamental park, which still bears the name of the Bowling Green.

II. The modern game of **tenpins** or **bowling** is practised in saloons, on alleys of carefully fitted carpenter's work, from 50 to 65 ft. in length, and about 4 in width. The alley has a gutter, as it is termed, on each side, and is very slightly convex in the centre, regularly bevelled to the sides. At the further extremity are set up 10 pins, usually of ash wood, about a foot in height and 2 or 2½ lbs. in weight, arranged in the form of a pyramid, with the apex toward the bowler. The apex consists of a single pin, the 2d rank of 2, the 3d of 3, and the 4th of 4, the last occupying the whole width of the alley, and the first standing on the crown of it. All the pins are equidistant from each other. At these the bowler rolls wooden balls, perfectly spherical and usually of *lignum vitae*, from 4, 5, or 6 lbs., down to half a pound in weight, with the object of knocking down as many of the pins as possible at each roll. The pins, when set up, are called a frame; and at each frame the bowler rolls three balls, when the number of pins down is counted to him, and the frame is set up again for the next bowler. A game ordinarily consists of 10 frames, or 30 balls. If the bowler takes all the pins with his first ball, he counts 10; this is called a "ten-strike;" the frame is again set up for his second ball, when, if he again takes all, he counts 10 more, and the frame is again set up for his third, when whatever number he scores with the three balls counts to him as if all had been made off one frame. If he takes all the 10 with his first two balls, he is entitled to a fresh frame for his third or last ball; this is called a spare. It is now everywhere customary to employ a somewhat complicated method of counting gains thus made. By this arrangement, when a player gets a ten-strike or spare, he does not immediately have the frame set up for him especially, and proceed to roll the remaining one or two of his three balls while the other players wait for him; but in order to save time and the labor of unnecessary resetting, he waits till his next regular turn comes, and then counts the first ball or first two balls of it doubly—i. e., both as additions to his former ten-strike or spare, and as new counts for himself.

BOWLING GREEN, a town and the capital of Warren co., Ky., on Barren river, 120 m. S. W. of Frankfort; pop. in 1870, 4,574, of whom 1,670 were colored. The river is navigable to this point by steamboats of 200 tons, and regular lines run to Louisville. The Louisville and Nashville railroad passes through the town. Its trade, chiefly in pork and tobacco, is considerable, and there are a number of mills, and some manufactories of iron, woollens, &c. There are several churches and schools, and a weekly newspaper. At the beginning of the civil war it was regarded as a point of great strategic importance, and was occupied by Gen. Buckner in September, 1861, with a force of 10,000 confederates, which was subsequently largely increased, for the purpose of defending the ap-

proach to Nashville. After the capture of Fort Henry by the federal troops (Feb. 6, 1862), the confederates found themselves outflanked, and were obliged to evacuate the town.

BOWMAN, Thomas, D. D., an American clergyman, born near Berwick, Columbia co., Penn., July 15, 1817. He was educated at Wilbraham academy, Mass., at Cazenovia seminary, N. Y., and at Dickinson college, Carlisle, Penn., where he graduated in 1837. After studying law at Carlisle for one year, he entered the ministry in the Baltimore conference of the Methodist Episcopal church in 1839. From 1840 to 1848 he taught in the grammar school of Dickinson college. In 1848 he was appointed to organize the Dickinson seminary at Williamsport, Penn. Over this institution he presided for ten years, and during this period became distinguished as a pulpit orator. In 1858 he was elected president of Indiana Asbury university at Greencastle. He was elected delegate to the British conference in 1864, and was chaplain of the United States senate in 1864 and 1865. He continued to preside over the Indiana Asbury university till May, 1872, when he became a bishop. His residence is St. Louis, Mo.

BOWRING, Sir John, an English statesman and author, born at Exeter, Oct. 17, 1792, died Nov. 22, 1872. He early applied himself to the study of modern languages, and between 1821 and 1824 published metrical translations of the popular poetry of Russia, Holland, and Spain, and afterward of Poland, Servia, Hungary, Portugal, Iceland, and Bohemia. About 1822 he made the acquaintance of Jeremy Bentham, became his disciple, executor, and biographer, and edited his works (11 vols. 8vo, 1848). In 1825 he was made first editor of the "Westminster Review," and continued in this position for several years, writing copiously in support of parliamentary reform and free trade. He travelled in Holland in 1828, and received the honorary degree of LL. D. from the university of Groningen. In 1838 he published "Matins and Vespers, with Hymns," a volume of original poetry, chiefly devotional. He wrote with Villiers "On the Commercial Relations between France and Great Britain" (2 vols., 1834-'5), the result of official investigation, and was employed in similar labors relating to Switzerland, Italy, the Levant, and the German customs union. As a member of parliament from 1835 to 1837, and again from 1841 to 1849 he invariably advocated extreme liberal opinions, and was one of the counsel of the anti-corn law league. In January, 1849, he was appointed British consul at Canton, and subsequently he became acting plenipotentiary. He returned to England for a short time in 1853, and published two volumes in support of a decimal system of coinage. In 1854 he was knighted and appointed governor of Hong Kong. Parliament censured his course in the bombardment of the Chinese forts in 1856, and he was recalled in 1857. His "Kingdom of Siam and its People" (2 vols., London, 1857) embodies his observa-

tions while on a mission in that country for the conclusion of a commercial treaty. "A Visit to the Philippine Islands in 1858-'9" appeared from his pen in 1859. He was a zealous Unitarian, and in 1872 was prominent in the international social reform convention in London.

BOWYER, William, an English printer and scholar, born Dec. 19, 1699, died Nov. 18, 1777. He studied at Cambridge, and became printer to the house of commons and various learned societies. He published several learned works, the most celebrated of which was a Greek edition of the New Testament, with critical and emendatory notes (2 vols., 1763; 2d ed., 1812). His memoirs are included in "Nichols's Literary Anecdotes of the Eighteenth Century" (9 vols., 1812-'15; continued as "Illustrations of Literary History," 1817-'48).

BOX (*buxus*), a shrubby evergreen tree, which affords a very valuable close-grained wood. The Romans cultivated the box tree as an ornamental shrub in their gardens, and consecrated

Box Tree.

it to Ceres. The Greeks called it *πύθος*, whence the Latin name; and as the same Greek word signifies goblet or vase, it is probable that they named it from its use in the manufacture of small cups and ornaments. *B. sempervirens*, the best known species, is the most northern arborescent plant of the natural order *euphorbiaceae*, the other trees of that order being found only in mild or tropical climates. It is a native of most parts of Europe, is common from England to Persia, and attains in favorable localities the height of 15 or 20 ft., but in some rocky regions never rises above 3 ft. It has small oval and opposite leaves, male and female flowers upon the same individual, and a 3 or 4-parted calyx. Among the garden varieties is the dwarf box, much used for the edgings of walks. The wood is of a yellowish color, hard, heavy, durable, close-grained, and susceptible of a high polish. It has a specific gravity of

1:328. It is prepared for industrial uses by steeping large blocks in water during 24 hours, after which it is boiled in water, and then allowed to dry slowly, immersed in sand or ashes

Leaves and Fruit of Box.

to exclude the air and prevent rapid desiccation. It is much used by the turner, the mathematical instrument maker, and the wood engraver, and for certain uses no other kind of wood can replace it with advantage. It is sent in large quantities from Spain to Paris, and great quantities of a very fine quality are imported from the Levant into the manufacturing countries of Europe. The *B. Balearica*, or Majorca box, is a handsomer plant than the preceding, having wide leaves, but requires a warmer climate or more careful culture. It will grow, however, in the open air, in the milder exposures of northern latitudes. It abounds on the hills of Majorca at the height of 1,500 ft. above the level of the sea, and is supposed to furnish a part of the Spanish and Turkey box wood. Box wood is sometimes used in medicine as a substitute for guaiacum, and the leaves have been employed as a substitute for Peruvian bark. The leaves have also been used instead of hops in the brewing of beer, but they give an acrid, unpleasant flavor to the liquor.

BOX ELDER, a N. W. county of Utah, bounded N. by Idaho and W. by Nevada; area, 6,000 sq. m.; pop. in 1870, 4,855, of whom 403 were Chinese. About half of Great Salt lake lies in the S. E. part of the county. Bear river flows through the E. part. The surface is broken. The Central Pacific railroad traverses the county. The chief productions in 1870 were 26,972 bushels of wheat, 4,539 of Indian corn, 2,324 of oats, 4,240 of barley, 10,692 of potatoes, 1,784 tons of hay, 3,394 lbs. of wool, and 3,910 gallons of sorghum molasses. There were 434 horses, 801 milch cows, and 2,582 sheep. Capital, Brigham City.

BOXING. See PUGILISM.

BOYACÁ. I. An inland state of the United States of Colombia, divided into the provinces of Pamplona, Casanare, Socorro, and Tunja, and bordering upon Venezuela and the states of Cundinamarca and Santander; area, 83,349 sq. m.; pop. in 1870, 482,874. The capital is Tunja, once the court of the Zaque kings, the implacable enemies of the Zipas of Bogotá. The face of the country is traversed in the west by a chain of the Andes, and slopes toward the east into immense *llanos* or plains, little cultivated, and covered in part by dense forests and marshes, and in part by luxuriant pastures watered by the Meta and other tributaries of the Orinoco. Along the banks of the former river are almost the only inhabitants to be found in this region. The S. part of the state is intersected by morasses. The soil in some places is remarkably fertile; the lowlands yield in abundance all the tropical fruits and vegetables, as also cotton, cacao, sugar, tobacco, dyes, medicinal drugs, and an infinite variety of useful timber. The productions of the highlands are similar to those of Europe. Honey is plentiful, and the preserves from this state are much esteemed. Vapors from numerous thermal springs in the south are condensed in dry weather and cover the surrounding fields with sulphate of soda, which is sold in the plains for the use of cattle at a high price. Near Tunja there are springs cold by day and very hot by night. The climate on the plains is hot and unhealthy, and fevers are common; in the valleys of the west and centre, though warm, it is very salubrious; in the highlands it is much cooler, but, as in most alpine regions, the inhabitants suffer very much from goitre, due in some localities to the use of impure water. Coarse cotton and woollen cloths, blankets, and flannels are manufactured, as also straw hats; and there are dyeworks, powder mills, tanneries, and spinning mills, and a considerable internal traffic. Cattle are extensively raised. Emeralds and some gold are found, but the mines are no longer worked. There are some lead mines in Socorro, as also fossil remains of colossal mammals. The forests are infested by jaguars, wild cats, *mapurites* (species of badger), hideous snakes, *coyas* (venomous spiders), and green mosquitoes formidable on account of a worm which they deposit in the skin whenever they bite. II. A small town of the above described state, on the road from Tunja to Bogotá, 12 m. from the former, in lat. 5° 20' N., lon. 73° 39' W. It is celebrated for the victory gained by the forces of New Granada, commanded by Bolívar, over the Spaniards, the whole of whose surviving troops, with arms, ammunition, and baggage, fell into the hands of the victor. This battle, fought Aug. 7, 1819, near the bridge of Boyacá, was decisive of the independence of New Granada. A college was established here in 1821.

BOYAR, or **Bolar** (from *boi*, battle), a Slavic title, first especially used by the Bulgarians,

Serbs, and Russians, and afterward by the Moldavians and Wallachians. It represented the highest social condition, corresponding in certain respects to that of an English peer. In ancient Russia the boyars were the next after the princes of the blood, and formed a kind of supreme political body, acting as the council of the grand dukes. All the higher offices, civil and military, including the lieutenancies in the provinces, were held by them. While Russia was divided into petty sovereignties, the boyars enjoyed the right of choosing for themselves and for their dependants the prince whom they wished to serve, and of leaving his service at pleasure. When the grand dukes of Vladimir and of Moscow stripped these petty princes of their sovereign rights, the dignity of boyars was granted to them, and their influence often equalled that of the grand dukes, the ukases always containing the words, "approved by the boyars." Precedence among the boyars was according to the creation of the title, which was hereditary; and in the 16th and 17th centuries any boyar of an older creation refused to serve under one of a younger. This struggle for precedence, which was especially troublesome in times of war, was ended by Fedor III., and Peter the Great wholly abolished the dignity of boyar. In Roumania the boyar nobility, though not of national origin, sat in the council of the hospodars, and exercised a preponderating influence till 1864, when it was checked by Prince Cuza.

BOYCE, Hector. See BORTHUIS.

BOYCE, William, an English composer, born in London in 1710, died in February, 1779. He was the son of a mechanic, and was placed under the tuition of Charles King, choir master of St. Paul's cathedral. When his voice changed he commenced the study of harmony and the organ, and became organist first at the Oxford chapel, and subsequently at St. Michael's, and composer for the royal chapel. He received the degree of doctor of music from Cambridge university in 1749. In 1758 he became conductor of the royal orchestra, directing in that capacity the music at the triennial gatherings of the cathedral choirs of Worcester, Hereford, and Gloucester. His principal compositions are church services, which are still held in high esteem and are in constant use both in England and the United States. Several years of his life were devoted to the collection and publication in score of the best works of the composers of English church music from the earliest times to his own. He wrote also 12 trios for two violins and bass, eight symphonies, and many anthems of much excellence. One of the latter, "Blessed is he that considereth the poor," is sung every year at the festival given for the sons of the clergy. He also wrote two musical dramas entitled "The Chaplet" and "The Shepherd's Lottery." He was buried in St. Paul's cathedral.

BOYD, a N. E. county of Kentucky, separated on the N. E. from Ohio by the Ohio river, and

on the E. from West Virginia by Big Sandy river; area, 230 sq. m.; pop. in 1870, 8,573, of whom 291 were colored. The surface is generally hilly. Iron ore and stone coal are abundant. The chief productions in 1870 were 11,718 bushels of wheat, 168,199 of Indian corn, 17,968 of oats, 12,598 of potatoes, and 1,269 tons of hay. There were 850 horses, 945 milch cows, 1,908 other cattle, 3,843 sheep, and 3,999 swine. Capital, Catlettsburg.

BOYD, Andrew Kennedy Hutchison, D. D., a Scottish clergyman and essayist, born at Auchinleck, Ayrshire, in November, 1825. He was educated at the university of Glasgow; became a minister of the established church of Scotland in 1851, and officiated successively in the parishes of Newton-on-Ayr, Kirkpatrick-Irongray in Galloway, St. Bernard's in Edinburgh, and at St. Andrews, where he still remains. His writings, which originally appeared in magazines, have been republished separately. They include "Recreations of a Country Parson" (two series, 1860 and 1861), "Leisure Hours in Town" (1862), "Graver Thoughts of a Country Parson" (1863), "Counsel and Comfort Spoken from a City Pulpit," "Autumn Holidays of a Country Parson," and "Present Day Thoughts" (1870).

BOYD, John Parker, an American soldier, born in Newburyport, Mass., in 1768, died in Boston, Oct. 4, 1830. He entered the United States army in 1786, but soon afterward went to India, where he raised three battalions, each of about 500 men, with a few English officers, whom, as well as his men, he hired at a certain amount per month. The equipment, including guns and elephants, was his sole property, and he let out the services of his little army to any of the Indian princes who would give him the best pay. The demand for his services diminishing, he sold out, and in 1808 returned to the United States, and took part as colonel in the battle of Tippecanoe, Nov. 7, 1811. He was afterward appointed brigadier general, put at the head of a detachment of 1,500 men of Wilkinson's army in the expedition to Upper Canada, and fought the battle of Chrysler's Farm, Nov. 11, 1813. He published "Documents and Facts relative to Military Events during the late War" (1816).

BOYD, Mark Alexander, a Scottish scholar and soldier, born at Galloway, Jan. 18, 1562, died at Pinkill, April 10, 1601. His headstrong temper made him quarrel with his relatives and instructors, and before he had finished his academic course he sought his fortune at court, where one duel and numberless broils soon made him notorious. He went to France, where he studied civil law, and thence to Italy. In 1587 he joined the Catholic league as a volunteer soldier, though himself a Protestant; but in 1588 he resumed his legal studies at Toulouse, where he was imprisoned for his religious opinions. He was permitted to escape to Bordeaux, and for some years his life alternated between war and study. His

elder brother's death in 1595 induced him to return to Scotland. He had previously endeavored to win the favor of James VI. by dedicating to him a volume of Latin poems, published at Antwerp in 1592. Some other of his Latin poems are to be found in the *Delicia Poetarum Scotorum*. He was a thorough master of Greek, and translated Oæsar's Commentaries into that language. Lord Hailes wrote a "Sketch of the Life of Boyd" (1783).

BOYD, Zachary, a Scottish divine, died in Glasgow about 1653. He studied in Scotland and France, became professor at Saumur, and after his return home on account of the persecutions of the Protestants, he was pastor of the parish church and thrice rector of the university of Glasgow. He wrote many works, chiefly polemical, among which is "The Last Battell of the Soule in Death" (2 vols., Edinburgh, 1629; new ed., with his biography by Gabriel Neil, Glasgow, 1831). He also wrote the metrical paraphrase of the Scriptures popularly called "Zachary Boyd's Bible," bequeathed, with many other manuscripts and a large sum of money, to the university of Glasgow, in whose library it remains in MS.

BOYDELL, John, an English engraver and print publisher, born Jan. 19, 1719, died in London in December, 1804. He was educated for the church, but apprenticed himself in 1740 for seven years to a London engraver. His first publication was the "Bridge Book," so called because there was a bridge in each of the views which it contained. In 1746 he published by subscription a volume of engravings, wholly executed by himself, containing 152 views in England and Wales. The profits of this volume enabled him to become a regular publisher, and to employ good artists; and in a few years the engravings of Boydell were largely exported to the continent. He established the "Shakespeare Gallery" in Pall Mall as an English school of historical painting, and employed Reynolds, Opie, West, Northcote, and other eminent painters, in illustrating Shakespeare's works. From these pictures the best engravers produced the celebrated work (3 feet by 2 in. size), in royal elephant folio, entitled "A Collection of Prints from Pictures painted for the purpose of illustrating the Dramatical Works of Shakespeare." It appeared in 1803 (having been preceded, in 1792-1801, by Boydell's edition of Shakespeare, printed by Bulmer, 9 vols. folio), and the sum of £350,000 had been expended upon it. When he commenced this project, he had every reason to expect that, as with his previous productions, his foreign customers would take a considerable number of copies. But the war had injured foreign trade, and in 1804 he was compelled to solicit parliament to authorize him to dispose of the original paintings by lottery. He was alderman of London in 1782, sheriff in 1785, and lord mayor in 1790. The plates of Boydell's illustrations of Shakespeare were purchased in a damaged condition by an Ameri-

can, Dr. S. Spooner, brought to the United States, and retouched, and a new edition was printed from them.

BOYER, Abel, an English historian and lexicographer, born at Caestre, France, June 13, 1664, died at Chelsea, Nov. 16, 1729. He was a French Protestant refugee who settled in London in 1689, and was for some time a teacher. He figures in Pope's "Dunciad," and compiled the "Political State of Great Britain," a monthly publication, continued till 1740, making 60 vols. 8vo.; "Annals of the Reign of Queen Anne" (11 vols.); "History of William III." (8 vols.); and, besides other works, published a "Life of Sir William Temple" (1714). He also wrote a French-English dictionary and grammar, which remained in very general use almost to the present time.

BOYER, Alexis, baron, a French surgeon, born at Uzerche, Limousin, in March, 1757, died in Paris, Nov. 25, 1833. He was the son of a poor tailor, went to Paris as assistant to a drover, and acquired his first knowledge of surgery while employed as a barber. In 1795 he became professor of operative medicine, and afterward chief surgeon of Napoleon, who made him a baron with a revenue of 25,000 francs, which he lost after the restoration, though remaining in the service of Louis XVIII., Charles X., and Louis Philippe. He succeeded Deschamps in 1825 as chief surgeon of the Charité, and a member of the institute of France. His best works are, *Traité complet d'anatomie* (4 vols., Paris, 1797-'9), and *Traité des maladies chirurgicales* (11 vols., 1814-'26), of which many editions have appeared in France, and translations in Germany. With Corvisart and Roux he edited the *Journal de Médecine, Chirurgie et Pharmacie* (1798-1817).

BOYER, Jean Pierre, a mulatto general and president of Hayti, born in Port-au-Prince in February, 1776, died in Paris, July 9, 1850. He was educated in France, and on his return to Hayti joined the revolted blacks, then struggling against the French for their independence. When the French gave up Fort St. Nicolas to the English, Boyer fought against the latter, and distinguished himself in the defence of the fort of Biron, and in other dangerous enterprises. Soon afterward Toussaint l'Ouverture separated from the mulattoes, and Boyer, Pétion, and others, retired to France. Boyer was appointed by Bonaparte a captain in the expedition fitted out in 1801, under Gen. Leclerc, and after its disastrous termination left the French service. In 1806 he served under Pétion as commander of Port-au-Prince, and repelled the attacks of Christophe, who held part of the island with the title of emperor. At the death of Pétion in 1818, Boyer was elected president; and after the death of Christophe in 1820, the empire was united to the republic. In 1824 Boyer annexed Santo Domingo, the Spanish part of the island, thus uniting the whole of Hayti. The country advanced during the earlier years of his adminis-

tration, but afterward he became arbitrary and reckless. Intimidated in 1825 by the appearance of a French squadron, he submitted to the claims of France, who demanded a monopoly of the trade and a compensation of 150,000,000 francs for the confiscated estates of the white planters. The Haytians, oppressed by the debt he had foolishly brought upon them, rose in rebellion against him in 1842. He fled to Jamaica, and after the outbreak of the French revolution of Feb. 24, 1848, went to Paris, where he died.

BOYLE, a central county of Kentucky, bounded N. E. by Dick's river, a branch of the Kentucky; area, 180 sq. m.; pop. in 1870, 9,515, of whom 3,679 were colored. The Lebanon branch of the Louisville and Nashville railroad passes through it. Danville is connected with Lexington by the Kentucky Central railroad. The surface is diversified, and the soil deep and rich, underlaid by extensive beds of limestone. The chief productions in 1870 were 99,316 bushels of wheat, 14,789 of rye, 272,505 of Indian corn, 58,115 of oats, and 14,481 gallons of wine. There were 23,035 horses, 1,496 milch cows, 4,358 other cattle, 3,811 sheep, and 12,663 swine. Capital, Danville.

BOYLE, a town, parish, and barony of Ireland, in the county of Roscommon, 108 m. N. W. of Dublin; pop. of the town about 4,000. The river Boyle divides it into a new town, which is well built and has a handsome sessions house, and an old town, with the remains of Boyle abbey and other ancient buildings. The old manor house of the King family is used for barracks. The Irish "Annals of Boyle," extending from 420 to 1245, have been published in English and Latin.

BOYLE. I. Richard, earl of Cork, an English politician, born at Canterbury, Oct. 3, 1566, died Sept. 15, 1643. He was born a commoner, and became clerk to Sir R. Manwood, chief baron of the court of exchequer. Not seeing any prospect of advancement, he went to Ireland, where he married a lady who died and left him a landed estate worth about £500 a year. His abilities, and the growth of his possessions, raised him up a host of enemies and detractors; and the rebellion of Munster reduced him to poverty. He returned to England, and visiting Ireland again in the suite of the earl of Essex, his presence renewed the malice of his detractors, who having brought formal charges against him, he pleaded his cause with such force before Elizabeth in person that the queen took him into favor. He was made clerk of the council of Munster, and bought considerable estates, which he colonized with Protestant tenants, and managed so well as to call forth a remark from Cromwell, that had there been an earl of Cork in each county there had been no rebellion. In 1616 he was created Baron Boyle of Youghal, in 1620 earl of Cork, and in 1631 lord high treasurer of Ireland, which office was made hereditary in his family.

His "True Remembrancer of his Life" is included in Dr. Birch's "Life of Robert Boyle" (London, 1766). **II. Roger**, third son of the preceding, born in Ireland, April 26, 1621, died Oct. 16, 1679. He was known as Lord Broghill during the protectorate, and earl of Orrery in the reign of Charles II. He was won to the cause of the commonwealth in Ireland by Cromwell, at a period when he was known to be engaged in favoring the return of Charles II., and was of material assistance in reducing Ireland to subjection. After the protector's death he was one of Richard Cromwell's privy council, but favored the restoration of Charles II. He wrote a romance, "Parthenissa" (3 vols., 1665), and many tragedies, comedies, and poems, besides "State Letters," published in 1742. **III. Robert**, 5th son and 14th child of the first earl of Cork, born at Lismore castle, Ireland, Jan. 25, 1626, died in London, Dec. 30, 1691. At Eton, whither he was sent at nine years of age, he showed irregular application and development, and after four years was placed under the care of private tutors. With M. Marcombes, a Frenchman, he travelled on the continent. He returned to England in 1644, his father having meanwhile died, and left him property in Ireland and the Stalbridge estate, where he chiefly resided from 1646 to 1650, occupied in study, especially of chemistry. At this time he was one of a society of learned men, called by him the "Invisible College," out of which ultimately grew the royal society. In 1652* he went to Ireland on private business. After his return he resided at Oxford for the most part, using its advantages for study, and associating with men of science in their investigations, till 1668, when he settled in London, at the residence of his elder sister, Lady Ranelagh. He has been called the inventor of the air pump, which was perfected for him in 1658 or 1659 by Robert Hooker, then his chemical assistant, and by it Boyle demonstrated the elasticity of the air. He also associated and corresponded with eminent oriental and Biblical scholars. On the restoration Boyle was favorably received at court, and urged to enter the church; but he thought he could serve religion better as a layman, and published in 1660 "Some Motives and Incentives to the Love of God," which was several times reprinted and translated into Latin. In 1662 a grant was made him of a lease of forfeited impropriations in certain parishes in Ireland, but he relinquished all private benefit, and appropriated two thirds of the net proceeds to the wants of the parishes, and printed the church catechism and the New Testament in Irish at his own expense. The other third he gave to the society for propagating the gospel in New England, of which he was afterward made governor. In 1663 he was one of the first council of the newly incorporated royal society. He became a director of the East India company, helping to procure its charter. In 1676 he wrote a letter

pressing upon that body the duty of promoting Christianity in the East, and in 1677 he caused the Gospels and the Acts to be translated into Malay at his cost by Dr. Thomas Hyde, and gave a large reward to the translator of Grotius's *De Veritate* into Arabic. A selection of his works was published in Latin at Geneva in 1677, though without his consent or knowledge. In 1680 he was elected president of the royal society, but declined from a conscientious scruple. He gave pecuniary aid to Burnet while the latter was compiling his "History of the Reformation." The revolution cut off his resources from Ireland, and his health being impaired, he resigned his presidency of the society for the propagation of the gospel in 1689. His sister, with whom he had lived for 23 years, died in 1691, and he did not survive her a week. Boyle was tall, pale, and of delicate health. He never married. His habits were very careful, regular, and abstemious, and he was noted for reverential piety. His philosophical experiments gave him a very high reputation in science, and he has been called "the great Christian philosopher." His works, with an autobiography, were published in London in 1744, in 5 vols. folio. Among them may be mentioned the "Disquisition into the Final Causes of Natural Things," "Free Inquiry into the received Notions of Nature," "Discourse of Things above Reason," "Considerations about the Reconcilableness of Reason and Religion," "Excellency of Theology," and "Considerations on the Style of Scripture."

IV. Charles, 4th earl of Orrery, born at Chelsea in August, 1676, died in August, 1731. He was the great-grandson of the first earl of Cork, and second son of the second earl of Orrery. He was educated at Christ Church, Oxford. An edition of the epistles of Phalaris, the preface of which contained a disparaging allusion to Richard Bentley, having been published under his name, he became complicated in a famous controversy between Bentley, Atterbury, and others scholars. (See BENTLEY, RICHARD.) In 1700 Mr. Boyle was elected to parliament, and in 1703 he succeeded to the title of earl of Orrery. He served as major general under Marlborough in Flanders, and after the treaty of Utrecht in 1713 was sent as envoy to the states of Brabant and Flanders, and created a peer of Great Britain as Lord Boyle. Under George I. he was one of the lords of the bedchamber, but in 1722 was confined six months in the tower for high treason as an accomplice in Sayer's plot. In the latter part of his life he amused himself with philosophical subjects. It was in his honor that George Graham, the inventor, gave the name of the orrery to the instrument exhibiting the planetary revolutions. **V. John**, only son of the preceding, born Jan. 2, 1707, died Nov. 16, 1762. He succeeded his father as earl of Orrery in 1731, and in 1753, on the death of his second cousin, became fifth earl of Cork. In the house of lords he constantly opposed the administration of Sir Robert Walpole. He

edited the dramatic works and state papers of the first earl of Cork, Pliny's letters, and the "Life of Robert Cary, Earl of Monmouth" (1759), and contributed to various periodical publications; but he is best known by his "Remarks on the Life and Writings of Dr. Jonathan Swift, in a Series of Letters" (London, 1751), the publication of which brought upon him a great deal of censure.

BOYLSTON, Zabdiel, an American physician, born at Brookline, Mass., in 1680, died in Boston, March 1, 1766. In 1721, when the smallpox appeared at Boston, the attention of the faculty was called by Cotton Mather to inoculation. Dr. Boylston, the only member of that body who did not treat the communication with disdain, commenced the practice successfully in his own family, and extended it to other cases. But the opposition to the new process was so stubborn that the doctor was in danger of being mobbed, until six clergymen came forward in his support, and the practice approved itself. In 1721 and 1722 he inoculated 247 persons; 39 were inoculated by others; of the whole number only 6 died. During the same period, of 5,759 who had the disease in the natural way, 844 died.

BOYNE, a river of Ireland, which rises near Carberry in the barony of that name, county of Kildare. It is formed by the confluence of several small streams, and after leaving the bog of Allen has a N. E. course to the town of Navan, where it is joined by the Blackwater. After this it flows nearly E. to Drogheda, on its left bank, and 4 m. below that city falls into the Irish channel about 10 m. S. of Dunany point, the headland of Dundalk bay, after a winding course of 60 m. from its source. It is navigable 25 m. from the sea. It has been called the "Boyne of science" on account of the many monastic institutions along its shores, and is celebrated for its scenery, and for its ancient and modern historical associations. The decisive battle between William III. and James II. was fought on the banks of the Boyne, July 12, 1690. An obelisk, erected in 1736, opposite the ford at Oldbridge, marks the spot where William was wounded.

BOYSE, Boys, or Bois, John, an English theologian, born at Nettlehead, Suffolk, Jan. 3, 1560, died Jan. 14, 1643. He was one of the translators of the Bible appointed by James I., and not only executed his own task, which was the Apocrypha, but also that of one of the others. He was also one of the six revisers of the whole. He afterward assisted Sir Henry Savile in his edition of St. Chrysostom. Andrews, bishop of Ely, made him prebendary of his cathedral in 1615. He left many MSS. At his death, one of which, on the text of the Evangelists and the Acts, was published in 1655. Peck's *Desiderata* (2 vols. fol., London, 1732-'5) contains his curious autobiography.

BOZMAN, John Leeds, an American historian and jurist, born at Oxford, Talbot co., Md., Aug. 25, 1757, died there, April 23, 1823. He

graduated at the university of Pennsylvania in 1788, studied law in London, and afterward practised in his native state, where for several years he was deputy attorney general. He wrote a "Historical and Philosophical Sketch of the Prime Causes of the Revolutionary War," in which he praised Washington and depreciated Franklin; but it was suppressed. During the administrations of Washington and John Adams he wrote much in prose and verse for the press, and at a later period contributed to Dennie's "Port Folio." His principal work is his "History of Maryland, from the earliest Settlement in 1633 to the Restoration in 1660," the introduction published in 1811, and the complete work in 1837 (2 vols., Baltimore), under the auspices of the state.

BOZRAH, or **Bostra**, a ruined city of Syria, in an oasis on the S. E. border of the Hauran, 76 m. S. S. E. of Damascus, in lat. 32° 30' N., lon. 36° 24' E. It was one of the chief cities of Bashan, and is about 5 m. in circuit, with

tween the Bozrah mentioned as a town of Edom and the Bozrah of Moab, identifying the latter with the Bostra of the ancients, and the former with Busaireh between the Dead sea and Petra; while still others contend that none of the Scriptural Bozrahs correspond to the Bostra of Bashan. This city was enlarged and embellished by the Romans, and in the reign of Trajan it was made the capital of the province of Arabia and received the name of Nova Trajana Bostra. Under the emperor Philip it was the seat of a bishop, and afterward of an archbishop. On the invasion of the Saracens it began to fall into decay, and in the reign of Baldwin IV. of Jerusalem (1180) it was ravaged by the Turks.

BOZZARIS, **Marco** (**MARCOS BOTZARIS**), a Greek patriot, born about 1790, died near Missolonghi, Aug. 20, 1823. His father, Kitzos Bozzaris, his grandfather, uncles, and brothers, were all distinguished patriots and warriors. In 1803, after the fall of Suli, he escaped to the Ionian islands, where he united with other refugees against Turkey. When the treaty of Tilsit restored the Ionian islands to the French, and deprived the Greeks of any hopes of immediate deliverance, he entered the French service as a sergeant in an Albanian regiment, in which his father and uncle served as majors. In 1818 he became a member of the *Hetaïria*, the great central society of the patriots. When in 1820 Ali Pasha took arms against the Porte, Bozzaris with several hundred followers joined him

Ruins of Bozrah.

high walls 15 ft. thick, and a strong castle. Among its ruins are temples, churches, mosques, baths, fountains, aqueducts, and triumphal arches. A straight street intersects the city lengthwise, and has a beautiful gate at each end; and other straight streets cross it. This city anciently contained 100,000 inhabitants; now there are scarcely 20 families. The castle stands on the S. side of the city; its outer walls and towers are still in good preservation. In the centre of this structure, supported on massive piers and arches, are the remains of a theatre 270 ft. in diameter. This fortress is supposed to have been built by the emperor Philip, who was a native of the city.—The town, which the Greeks and Romans called Bostra, is supposed by some Biblical critics, and among them Gesenius, to be identical with the Bozrah of Genesis and the prophets; but others, like Porter, distinguish be-

in Epirus, having first obtained from him the restoration of the Suli mountains. When in 1821 the insurrection against Turkey became general, Bozzaris fought in western Hellas, with varying success. In 1822 he lost the flower of his comrades in a desperate effort to relieve the Suliote stronghold of Kiapha, but continued bravely fighting, until the battle of Peta (July 16) destroyed the *élite* of the patriots. He then threw himself, with a number of Suliotes, into Missolonghi, and was one of its foremost defenders till the end of the campaign. On the reorganization of the national forces in 1823 he was appointed a general in the army of western Hellas. In the night of Aug. 19 he made with Tzavelas and others a combined night attack on the camp of the pasha of Scutari, who was advancing toward Missolonghi at the head of a considerable army. Marco, with 350 Suliotes, fought his way into

the midst of the camp, near Carpenisi, but was killed by a shot in the face while spreading carnage around him. He was borne from the battlefield, after the victory, on the shoulders of a relative, and buried in Missolonghi. The victory, however, which was signal, was not followed up. Marco was no less remarkable for modesty than for patriotism and bravery. His heroism has been commemorated, among others, by Fitz-Greene Halleck, whose poem has been translated into modern Greek.—The only son of Marco, DEMETRIUS BOZZARIS, has been minister of war under various administrations of the Greek government.

BRA, a town of Piedmont, Italy, province of Coni, in the valley and 2 m. N. of the Stura, and 9 m. W. of Alba; pop. about 12,000. It contains the celebrated church of Santa Chiara, built by Vettone in 1742. The environs produce silk of excellent quality, and there is also an active trade in wine, grain, and cattle.

BRABANT. **I. Duchy of**, one of the ancient divisions of the Netherlands, bounded N. by Holland and Gelderland, E. by Limburg and Liège, S. by Namur and Hainaut, and W. by Flanders and Zealand. The Menapii and Tungri were the original inhabitants of this country. By the Romans it was made part of the province of Gallia Belgica. The Franks settled in it in the 5th century. It successively formed part of Austrasia, of the Carolingian kingdom, of the kingdom of Lorraine, and of the duchy of Lower Lorraine. When Duke Otho died childless in 1005, Godfrey, count of Ardennes, became count of Brabant; and in 1190 Brabant was made a duchy. In 1349 Duke John III. received from the emperor the golden bull of Brabant, according to which no Brabançon could appeal to a higher court of judgment than that of the duke of Brabant. Duke John's eldest daughter, Joanna, bequeathed the duchy to her nephew, Anthony, second son of Philip the Bold, duke of Burgundy (1405). Duke Anthony fell on the French side, at the battle of Agincourt. With Philip, the younger brother of Anthony, the line of dukes terminated. Brabant passed to Philip the Good, duke of Burgundy (1430), and remained an integral part of the duchy of Burgundy until, in 1477, Maximilian, the future emperor of Germany, married Mary, the heiress of Charles the Bold of Burgundy. Brabant then passed under the dominion of the house of Austria. The emperor Charles V. left it to his son Philip II. of Spain. In the revolt of the Netherlands Brabant was among the first to join, but was not successful in its efforts. At the peace of Westphalia (1648) the northern part was abandoned to the United Provinces, and received the name of North Brabant; at the same time the provinces of Antwerp and Mechlin were cut off from the ancient limits of the duchy, and erected into separate territories under Spanish rule. The remaining part was called thenceforth South Brabant, and remained a part of

the hereditary possessions of the Spanish crown until the war of Spanish succession, at the end of which it reverted to Charles VI., afterward emperor of Germany, together with Antwerp and Mechlin, and was thenceforward known as part of the Austrian Netherlands. Both Brabants were conquered by the French in 1794. Under them North Brabant formed the department of Bouches-du-Rhin, and South Brabant the department of La Dyle and a part of Deux-Nèthes. At the congress of Vienna (1814) both Brabants were given to the king of Holland. In the revolution of 1830, South Brabant joined the revolt of the provinces which had formerly been the Austrian Netherlands, and it has since formed part of the kingdom of Belgium, while North Brabant remains part of the kingdom of Holland. **II. North**, a province of Holland, bounded N. by the provinces of Holland and Gelderland, E. by Limburg, S. by Limburg and Antwerp, and W. by Zealand; area, 1,980 sq. m.; pop. in 1870, 440,302. It is divided into the arrondissements of Bois-le-Duc, Breda, and Eindhoven; capital, Bois-le-Duc. The principal rivers are the Maas, the Dommel, the Dintel, the Donge, and the two rivers Aa. There are numerous canals. Agriculture is in an advanced condition. Mutton, poultry, bees, game, and fish are abundant. Pine is the principal tree; of minerals the country is entirely destitute. The linen, cotton, cutlery, and porcelain manufactures are highly prosperous; and the inhabitants, chiefly Roman Catholics, are distinguished for their industry and frugality. **III. South**, the metropolitan province of Belgium, bounded N. by Antwerp, E. by Limburg and Liège, S. by Namur and Hainaut, and W. by East Flanders; area, 1,268 sq. m.; pop. in 1869, 862,982. It is divided into the arrondissements of Brussels, Louvain, and Nivelles; capital, Brussels. A part of the inhabitants speak Flemish and others Walloon; the great majority are Roman Catholics. The soil is flat, and in some places wooded. It is watered by the Dyle, the Dender, and the Senne. The climate is rather moist, but healthy. The agriculture is of the first quality, the land being cultivated like a garden. The products are rye, wheat, oil seed, and buckwheat, but little fruit. Cattle are reared, mostly oxen and horses; so are bees. Its manufactures are of woollen and cotton stuffs, linen, Brussels lace, leather, hats, playing cards, tobacco, starch, brandy, paper, and oil. South Brabant is intersected by several railroads and canals.

BRACCIOLINI. See Poggio.

BRACE, Charles Loring, an American clergyman and author, born at Litchfield, Conn., in 1826. He graduated at Yale college in 1846, and afterward studied theology in the theological department of that institution, and at the Union theological seminary, New York. He has since been a recognized preacher, but has not been connected with any church. In 1850 he made a pedestrian journey in Great Britain

and Ireland, also visiting the Rhine, Belgium, and Paris. An account of part of this journey was afterward published by his companion, Mr. Frederick Law Olmsted, under the title of "Walks and Talks of an American Farmer in England." In the following year he visited Hungary, where he was arrested on suspicion of being a secret agent of Kossuth, and tried before a court martial, but, through the efforts of O. J. McCurdy, United States chargé d'affaires at Vienna, was soon released. He afterward visited Switzerland, England, and Ireland, giving special attention to schools, prisons, and reformatory institutions. Returning to the United States in 1852, he became associated in the labors of the Rev. Mr. Pease among the most degraded class of the city of New York, and was chiefly instrumental in the formation of the "Children's Aid Society," an association for transferring destitute and vagrant children to homes in the country, and which also to a large extent provides lodgings, instruction, and other aid for poor boys and girls in the city. Of this society he is still (1873) the secretary and principal agent. In 1856 he made a journey in northern Europe, and in 1872 revisited Hungary, where he was received with marked attention. He has published "Hungary in 1851" (1852); "Home Life in Germany" (1853); "Norse Folk," a description of the religious, social, and political condition of the people of Sweden and Norway (1857); "Races of the Old World" (1863); "The New West" (1869); "Short Sermons for Newsboys;" and "The Dangerous Classes of New York" (1872).

BRACE, Julia, a blind deaf mute, born at Newington, Conn., in 1806. She lost both sight and hearing at the age of 4½ years, and soon forgot the few words she had learned to speak. In 1825 she entered the American asylum for the deaf and dumb at Hartford, and remained there about 30 years, when she went to Bloomfield, Conn., where she still resides with a sister (1873). As compared with other blind deaf mutes, she seems possessed of only ordinary abilities. In all that concerns outward and material nature she manifests much intelligence. She possesses great tenacity of memory and nice powers of discrimination, being able to distinguish readily articles belonging to different persons. She keeps herself apprised of the progress of time, days, weeks, and months, and notes the return of the Sabbath. In her intellectual education she has made little progress; a few facts have been acquired, but soon forgotten. It is doubtful if she possesses any distinct idea of God, but she seems to have a sense of right and wrong. She has never been guilty of theft, falsehood, or any deliberate wickedness; and while tenacious of her own rights, she will not knowingly invade those of others.

BRACHIOPODA, or **Brachiopods** (Gr. *βραχιον*, arm, and *πους*, foot), till within a few years universally regarded as one of the classes of

mollusca, named by Cuvier from two long, ciliated arms, which project from the side of the mouth, and with which they create currents that bring them food. By De Blainville and Owen they were called *palliobranchiata*, from *pallium*, a mantle, and *branchia*, gills, the delicate mantle covering the body constituting the respiratory apparatus of the animals. They are bivalve, differing from the conchifera in the valves being always unequal; yet they are symmetrical and equal-sided. The valves are dorsal and ventral, instead of right and left, the smaller and lower being generally considered the dorsal valve. By the old naturalists they were commonly called *lampades*, or "lamp shells," from the resemblance of their form to that of the antique lamps; the hole for the wick in these being represented in the shell by the curved beak of the ventral valve, through which the organ passes by which the animal attaches itself to any substance. The brachiopoda all belong to salt water. They are found attached to corals, to other

Arms of Brachiopod.

shells, and to the under sides of shelving rocks. Though a low animal type, no other class exhibits such a great range in time, geographical distribution, and depth of water; they are found from the Silurian to the present epoch, from the poles to the tropics, and from near high-water mark to the greatest depths reached by the dredge. Among the earliest forms of animal life were the *lingula* of the lowest fossiliferous rocks. This genus has continued through all the series of formations, during which multitudes of other forms have been introduced and spread through an immense number of species, which have long since disappeared, leaving no type of their family in existence; but the ancient genus *lingula* is still met with in the Pacific and on our Atlantic coast; and the *terebratula* and *discina*, which were introduced in periods nearly as remote, have representatives living in many parts of the world. More than 1,000 extinct species have been described. They constitute a large proportion of the shells found so abundantly throughout the New York system, as the *spirifer*, *productus*, *atrypa*, *strophomena*, &c. They were most numerous in the Silurian and Devonian epochs, since which they have been declining; there were about 700 in the palæozoic age, not more than 200 in the cretaceous period, and there are fewer than 100 at the present time, of which the best known genera are *lingula*, *terebratula*, *discina*, *rhynchonella*, and *crania*, all of which are very old forms.—Naturalists have for some

Terebratula septentrionalis.

years been of the opinion that the brachiopods and polyzoa form a natural anatomical class, defined by Prof. Hyatt as a sac closed at one end by a disk, surrounded by free tentacles, and perforated by a toothless mouth from which hangs the alimentary canal. Some recently have been inclined to add the ascidians, and to separate the three from the mollusca, under the name of *molluscoida*; the ascidians seem to form the connecting link of the molluscoids with the bivalve mollusks; the first two agree in having but one aperture to the atrial chamber, and a complicated muscular system intersecting the visceral cavities. Prof. E. S. Morse, in "Memoirs of the Boston Society of Natural History," 1871, from the study since 1869 of *terebratulina* and *discina*, in all stages of growth, finds the following articulate characters, which induce him to remove the brachiopods from mollusks: the shell is like that of crustacea in its tubular structure, scale-like appearance, and chemical composition; in *lingula* there is 42 per cent. of phosphate of lime, and only 6 per cent. of carbonate of lime; the horny bristles or setæ fringing the mouth are remarkably worm-like; they are secreted by

Lingula anatina.

follicles, surrounded by muscular fibres, and freely movable. Gratiolet has compared the circulatory system with that of crustacea, and Burmeister has shown the resemblance between the respiratory apparatus of *lingula* and that of certain cirripeds. The oviducts resemble the similar organs in worms in their trumpet-shaped openings; the part bearing the cirri, and the mantle covering the arms, are comparable to similar parts in tubicolous worms. From French and German authors we have many proofs of their affinity with the worms in embryological characters. These views were confirmed by Prof. Morse's study of the living *lingula* on the coast of North Carolina, near Fort Macon. Here he ascertained that they make a tube in the sand, like annelids; the peduncle is hollow, distinctly ringed, with longitudinal and circular fibres, very contractile, and remarkably worm-like; they have also red blood, and the sexes are distinct. His conclusions are that they are "true articulates, having certain affinities with the crustacea, but properly belonging to the worms, coming nearest the tubicolous annelids: they may be better regarded as forming a comprehensive type, with general articulated features." Possibly they have affinities with the mollusks, as homologies have been pointed out between the polyzoa and tunicates or ascidians.

BRACKEN, a N. E. county of Kentucky, bordering on the Ohio river and drained by the north fork of Licking river; area, 200 sq. m.;

pop. in 1870, 11,409, of whom 636 were colored. The soil is generally fertile and productive. The chief productions in 1870 were 20,-229 bushels of wheat, 20,610 of rye, 440,530 of Indian corn, 22,533 of oats, and 4,188,039 lbs. of tobacco. There were 8,760 horses, 2,087 milch cows, 2,311 other cattle, 3,445 sheep, and 12,719 swine. Capital, Augusta.

BRACKENRIDGE, **I. Hugh Henry**, an American judge and author, born near Campbellton, Scotland, in 1748, died at Carlisle, Penn., in 1816. In 1771 he graduated at Princeton college, where he subsequently acted as tutor. Having studied divinity, he became a chaplain in the continental army; but he soon relinquished the pulpit for the bar, and edited for a time the "United States Magazine" at Philadelphia. In 1781 he established himself at Pittsburgh, and in 1799 was appointed a judge of the supreme court of the state, which office he held till his death. He participated with Gallatin in the whiskey insurrection, and vindicated his course in the "Incidents of the Insurrection in Western Pennsylvania, in 1794," published in 1795. His "Modern Chivalry, or the Adventures of Captain Farrago," a humorous and political satire, has been especially popular throughout the West. The first portion was published at Pittsburgh in 1796, and was republished in Philadelphia in 1846, with illustrations by Darley. The second portion was published 10 years after the first; and both were issued together in 1819. He also wrote many miscellaneous essays and fugitive verses.

II. Henry M., an American lawyer, diplomatist, and author, son of the preceding, born in Pittsburgh, Penn., May 11, 1786, died there, Jan. 18, 1871. At 20 years of age, having been admitted to the bar, he commenced practice in Somerset, Maryland. In 1811 he was appointed deputy attorney general for the territory of Orleans, afterward the state of Louisiana, and the next year was made district judge. During the war of 1812 he gave the government valuable information, and afterward wrote a history of the war, which was translated into French and Italian. He joined with Mr. Olney in advocating the acknowledgment of the independence of the South American republics. His pamphlet under the name of "An American," addressed to President Monroe, was republished in England and France, and, being supposed to express the views of the American government, was replied to by the duke of San Carlos, the Spanish minister. He was appointed one of the commissioners to the South American republics in 1817, and on his return published his "Voyage to South America," which was said by Humboldt to contain an "extraordinary mass of information." He accompanied Gen. Jackson to Florida in 1821, and in May was appointed judge of the western district, in which office he remained for 10 years. He removed to Pittsburgh in 1832, was elected to congress in 1840, and the year after was named a commissioner under the treaty with Mexico. His

political writings are numerous. In 1859 he published a "History of the Western Insurrection," in vindication of his father.

BRACKETT, I. Edwin E., an American sculptor, born in Vassalborough, Me., Oct. 1, 1819. He has produced portrait busts of Washington Allston, Richard Henry Dana, Bryant, Longfellow, Rufus Choate, Sumner, John Brown, Garrison, Wendell Phillips, Gen. Butler, and others, and a marble group of the "Shipwrecked Mother," now at the cemetery of Mount Auburn, near Boston. **II. Walter M.**, a painter, brother of the preceding, born in Unity, Me., June 14, 1823. He is known chiefly as a painter of salmon, trout, and other varieties of game fish.

BRACTON, Henry de, lord chief justice of England in the time of Henry III., died about 1270. He was educated and took the degree of doctor of laws at Oxford, and about 1244 was made one of the itinerant judges. Ten years later he became chief justice, and held the office 20 years. He wrote *De Legibus et Consuetudinibus Angliæ*, one of the earliest English law books (fol., 1569).

BRADBURN, Samuel, an English clergyman, born at Gibraltar, where his father was stationed with his regiment, Oct. 5, 1751, died July 24, 1815. His parents removed to Chester, England, and he was apprenticed to a shoemaker; but he became a Wesleyan local preacher in 1773, and entered the itinerant ministry in 1774. He shared the troubles of the early Methodist preachers, but his adroit humor and his persuasive eloquence often conquered opposition and made him popular. He was the great natural pulpit orator of Wesleyan Methodism; combining a nobility of person, a scrupulous neatness of apparel, a ready wit, and a genuine pathos, that drew to him multitudes of hearers. In 1799 he was elected president of the Wesleyan conference. His "Sermons on Particular Occasions" (1 vol. 12mo) appeared in 1817.

BRADDOCK, Edward, a British general, born in Perthshire about 1695, died near Pittsburgh, Penn., July 13, 1755. Having served with distinction in Spain, Portugal, and Germany, he was in 1755 sent to take charge of the war against the French in America. He set out soon after his arrival on an expedition against Fort Duquesne (now Pittsburgh). Although unacquainted with Indian warfare, he disregarded the suggestions of Col. Washington, acting as his aide-camp, fell into an ambush of French and Indians near that fort, July 9, 1755, was defeated and mortally wounded, and died after a hasty retreat of 40 miles.

BRADDON, Mary Elizabeth, an English novelist, born in London in 1837. Her father, Mr. Henry Braddon, a solicitor, contributed to sporting papers, and she early exhibited literary talent. In 1860 her comedietta, "The Lover of Arcadia," was performed at the Strand theatre, and in 1861 she published "Garibaldi and other Poems," and a series of tales in the "Temple Bar" and "St. James's" magazines. In 1862

her novel, "Lady Audley's Secret," secured for her a wide reputation, which has been increased by "Aurora Floyd," "Sir Jasper's Tenants," "Only a Clod," and many other sensational and attractive novels, the most recent of which, "To the Bitter End," appeared in 1872. Miss Braddon edits the "Belgravia" magazine.

BRADFORD, I. A N. E. county of Pennsylvania, bordering on New York; area, 1,170 sq. m.; pop. in 1870, 53,204. The Elmira and Williamsport and the Lehigh Valley railroads pass through the county, and there are railroads to the coal mines S. and S. W. from Towanda. It is intersected by the North branch of the Susquehanna, and drained by Towanda, Wyalusing, and Sugar creeks, which afford good water power. The surface is uneven and thickly wooded with pine, hemlock, and sugar maple. The soil is good. Iron, bituminous coal, and sandstone are abundant, but lumber is the principal article of export. The chief productions in 1870 were 285,698 bushels of wheat, 33,991 of rye, 505,841 of Indian corn, 1,114,120 of oats, 382,581 of buckwheat, 541,198 of potatoes, 129,956 tons of hay, 3,704,709 lbs. of butter, and 122,258 of wool. There were 12,131 horses, 35,243 milch cows, 27,275 other cattle, 36,257 sheep, and 12,000 swine. Capital, Towanda.

II. A N. E. county of Florida, bounded S. W. by the Santa Fé river; area, 940 sq. m.; pop. in 1870, 3,671, of whom 824 were colored. The Florida railroad passes through the S. E. part. The chief productions in 1870 were 45,708 bushels of Indian corn, 6,170 of oats, 13,273 of sweet potatoes, 295 bales of cotton, 3,096 lbs. of wool, 49 hhd. of sugar, and 8,518 gallons of molasses. There were 375 horses, 2,843 milch cows, 5,763 other cattle, 1,833 sheep, and 4,816 swine. Capital, Lake Butler.

BRADFORD, a market town and parliamentary borough of the West Riding of Yorkshire, England, on an affluent of the Aire, 8 m. W. of Leeds and 29 m. S. W. of York; pop. in 1871,

Bradford Town Hall.

145,827. In its vicinity are the celebrated iron works of Low Moor and Bowling. Bradford is the principal seat of the English worsted

manufacture, both in yarn and in piece. There are also numerous cotton mills, foundries, and manufactories of combs and machinery. A custom house and inland bonding warehouse have been established here. A handsome and commodious town hall was commenced in 1870, to cost £74,000, including £30,000 for land. The town is situated at the union of three extensive valleys, surrounded by picturesque scenery, and has the advantage of many ancient and excellent schools. The Airedale college, for the education of Independent ministers, is at Undercliffe, near Bradford, and a Wesleyan seminary for ministers' sons at Woodhouse Grove.

BRADFORD, Alden, an American author, born at Duxbury, Mass., in 1765, died in Boston, Oct. 26, 1848. He was descended from Gov. Bradford, graduated at Harvard college in 1786, and was settled as pastor of a Congregational church at Wiscasset, Maine, for eight years. He afterward engaged in the book trade in Boston, and from 1812 to 1824 was secretary of state of Massachusetts. He published a history of Massachusetts from 1764 to 1820, a "History of the Federal Government," and many miscellaneous pieces at different times.

BRADFORD, John, an English martyr, born at Manchester about 1510, burnt at Smithfield after a long imprisonment, July 1, 1555. He was appointed chaplain to Edward VI. in 1552, and became one of the most popular preachers in the kingdom. In the reign of Mary he was tried on a charge of sedition and heresy, and sentenced to death. The Parker society published his theological treatises in 1848.

BRADFORD, William, second governor of Plymouth colony, born in Yorkshire, England, in March, 1588, died May 9, 1657. At an early age he emigrated to Holland for the sake of religious liberty, and, having joined the English congregation at Leyden, sailed for America in 1620, in the Mayflower. Upon the death of Gov. Carver in 1621, he was elected to supply his place. One of his first acts was to adopt measures to confirm the league with Massasoit, who afterward disclosed to the colony a dangerous conspiracy among the Indians, which was suppressed. The first legal patent or charter of the colony was obtained in the name of John Pierce; but in 1630 a more comprehensive one was issued in the name of William Bradford, his heirs, associates, and assigns. In 1640 the general court requested him to deliver the patent into their hands, and upon his complying immediately returned it into his custody. He was annually elected governor as long as he lived, excepting five years at different intervals, when he declined an election, holding the office 31 years. Though without a learned education, he wrote a history of Plymouth colony from 1602 to 1647. On the retreat of the British army in 1775, the MS. was carried away from the library of the Old South church in Boston, but was recovered and printed entire by the Massachusetts historical society in 1856. A large

book of copies of letters relating to the affairs of the colony was also lost; but a fragment of it found in a grocer's shop at Halifax has been printed by the same society.

BRADFORD, L. William, the first printer in Pennsylvania, born in Leicester, England, in 1658, died in New York, May 23, 1752. Being a Quaker, he emigrated in 1682, and landed where Philadelphia was afterward built. In 1686 he printed an almanac. In 1692, having printed the alleged seditious writings of George Keith, he was tried for libel. The justice having charged the jury to find only the fact as to the printing, Bradford maintained that they were to find also whether the paper was really seditious, and that "the jury are judges in law as well as the matter of fact." He was not convicted, but having incurred the displeasure of the dominant party in Philadelphia, he removed to New York in 1693, and in that year printed the laws of the colony. On Oct. 16, 1725, he began the first newspaper in New York, called the "New York Gazette." In 1728 he established a paper mill at Elizabethtown, N. J. For more than 50 years he was printer to the government of New York, and for 30 years the only one in the province. **II.**

Andrew, an American printer, son of the preceding, born in Philadelphia about 1686, died Nov. 23, 1742. He was the only printer in Pennsylvania from 1712 to 1723. On Dec. 22, 1719, he commenced the "American Weekly Mercury," the first newspaper in Philadelphia; and he gave employment to Benjamin Franklin on his arrival there in 1723. In 1732 he was postmaster. In 1735 he kept a bookstore at the sign of the Bible in Second street; and in 1738 he removed to No. 8 South Front street, to a house which in 1810 was occupied as a printing house by his descendant, Thomas Bradford, publisher of the "True American."

BRADFORD, William, an American lawyer, born in Philadelphia, Sept. 14, 1755, died Aug. 28, 1795. He graduated at Princeton college in 1772, and was admitted to the bar in 1779. In 1776 he joined the militia, and attained the rank of lieutenant colonel; but in consequence of ill health he resigned at the end of two years. In 1780 he was appointed attorney general of Pennsylvania, a judge of the supreme court in 1791, and attorney general of the United States, Jan. 28, 1794. In early life he wrote some pastoral poems in imitation of Shenstone; but his principal production was an "Inquiry how far the Punishment of Death is necessary in Pennsylvania."

BRADFORD, William, an American painter, born in New Bedford, Mass., about 1830. He is of Quaker extraction, and was educated for commerce; but failing in business, he took up painting, and soon acquired facility in making portraits of ships. He practised marine painting for several years at Fairhaven, Mass., and thence made excursions along the New England coast, and northward as far as Greenland, in quest of subjects. His works relate ex-

clusively to the sea and the seashore, and he is an unusually careful delineator of shipping in every form familiar to the coast of North America. Some of his largest and most elaborate compositions have been suggested by his voyages to the higher latitudes. Of these "The Coast of Labrador" and "Crushed by Icebergs" are conspicuous examples. Other characteristic works by him are "The Island of Grand Menan," "Fishing Boats getting under Way," "Fishing Boats at Anchor," "Shipwreck off Nantucket," "Sudden Squall in the Bay of Fundy," and "A Stiff Breeze in the Harbor of Eastport." Many of these have been photographed. He is now (1873) practising his profession in New York.

BRADLEY, I. A. S. county of Arkansas, bounded W. by Moro bayou and traversed by Saline river; area, 958 sq. m.; pop. in 1870, 8,646, of whom 2,529 were colored. The surface is generally level. The chief productions in 1870 were 4,726 bushels of wheat, 222,825 of Indian corn, 48,356 of sweet potatoes, and 5,177 bales of cotton. There were 1,656 horses, 3,536 milch cows, 5,550 other cattle, 2,544 sheep, and 16,213 swine. Capital, Warren.

II. A. S. E. county of Tennessee, bordering on Georgia and bounded N. E. by Hiawassee river; area, about 400 sq. m.; pop. in 1870, 11,652, of whom 1,700 were colored. The East Tennessee, Virginia, and Georgia railroad, and the Dalton branch of the same, pass through it. The county is well watered. The surface is uneven, and in the south mountainous, with extensive forests. The chief productions in 1870 were 112,341 bushels of wheat, 289,490 of Indian corn, 41,727 of oats, 12,810 of sweet potatoes, and 135,976 lbs. of butter. There were 2,181 horses, 2,455 milch cows, 3,497 other cattle, 9,146 sheep, and 13,633 swine. Capital, Cleveland.

BRADLEY, James, an English astronomer, born at Sherborne, Gloucestershire, in March, 1692, died at Chalford, July 13, 1762. He was educated at Oxford and took orders, but devoted himself wholly to the study of astronomy. He was chosen a fellow of the royal society in 1718, and three years afterward was appointed Savilian professor of astronomy at Oxford. In 1727 he published his brilliant discovery of the aberration of light, and in 1747 the equally valuable discovery of the nutation of the earth's axis. He also made successful researches into the law of refraction, for which he produced an empirical formula. In 1742 he succeeded Dr. Halley as astronomer royal, and in 1751 he received a pension in consideration of the "advantages of his astronomical labors to the commerce and navigation of Great Britain." From his valuable observations, published after his death, Meyer formed his table of the moon, and Bessel drew the elements of his *Fundamenta Astronomiæ*.

BRADSHAW, John, president of the court which tried Charles I., born about 1590, died in 1659. He was made chief justice of Chester in

1647, and sergeant in 1648; and on Jan. 10, 1649, the commissioners for trying the king chose him for their president. He performed the duties of the office with dignity and sternness, and declared on his deathbed that if the king were to be tried and condemned again, he would be the first to agree to it. He was made chancellor of the duchy of Lancaster and lord president of the council of state, and received valuable grants from parliament. He opposed Cromwell's elevation to the supreme power, and on the latter's assumption of the protectorate, he was accordingly deprived of the chief justiceship of Chester; but after Cromwell's death he obtained a seat in the council, and was again elected president. Bradshaw left the reputation of a cold and impassive, but upright, conscientious, and heroic republican. He was buried with great pomp in Westminster abbey, but on the restoration his body was taken from the tomb and gibbeted beside those of Cromwell and Ireton.

BRADSTREET, Anne, an American poetess, born in Northampton, England, about 1612, died Sept. 16, 1672. She was the daughter of Gov. Thomas Dudley, and in 1628 married Simon Bradstreet, afterward governor of Massachusetts, with whom she emigrated to New England in 1630. Her poems were published in London in 1650. The volume was entitled "The Tenth Muse, lately sprung up in America," and contained, according to the title page, "a complete Discourse and Description of the Four Elements, Constitutions, Ages of Men, Seasons of the Year, together with an Exact Epitome of the Four Monarchies, viz., the Assyrian, Persian, Grecian, Roman." There was also a dialogue on politics, &c., between Old and New England, "with divers other pleasant and serious Poems." Her verses are distinguished by a great amount of curious and exact learning, especially in natural history, set forth with singular quaintness, and in the most literal manner. A second edition, published at Boston in 1678, contains her "Contemplations," a poem much superior to her other works. Mrs. Bradstreet was the mother of eight children, to whom she alluded in some verses containing these familiar lines:

I had eight birds hatch't in the nest;
Four cocks there were, and hens the rest.
I nurs't them up with pains and care,
For cost nor labor did I spare;
Till at the last they felt their wing,
Mounted the trees, and learned to sing.

A third edition of her "Tenth Muse" appeared in 1758; and her complete works, both prose and verse, edited by the Rev. G. E. Ellis, D. D., were published at Charlestown in 1868.

BRADSTREET, John, an English general, born in 1711, died in New York, Sept. 25, 1774. When a young officer he was ordered to join the British forces in America, and spent the remainder of his life there. He took part in the expedition against Louisburg in 1745, as lieutenant colonel of a colonial regiment, and was in the same year made a captain in the

regular line. In 1746 he was made governor of St. John's, Newfoundland. In 1755 he was ordered to Oswego by Gen. Braddock, and acted as adjutant general to Gov. Shirley. In 1756, while carrying supplies, he was attacked by the enemy in force, but defeated them. He became lieutenant colonel and deputy quartermaster general in 1757, took part in the attack on Ticonderoga in 1758, and soon after was made colonel and quartermaster general. In the same year he led an expedition against Fort Frontenac, and captured it by surprise. He served under Amherst in his expedition against Ticonderoga and Crown Point in 1759, marched against the Indian tribes in the west and made a treaty with them at Detroit in 1764, and was made a major general in 1772.

BRADSTREET, Simon, governor of Massachusetts, born in Lincolnshire, England, in 1603, died at Salem, Mass., March 27, 1697. He was steward to the countess of Warwick, married Anne, daughter of Thomas Dudley, and engaged in the enterprise of founding a colony in Massachusetts. In March, 1630, he was chosen assistant judge, and arrived at Salem in the course of the summer. He became secretary, agent, and commissioner of the united colonies, and in 1662 was despatched to congratulate Charles II. on his restoration, and look after their interests. He was assistant from 1630 to 1679, and from 1678 to 1679 deputy governor; then governor till 1686, when the charter was annulled. When Andros was imprisoned in April, 1689, he was restored to the office, which he held till the arrival of Sir William Phipps in 1692, with the new charter, when he became first council. He was in public service 62 years, except during the brief administrations of Joseph Dudley and Andros.

BRADSTREET, Simon, minister at Charlestown, Mass., born in 1669, died Dec. 31, 1741. He graduated at Harvard college in 1693, and attained a high rank as a preacher and a scholar. He was so subject to hypochondria as to be afraid to preach from the pulpit, but spoke from the deacon's seat, without notes, usually upon the vanity of earthly things.

BRADWARDIN, Bredewardine, or Bredwardine, Thomas, an English scholar and theologian, called "the profound doctor," died Aug. 26, 1349. He was a proctor at Oxford in 1325, and ultimately its chancellor, and afterward chaplain of the bishop of Durham, chancellor of the diocese of London, prebendary of Lincoln, chaplain to Edward III., and in 1349 archbishop of Canterbury. He was consecrated at Avignon in France, being at the time with the king in that country, and hastened to England to enter upon his duties, but died of the plague before his enthronement at Canterbury. He was especially distinguished as a mathematician, and wrote several works on geometry, arithmetic, and the higher mathematics. But his principal work was his essay *De Causa Dei*, in which, according to some writers, he advanced doctrines nearly approaching those of the mod-

ern Protestants. A folio edition of this, edited by Sir Henry Savile, appeared in London in 1618.

BRADY, James Topham, an American lawyer, born in New York city, April 9, 1815, died there, Feb. 9, 1869. His father emigrated from Ireland in 1812, and after teaching a classical school for some years became a lawyer and finally a judge. He educated his son himself, and at the age of 16 James had acquired sufficient knowledge of law to act as junior counsel to his father. He was admitted to the bar at the age of 20, and soon became distinguished for ability, legal learning, and eloquence. He was often intrusted with great civil cases, which he managed generally with success. But it was as a criminal lawyer that he gained the highest reputation. In a single week he defended four clients charged with murder, all of whom were acquitted. Of the 52 capital cases in which he was counsel, in only one was he unsuccessful, and in that his client was tried as a spy and a guerilla before a court martial. In politics he was a zealous democrat, but he declined to accept any office but that of corporation counsel, which he considered a professional one. He consented in 1860, however, to be the candidate of the ultra states rights party for governor, because there was no chance of his election. During the civil war he gave a general support to President Lincoln's administration, and near the close of it he accepted an appointment as one of a commission to go to New Orleans to investigate the management of the department of the gulf under Gen. Butler and Gen. Banks. The commission made a voluminous report, which has never been published. Mr. Brady wrote much for the magazines and other periodicals, and one of his contributions, which appeared in 1846 in the "New World," entitled "A Christmas Dream," subsequently became popular as a holiday book.

BRADY, Nicholas, an English divine, born at Bandon, Ireland, Oct. 28, 1659, died at Richmond, near London, May 20, 1726. He was partly educated at Oxford, and partly at Trinity college, Dublin. In the revolution he sided with King William, who made him one of his chaplains. In 1726, just before his death, he published a poetical translation of Virgil's *Æneid*, now unknown; also a tragedy, and numerous sermons. His reputation mainly rests on a metrical version, in conjunction with Nahum Tate, of the Psalms of David.

BRAG, a game at cards, deriving its name from the efforts of the players to impose upon the judgment of their opponents by boasting of better cards than they possess. The number of players is usually from four to eight. The game is played with the entire pack of cards, which rank as at whist, except the knaves and nines. These are called "braggers," and rank the same as any cards they may be held with. Thus, an ace and two knaves or nines, or one of each, are called three aces; a deuce and two braggers, three deuces; a king and one bragger, two kings, and

so on. The best hand is a pair royal, *i. e.*, three cards of one kind, the highest being three aces; the next is the highest pair, and then the highest single card. Stakes are put up by each player, after which the cards are shown and the best hand wins.

BRAGA (anc. *Bracara Augusta*), a city of Portugal, in the province of Minho, 33 m. N. by E. of Oporto; pop. in 1864, 19,514. It is situated on an eminence between the rivers Cavado and Deste, and is surrounded by old walls and defended by a fortress. It is the archiepiscopal see of the primate of Portugal, and contains a fine Gothic cathedral, the palace of the archbishop, and a large number of fountains. In the vicinity is the remarkable pilgrimage chapel of the *Bom Jesus*, which stands on the summit of a steep hill, whence there is a magnificent view of the city and of its picturesque environs. Many articles of common use are largely manufactured here, and there are weekly markets and two important annual fairs. The town is supposed to have been founded by the Carthaginians. There are considerable remains of its Roman occupation. It was afterward the capital of the Suevi, and one of the most prominent towns in the early history of Portugal.

BRAGANÇA, or *Braganza*, a town of Portugal, capital of the province of *Tras-os-Montes*, 103 m. N. E. of Oporto; pop. in 1864, 5,101. It has the ruins of an ancient castle, one of the finest feudal remains in Portugal. It is the see of a bishop, and has some manufactories of silks and velvets. Bragança has given its name to the present royal family of Portugal.

BRAGANÇA, House of, the reigning house of Portugal, derived from Affonso, duke of Bragança, a natural son of John I., king of Portugal. The constitution of Lamego, 1189, declares that no foreign prince can succeed to the throne; consequently in 1578, on the death of King Sebastian in Africa, without issue, his people had recourse to the illegitimate line of Bragança. Philip II. of Spain, however, claimed the throne, and successfully supported his pretensions by an army under the duke of Alva. Philip and his successors on the Spanish throne continued to rule Portugal till 1640, when the Portuguese shook off the Spanish yoke and proclaimed Dom João, the then duke of Bragança, their king. He assumed the title of John IV., and the line of Bragança has continued to rule Portugal till the present time.

BRAGG, Braxton, an American general in the confederate service, born in Warren county, N. C., about 1815. He graduated at West Point in 1837, was appointed lieutenant of artillery, and served mainly in Florida till 1843, during the war with the Seminoles; from 1843 to 1845 he was stationed at Fort Moultrie, in Charleston harbor, and just before the breaking out of the war with Mexico was ordered to Texas. In May, 1846, he was made captain by brevet for gallant conduct in the defence of Fort Brown, and in June was made

captain of artillery. He was present at the battle of Monterey, Sept. 21-23, and was breveted as major for gallant conduct there; and in 1847 he was breveted as lieutenant colonel for gallant conduct in the battle of Buena Vista. From 1848 to 1855 he was engaged in frontier service at Jefferson Barracks, Mo., Fort Gibson, and Washita. In March, 1855, he was appointed major of cavalry, but declined, and received leave of absence. In January, 1856, he resigned his commission in the army, and retired to his plantation at Thibodeaux, La. In 1859-'61 he was commissioner of the board of public works of the state of Louisiana. When the civil war broke out, he joined the confederates, was appointed brigadier general, and placed in command at Pensacola. In February, 1862, he was made major general, and ordered to join the army of the Mississippi. He took part in the battle of Shiloh, April 6 and 7, was raised to the full rank of general in place of Gen. A. S. Johnston, killed at Shiloh, and after the evacuation of Corinth succeeded Gen. Beauregard in command of the department. In August he left Tennessee at the head of a strong force, and entered Kentucky, but after the battle of Perryville, Oct. 8, was forced to retreat, carrying with him a vast amount of supplies and many recruits from Kentucky. He was removed from his command and placed under arrest, but was soon restored, and resumed command of the force opposed to the federal army under Rosecrans. He was checked by Rosecrans in the protracted contest of Stone river or Murfreesboro, Dec. 26, 1862, to Jan. 2, 1863, again encountered and defeated him at Chickamanga, Sept. 19-20, 1863, but was decisively defeated by Gen. Grant at Chattanooga, Nov. 23-25. Shortly afterward he was relieved from command and called to Richmond, where for a time he acted as military adviser to President Davis, with whom he was a favorite. In the autumn of 1864 he led a small force from North Carolina to Georgia, to operate against Sherman, but without success.

BRAHAM, John, an English tenor singer, born of Jewish parents in London about 1774, died there, Feb. 17, 1856. He first appeared on the stage at the age of 12 years, and for more than half a century enjoyed a high reputation throughout Europe. In 1796 he appeared in opera at the Drury Lane theatre, after which he sang with the greatest success in Paris and the leading cities of Italy. Returning to England in 1801, he appeared in opera at Covent Garden and afterward at Drury Lane, where for more than 25 years he proved a strong attraction. In 1840 and 1841 he appeared in the United States and created great enthusiasm by his singing in operas, oratorios, and concerts. In 1841 he returned to England, and continued even to the age of 80 years to attract large audiences. He was noted for the purity of his voice and the brilliancy of his execution, and is said to have retained command of the

tenor scale longer than any other man ever known. Braham also composed numerous songs which met with great popularity, and were noted for the beauty of their melody.—His son AUGUSTUS acquired some distinction as a tenor singer. He first sang in opera in New York in 1852, having previously appeared in concerts.

BRAHE, **Tycho** or **Tyge de**, a Danish astronomer, of Swedish origin, born at Knudstorp, in Scania, which then belonged to Denmark, Dec. 4, 1546, died in Prague, Oct. 13, 1601. He came of an ancient princely family, the ruins of whose castle, Wisingsborg, are still visible on the shore of Lake Wetter. He was the second of ten children, and he as well as his youngest sister Sophia early displayed great intellectual ability. After having been under the care of private tutors, his maternal uncle, Steno Belle, sent him after the death of his father to Copenhagen to study philosophy, and in 1562 to Leipsic to study law; but astronomy engrossed his attention almost exclusively, the fulfilment of the prediction in regard to the eclipse of the sun in 1560 having essentially contributed to strengthen his faith in that science. His relatives insisting upon his preparing himself for the law and for statesmanship, he clandestinely devoted the night to astronomical observations, with the aid of a small celestial globe and a wooden circle for the measurement of the stars, thus observing in 1563 the junction of Saturn with Jupiter. The inheritance of a considerable fortune in 1565 left him at liberty to prosecute his experiments, in which he was encouraged by the Danish government in 1568. After spending some time in Augsburg, he returned to Copenhagen in 1570 with a European reputation, which was increased in 1572 by his discovery of a new star, though this did not reappear after 1574. His uncle gave him every opportunity for astronomical observations at his seat near Knudstorp; but his marriage with a peasant girl produced great unpleasantness with his relatives, though Frederick II. of Denmark endeavored to effect a reconciliation. At the king's request he lectured at Copenhagen in 1574 on the theory of comets and on mathematics, and he afterward visited Germany, Switzerland, and Italy. He resolved in 1576 to settle permanently in Basel; but the king secured his services by bestowing upon him for life the island of Hven in the Sound, and by building there for him a laboratory and a magnificent observatory, which was finished in 1580. It acquired great celebrity under the name of Uranienborg, and Brahe gave here such a powerful impetus to astronomical science, that distinguished personages of all countries visited him, including James VI. of Scotland, afterward James I. of England, while in Denmark to marry the princess Anne. Frederick II. spared no effort and no money to enlarge the scope of the astronomer's labors, and gave him a pension of 2,000 crowns and the canonry

of Roeskilde with a revenue of 1,000 crowns, besides other endowments. But soon after the king's death he lost all these advantages, owing to the hostility of Walchendorff and other members of the council of regency. Not only was he driven from Uranienborg on account of his inability to defray the expenses of the observatory, but he was also obliged to leave Copenhagen; and in 1597 he abandoned Denmark for ever. He went with his family to Rostock, and then to Holstein, where he prevailed upon Heinrich von Rantzau to recommend him to Rudolph II. of Germany. This emperor received him with great distinction, and assigned him in 1599 a pension of 3,000 florins in gold and a residence in his own chateau of Benach, near Prague, where Kepler visited him in 1600. Subsequently Brahe was installed by the emperor in an extensive mansion in Prague, which he proposed to convert into another Uranienborg, but he died too soon for the accomplishment of this purpose. He was interred in the *Theinkirche*, one of the principal churches of Prague, where a marble effigy perpetuates his memory. The emperor purchased his valuable collection of instruments, but, with the exception of one sextant, they have all been destroyed in times of war; and his famous celestial globe of brass, said to have cost 5,000 thalers, found its way back to Copenhagen after many vicissitudes, only to be burnt during the conflagration of the palace in 1720. Brahe was of a violent and hasty temper, and so superstitious that he kept about him a lunatic whose ravings he regarded as prophetic.—His system was not extensively adopted, and is considered as but a modified form of that of Ptolemy. But to Brahe belongs the merit of having been the first to lay the foundation of practical astronomy, and Kepler used his numerous and for his time wonderful observations effectively in his discoveries. Brahe's principal publications include *Calendarium Naturale Magicum* (1582), *Progymnasmata Astronomica* (2 vols., 1587-'9), *Astronomia instaurata Mechanica* (a description of his instruments, 1598), and *Epistolarum Astronomicarum* (1610). His observations were collected by his disciples in 1666 (*Historia Cælestis*, 20 vols.). His chief biographers are, in Italian, Gassendi (Paris, 1655); in German, Helfrecht (Hof, 1798); and in Danish, Pedersen (Copenhagen, 1838). See also Brewster, "Martyrs of Science" (London, 1841), and Bertrand, *Les fondateurs de l'astronomie moderne* (Paris, 1865). *

BRAHMA, **Brahman**, **Brahmanism** (also **BRAHMIN**, **BRAHMINISM**), **Brahmana**. Of this, the most important body of words in the religious history of India, the starting point is the neuter noun *bráhma* (nom. and accus. *bráhma*), which is of frequent occurrence even in the oldest parts of the Veda, as signifying "worship, offering of devotion and praise." In later developments it is used to mean holy words, songs, action, &c., and finally the sacred principle, the highest

object of religious thought and veneration, the absolute and infinite. From it comes first the masculine noun *brahmán* (nom. *brahmá*), having a twofold use: 1, an offerer of worship, devotee, priest, and hence, more specifically, the supervising and correcting priest in the intricate Hindoo ceremonial; 2 (later, and by reflection from the later sense of *bráhma*), a kind of personal incorporation of the absolute, a theosophic highest divinity, the supreme god, *Brahma*. The secondary classes of Vedic writings are full of *bráhma* (neuter) as the theme of religious contemplation; but a god *Brahma* is much more recent, and a creature of sacerdotal philosophy. The Hindoo trinity (*trímúrti*), in which he figures as creator, beside Vishnu as preserver and Siva as destroyer, was a piece of artificial system-making, having no real root in the religious consciousness of the people. *Brahma* was never actually worshipped, nor had temples built to him. Our word *brahman* or *brahmin* represents the derivative adjective *bráhma*, which, as coming from *bráhma*, signifies "dealing with worship and sacred things," or, as in part also from *brahmán*, "of priestly descent and office." This adjective begins to appear in the more recent parts of the Veda; and with the rise of a priestly caste and a hierarchy in India, it becomes the name of that caste, the dominant class in a system of religious polity which is thence called *Brahmanism*, and of which the history constitutes an essential part of that of India. (See *INDIA*.) The neuter of the same adjective, *bráhma*, is used to denote a class of writings in the religious literature of India, next in age to the hymn texts of the Veda, and dealing with questions of religious and ceremonial theory, exegesis, and so on. There are several treatises bearing this title. (See *VEDA*.)

BRAHMAPOOTRA, or **Burrampooter** ("offspring of *Brahma*"), one of the largest rivers of India, rises in Thibet at the E. extremity of the Himalaya mountains, between lat. 28° and 29° N., and lon. 97° and 98° E. Here the Taluka and Taluding unite and form the Lohit, which, after emerging from the mountain pass in a S. W. direction, assumes the name of *Brahmapootra*. Near Suddya, in about lat. 27° 50' N. and lon. 95° 30' E., it is joined by the Dihong and Dibong. The former has been traced through the Himalaya chain to lat. 28° 15' N. and lon. 95° 10' E., and is thought to be a continuation of the Dzang-bo-tzin or Sanpo, a large river which rises in Thibet N. of that range. After receiving these tributaries, the river flows 75 m. S. W. through Assam, and then diverges into the Boree Lohit and the Dihing. Uniting again after a divided course of 65 m., it flows W. through the district of Goalpara, winds around the W. extremity of the Garrow hills, separates Goalpara and Mymensing from Rungpoor, and, after sending off a branch called the Konaie, which joins it again further down, runs S. E. for 180 m. It then changes its name for that of Megna, re-

ceives part of the waters of the Ganges through the Kirtynassa, and after various windings enters the bay of Bengal by three channels: the Ganges on the W., the Shabazpoor in the centre, and the Hattia on the E. Its total length, from its source to the bay, is about 900 m.; but including the Dzang-bo-tzin, it is about 1,600 m. It is navigable from its mouth to the Dihong by the ordinary vessels of the country, and for some distance further by canoes. Through the last 60 m. of its course, it is from 4 to 5 m. wide, and studded with islands. Its waters are muddy; its banks are mostly covered with marshes and jungles, and are subject to annual inundations. During the season of the overflow, from the middle of June to the middle of September, the level districts of Assam are almost wholly submerged, so that travel is impossible, except on causeways 8 or 10 ft. high. The volume of water discharged by the river at such times is immense. Even in the dry season it is equal to 146,188 cubic feet a second, while under the same circumstances the Ganges discharges only about 80,000.

BRAHMS, Johannes, a German pianist and composer, born in Hamburg, March 7, 1833, where his father was a player on the double bass. He was placed at the age of 12 under the instruction of Edward Marxsen, and when 14 played at concerts the most difficult modern compositions as well as classical works of the older masters. He was first brought prominently into public notice by Robert Schumann, who in 1853, in his *Neue Zeitschrift für Musik*, predicted for Brahms a great career, speaking of the young composer as "one destined to give expression in an ideal manner to the deepest feelings of the age—one who will present us with the qualities of a master." Brahms has hardly filled the place that Schumann marked out for him, though his influence upon the musical art, so far as it has extended, has been exerted worthily. He has resided generally in Vienna. His works consist of sonatas, songs, trios, and other compositions for stringed instruments, choruses, and orchestral works.

BRAIDWOOD, Thomas, one of the earliest teachers of the deaf and dumb in Great Britain, died in 1806. He commenced a school for deaf mutes at Edinburgh in 1760, following the system of Heinicke and others, giving great prominence to articulation and "reading from the lip." His processes were kept a close secret in his own family for many years. He taught with considerable success at Edinburgh till 1788, when he removed to Hackney, near London, continuing his school till his death, after which it was carried on by his widow and her grandchildren. The Braidwood family long had a monopoly in instructing the deaf and dumb in England. A pamphlet, entitled *Vox Oculis Subiecta*, published in 1783 by an American whose son had been educated there, gives an account of the school at Edinburgh.

BRAILA, Ibraila, or **Brahilov** (Turkish, *Ibrail*), a town of Roumania, in Wallachia, on the

left bank of the Danube, 103 m. N. E. of Bucharest; pop. about 16,000. It is the chief port of Wallachia. The trade consists in the produce of the country, such as barley, wheat, maize, linseed, hides, tallow, timber, and tobacco. It is chiefly conducted by Greeks; but many English and other merchants are engaged in it. Braila suffered much by the Turkish wars in the 18th century, and was burned by the Russians in 1770. Afterward it was restored to the Turks, but surrendered to Russia in 1828. Since the subsequent treaty of peace of Adrianople, it has continued to form part of Wallachia.

BRAILLE, Louis, the inventor of a method of writing with points for the blind, born at Lagny, a suburb of Paris, in 1809, died in 1852. He lost his sight at the age of six years by an accident, and in 1819 was admitted to the institute for the blind at Paris. He devoted himself to the study of the piano, violoncello, and organ, and became one of the most distinguished organists of Paris. In 1827 he was appointed a professor in the royal institute, and soon after modified M. Charles Barbier's system of writing with points so as to render it practicable and convenient. This system was introduced into most of the continental schools for the blind. Braille also applied his system to musical notation.

BRAIN, a collective term, denoting those parts of the nervous system (excluding the nerves) which are contained in the cranial cavity, viz.: the brain, in its popular signification, or the cerebral hemispheres; the *cerebellum*, or little brain; and the *medulla oblongata*, or the upper part of the spinal cord. Each of these has its special part to play in the animal organism. The brain alone, of the animal tissues, is directly influenced by the mental acts of living beings, and through it are effected the mutual reactions of mind and body; the phenomena of sensation and volition, and the mysterious agency of intellect and instinct, are all manifested through the channels of the nervous centres, the most important of which is the brain. The peculiar substance through which all these actions take place exists in two forms, the vesicular and the fibrous. The vesicular nervous matter is gray or ash-colored, granular in texture, containing nucleated nerve vesicles, largely supplied with blood, and is the originator of nervous power; it is sometimes called the "cortical substance," from its forming a thin layer over the exterior of the brain; it is also found in the centre of the spinal cord. The fibrous nervous matter is generally white, firm, and inelastic, composed of tubular fibres; it is less vascular than the other, and constitutes nearly the whole of the nerves and the greater part of the spinal cord; it simply propagates the impressions sent to or from the vesicular matter. The two kinds do not occur together except in the nervous centres. In the vertebrated animals, nervous matter is a soft and delicate substance, owing the greater part of its tenacity to the

vascular and fibrous tissues connected with it. The chemical composition of nervous matter has been well ascertained by Fourcroy, Vauquelin, and Frémy; but the distinguishing characters of the gray and white substance are as yet imperfectly known. Fourcroy notices the great amount of water in the cerebral matter, from six eighths to seven eighths of its weight, upon which its softness is in great part dependent. According to Vauquelin's analysis in 1812, the brain is an emulsive mixture of albumen, fatty matter, and water holding in solution saline and other matter common to it with other tissues. The following table gives the result of his analysis:

Albumen	7-00
Cerebral fat { stearine, 4-63 }	5-23
{ elaine, 0-70 }	
Phosphorus	1-50
Osmazome	1-12
Acids, salts, sulphur	5-15
Water	80-00
	<hr/> 100-00

The medulla oblongata contains more cerebral fat, but less albumen, osmazome, and water. Frémy's analysis, published in the *Annales de Chimie*, 1841, confirmed that of Vauquelin, and showed the following proportions: 7 parts of albumen, 5 of fatty matter, and 80 of water. He extracted from the fatty matter the following secondary principles: 1, cerebrie acid, a white granular, crystalline substance, containing no sulphur, a little phosphorus, and 66 per cent. of carbon; 2, oleophosphoric acid, separated from the cerebrie by its solubility in ether, containing about 2 per cent. of phosphorus in the condition of phosphoric acid, and combined with elaine; 3, cholesterine, the same as that obtained from bile (brains preserved in alcohol are apt to be surrounded by a crystalline substance resembling cholesterine); 4, traces of elaine, margarine, and fatty acids. The brain is remarkable for containing phosphorus, which varies in quantity at different periods of life, being the least in infancy and old age; the maximum of water is found in infancy, an interesting fact in connection with the serous effusions so prevalent at this period of life; it has been ascertained that the idiot brain contains less phosphorus than the normal organ, this being diminished from nearly 2 to less than 1 per cent., indicating possibly an important hint for the treatment of diseases accompanied by deterioration of the mental powers. The microscopic elements of nervous tissue are fibres and cells. The fibrous nervous matter, or white central substance, contains tubular fibres or nerve tubes, and the gelatinous fibres found chiefly in the sympathetic system. The white fibres are membranous cylinders, of a pearly lustre, consisting of an external delicate, transparent sheath, within which is a layer of thick, fluid, highly refractive matter, called the "medullary layer;" while the central portion is occupied by a finely granular mass, termed the "axis cylinder." The medullary layer, how-

ever, is less distinct in the fibres of the brain than in those of the nervous trunks, and in some instances appears to be altogether wanting. The fibres of the brain average $\frac{1}{10000}$ of an

FIG. 1.—Nerve Fibres of the Brain.

inch in diameter, presenting at some points a swollen appearance; they do not communicate with each other like the vessels, nor divide into smaller fibres, but continue unbroken from their origin to their final distribution, inosculating only at their terminal loops. The gelatinous or gray fibres seem to be solid, flattened, transparent filaments, varying in diameter from $\frac{1}{10000}$ to $\frac{1}{40000}$ of an inch; the mode of their connection with the elements of the nervous centres is unknown. The essential elements of the vesicular or gray nervous matter are cells, or vesicles, containing nuclei and nucleoli; they are dark, generally globular, but at times very irregular and variously elongated, enclosing a grayish granular substance, and sometimes pigment granules; they vary in size from $\frac{1}{10000}$ to $\frac{1}{30000}$ of an inch in diameter; among the largest of these are the caudate, so called from the irregular tail-like process extending from them.

FIG. 2.—Nerve Cells of the Brain.

The nerve vesicles are imbedded in a soft granular matrix in the brain. The nervous centres exhibit the union of these two forms of matter, more widely separated in the brain than in the

smaller ganglia; indeed, the cerebral hemispheres are composed internally of fibrous matter exclusively, surrounded by a layer of the gray vesicular substance, into which the fibres are also prolonged. The tubular fibres seem to be capable of regeneration to a certain extent; if the nerve be divided, but the ends not separated, union may take place, and the nerve resume its office; even when a portion is excised, it appears that true nerve fibres, in smaller number than in the nerve itself, may be developed in the uniting substance, as shown by partial restoration of function and microscopic examination. When a portion of the brain is removed by accident or design, its place is supplied by new substance; but whether this be true cerebral substance or not has not been satisfactorily determined. The white fibres may be distinguished, according to their physiological office, into three kinds—efferent or motor, afferent or sensitive, and commissural or connecting. Henle suggests that there may be a fourth series, associated with the operations of thought. Of the mode in which the afferent nerves terminate, and the motor nerves commence in the central organs, it may be said that three principal modes have been ascertained, in which there is an actual continuity from one form of nerve tissue to the other: a globular unipolar cell may give out a single prolongation, which becomes a fibre; or a nerve cell may be found in the course of a tube, with each extremity prolonged into a fibre; or some of the radiating prolongations of the caudate cells may become continuous with the axis cylinders of nerve tubes, or inosculate with those of other caudate cells. A curious circumstance in connection with the gray matter is the large quantity of pigment or coloring substance in it, apparently forming one of its essential constituents, as it is everywhere present, though in some situations more abundantly than in others; it has been asserted that this bears a close resemblance to the coloring matter of the blood, and if so, it is a fact of great interest to physicians, who can avail themselves of the restorative properties of iron in cerebral diseases, improving the quality of the nutrient blood by increasing the quantity of the red globules.—The central column or spine of the vertebrate skeleton encloses in its canal the spinal cord; and the cranium, which is a series of modified and expanded vertebrae, protects the continuation of the cord and its expansion into an aggregate of gangliform swellings, the brain or encephalon. The brain is enclosed in three membranes, or *meninges*, continuous with those of the spinal cord, which will be described under that head. From without inward, these membranes are the *dura mater*, *arachnoid*, and *pia mater*. The term *mater* (μήτηρ, mother) originated with the Arabians, who considered these membranes as the parents of all others in the body. The *dura mater* is a membrane of white fibrous tissue, strong, flexible, but not elastic; its fibres are arranged on different

planes; it is freely supplied with blood vessels, and is perforated for the passage of nerves, and, according to Arnold and Pappenheim, has some branches between its own laminae. It forms the internal periosteum of the skull, and is closely applied to the cranial bones, and in some places firmly adherent, especially in youth and old age. From it processes are

FIG. 3.—The Brain enclosed in the Dura Mater.

given off, which serve as partitions between the cerebrum and cerebellum behind, and between the cerebral and cerebellar hemispheres; these processes are the *falx cerebri*, which separates the great hemispheres, extending on the median line from the forehead to the occiput, along the sagittal suture; it is falciform in shape, its lower border concave and corresponding to the convexity of the *corpus callosum*, and its upper border enclosing the great longitudinal sinus; narrow in front, and deep behind, having the inferior longitudinal sinus along its posterior border. The *tentorium cerebelli* extends horizontally between the posterior cerebral lobes and the cerebellum; it is attached to the *falx cerebri*, and to the occipital and petrous portion of the temporal bones along the groove for the lateral sinus; in the cats and some other leaping animals, this membrane is partially replaced by bone, doubtless to prevent injury from sudden shocks. Between the lobes of the cerebellum descends vertically from the tentorium the *falx cerebelli*, containing the occipital sinuses. Next to the dura mater, which also furnishes sheaths for the nerves and vessels at their origins, lies the *arachnoid*, the serous membrane of the cerebro-spinal cavity; it consists of two layers, the outer one closely adherent to the dura mater, and the inner one loosely to the pia mater; the space between the two layers is the arachnoid cavity, and that between it and the pia mater, the sub-arachnoid cavity; resembling other serous membranes, the arachnoid is liable to become inflamed, with the effusion of fluid into one or both of the above cavities, especially toward the base of the brain. The sub-arachnoid space is filled with what is called the "cerebro-spinal fluid," varying in quantity from two or three ounces in the healthy adult condition to ten or twelve ounces in old age. It keeps during life the opposed arachnoid surfaces in contact;

it is most abundant where the brain has shrunk either from disease or advanced age. From the experiments of Magendie it appears that its presence is necessary for the healthy action of the nervous centres; when removed, it is quickly formed again; it is a limpid, alkaline fluid, doubtless secreted by the pia mater, and affords mechanical protection to the brain and spinal cord by the interposition of its yielding medium between them and the bony parietes which surround them; its accumulation at the base of the brain is highly favorable for the protection of the large nerves and vessels there situated. This fluid exists in an increased quantity in the brains of idiots; and whenever the cranial or spinal walls are deficient, as for instance in *spina bifida*, an accumulation of the fluid becomes prominent at the part, thereby protecting the nervous substance. The third membrane immediately investing the brain is the *pia mater*, composed of white fibrous tissue and blood vessels; in the skull it is very delicate and very vascular; it adheres to the surface of the cerebral and cerebellar hemispheres, and sends innumerable minute vessels to their substance; it sinks into the fissures and sulci, and penetrates into the ventricles, forming the *choroid plexuses* and the *velum interpositum*; its minute ramifications are sometimes incrustated with sandy particles, consisting principally of phosphate of lime. The pia mater is the medium of nutrition to the nervous substance and to the arachnoid; and hence any inflammation of these membranes would be communicated to the superficial gray matter of the brain, the seat of its physiological activity. Along each side of the longitudinal sinus it is common to find a series of depressions in the dura mater; these are due to the presence of whitish granules, called Pacchionian glands, from their first describer, of an albuminous material, arising probably from a deposit of granular lymph among the vessels of the pia mater; they are found principally along the edge of the great longitudinal fissure of the hemispheres, pushing the arachnoid before them, and even projecting into the sinus. They are generally considered morbid structures, and the result of local irritation of a chronic character; if the products of disease, they do not seem to interfere in the least with the functions of the brain.—The brain of the adult human male, comprising the whole contents of the cranium as far as the occipital foramen, will average in weight about 50 oz.; that of the adult female, about 45 oz.; the maximum weight of the healthy organ is about 64 oz., and the minimum about 31 oz.; in cases of idiocy it has been found weighing only 20 oz. According to Bourguery, if the brain be divided into 204 parts, the cerebral hemispheres would weigh 170, the cerebellum 21, and the medulla and sensory ganglia 13; on the same scale, the spinal cord would weigh 7. In proportion to the body's weight, the brain of man would weigh $\frac{3}{16}$ part; in the average of mammalia this proportion would be $\frac{1}{16}$; in

birds, $\frac{1}{12}$; in reptiles, $\frac{1}{18}$; and in fishes, $\frac{1}{88}$. In some apes, rodents, and singing birds the weight of the brain bears a higher proportion to that of the body than it does in man, even as high as $\frac{1}{12}$ in the blue-headed titmouse; the increase, however, is not in the cerebrum, the seat of intellect, but in the sensory ganglia, the seat of the instinctive actions. The size of the brain is not in proportion to the physical development of the body, either in animals or man; the horse has a brain inferior in weight to the smallest adult human brain; that of a whale 75 feet long was found to weigh not quite twice as much as that of a man. Even in men there is no fixed relation between the size of the body and of the brain; a small man may have a large brain, and *vice versa*. Men of great intellectual power have generally, if not always, possessed large brains; the brain of Cuvier, the great French naturalist, weighed between 59 and 60 oz.; that of the French surgeon Dupuytren, 58 oz.; those of Napoleon and Daniel Webster, an ounce or two less. The quality of the brain, however, is quite as important as the quantity, so that a large brain does not of necessity constitute a great man. According to Tiedemann, the female brain, though absolutely smaller than that of the male, is larger when compared with the size of the body. The brain reaches its highest development anatomically at the age of 20 years, which it maintains until 60, after which, in most persons, it begins to decrease in size, with a corresponding decline in the mental powers. There do not appear to be any striking differences between the brains of the various races of man.—For the topographical and pathological anatomy of the brain, an examination from the hemispheres downward is the most practicable method; but for physiological anatomy, it is more advantageous to make the examination from below upward, by which method the student proceeds from the simple to the more complex, following the direction of the fibres of the medulla oblongata to their ultimate distribution in other parts of the brain. The medulla oblongata is the upper enlarged portion and direct continuation of the spinal cord, extending from the plane of the occipital foramen about an inch upward to the *tuber annulare*; through this the brain is brought into communication with the other vital organs, and it is therefore the *nœud vital*, “the link which binds us to life.” As its size is proportionate to that of the nerves which proceed from it, it is much larger in some lower animals than in man. Like the spinal cord, it consists essentially of anterior and posterior columns; it may be anatomically distinguished from the cord by the decussation or crossing of some of the anterior fibres. In front are the “anterior pyramids,” separated by a median fissure; external to these are the oval protuberances, the “olivary bodies;” more external, and forming the lateral and great part of the posterior portions, are the “restiform bodies,” separated from each other in the mid-

dle by two slender columns, the “posterior pyramids.” The anterior pyramids or fibres extend from the antero-lateral columns of the cord to the cerebral hemispheres, passing through the *tuber annulare*, the *corpora striata*, and the *optic thalami*, contributing to form the lower portion of the *crus cerebri*; in the tuber annulare these fibres are crossed at right angles by others belonging to it, and are interlaced with them; on tracing them downward, the greater part connect themselves with the middle or lateral columns of the opposite side, while a few are continued down on the same side into the anterior columns of the cord, and others, the “arciform fibres,” curve round the olivary bodies and ascend to the cerebellum, not passing to the cord; the anterior pyramids are entirely of a fibrous structure. The arrangement of these fibres is highly interesting in explaining the phenomena of disease of the brain; since, owing to the decussation of the fibres in the medulla oblongata, an injury of the right side of the brain will produce paralysis on the left side of the body, and *vice versa*; while a lesion of one lateral half of the spinal cord, below the point of decussation, causes paralysis of the same side of the body. The restiform bodies consist of fibrous strands enclosing a gray nucleus, and pass upward into the *crura cerebelli*; below they are chiefly continuous with the posterior spinal columns, and partly with the posterior part of the middle columns; as the fibres ascend they diverge, leaving between them the fourth ventricle, and pass into the corresponding hemisphere of the cerebellum, connecting this latter with the spinal cord; the cerebellar columns also communicate by a band of arciform fibres, according to Solly, with the anterior spinal columns; the gray nucleus, or “restiform ganglion,” seems to be the ganglionic centre of the pneumogastric and a part of the glossopharyngeal nerves. The posterior pyramids can hardly be distinguished from the restiform bodies externally; but their columns, bounded by the median fissure and by a very slight groove, establish a connection between the sensory tract of the *crura cerebri* and the posterior columns of the cord; their gray nuclei are the ganglionic centres of the auditory nerves. The olivary bodies, continuous inferiorly with the anterior or motor columns of the cord, and affording attachments to the motor fibres of the first and second cervical nerves, enclose a gray nucleus, and send their fibres forward to the motor tract of the *crus cerebri*, and backward to the quadrigeminal bodies; the nucleus, or *corpus dentatum*, seems to be connected with the hypoglossal or motor nerve of the tongue, and also with the glossopharyngeal, one of the sensory nerves of this organ. The medulla is not only a transmitter of fibres from the spinal cord, but is a nervous centre itself; with it are connected the nerves of respiration and deglutition, which are quite independent of the cerebral hemispheres, and beyond the control

of the will.—The cerebellum, one eighth of the size of the cerebrum, is placed under the posterior part of the latter, from which it is separated by the *tentorium*; it is composed of white and gray matter, the former occupying the interior; its convolutions have the form of parallel layers. Its central part or lobe is the only one found in fishes and reptiles; its lateral lobes, found only in the higher animals and in man, indicate an advance in development. On a vertical section we find the white substance resembling the trunk of a tree from which branches are given off, hence called *arbor vite*, or tree of life. This organ is connected with the rest of the brain by three sets of fibres, the superior extending to the *tubercula quadrigemina*, the middle or the restiform fibres passing downward to the medulla, and the inferior or transverse (*pons Varolii*) passing to the opposite side and forming a considerable part of the tuber annulare; the central lobe has aggregates of lobules on its superior surface,

FIG. 4.—Profile view of Human Brain, in vertical section, showing the medulla oblongata, the tuber annulare, the middle portion of the cerebellum with the *arbor vite*, the central parts of the cerebrum, and the convolutions on the inner surface of the hemispheres.

containing both white and gray matter, the "superior vermiform processes," and on the lower surface the "inferior vermiform processes." The transverse diameter of the cerebellum is $3\frac{1}{2}$ to 4 inches, the length 2 to $2\frac{1}{2}$ inches, and its thickness varying from 2 inches in front to less than $\frac{1}{2}$ inch behind. For details on the structure and on the intricate divisions of the cerebellum, the reader is referred to special works mentioned at the end of this article. Disease of the cerebellum, when deep-seated, is generally manifested on the opposite side of the body; this organ presides principally over the regulation of the voluntary movements. The restiform bodies of the medulla in their ascent to the hemispheres of the cerebellum diverge, leaving a lozenge-shaped cavity, the fourth ventricle, bounded above by the median cerebellar lobe, below by the olivary columns, behind by the nodule of the inferior vermiform process, in front by a portion of the superior vermiform process, called the "valve of Vieussens;" on

the floor are the white barb-like fibres of the seventh pair of nerves, passing at right angles, and called the *calamus scriptorius*; it is improperly called the ventricle of the cerebellum, as it belongs to the medulla and is proportionate to it in size. The *mesocephalon*, or *tuber annulare*, embraces those portions of the brain which unite the cerebrum above, the cerebellum behind, and the medulla below; the lower surface, or the pons Varolii, consists of curved transverse fibres, passing from one crus cerebelli to the other, crossing apparently over the anterior pyramids like a bridge; they are always developed in proportion to the cerebellar hemispheres, and are absent in animals having only the median lobe; they constitute the great transverse commissure of the cerebellum, as the *corpus callosum* (mentioned hereafter) constitutes the great transverse commissure of the cerebrum; these fibres extend more than one half of the depth of the tuber annulare. The tuber annulare, which exists in animals whose cerebellum has no hemispheres, projects from the medulla proper, and contains a nucleus of gray matter; Longet is of opinion that this ganglion is an independent centre of sensation and motor power, and Dr. Todd states that the convulsions excited by a current of electro-magnetism through it are not tetanic, but epileptic, or alternating with relaxations of the muscles. Situated above the tuber annulare are the quadrigeminal bodies, the two anterior being called *nates*, and the two posterior *testes*; they are gangliform bodies, containing gray and white matter, the anterior being the larger; these are the analogues of the optic lobes of birds, reptiles, and fishes, in which classes there is only a single pair, but of much larger size. The crura cerebelli, which apparently emerge from the posterior angles of the tuber annulare, derive their fibres from strands going to the testes, from those of the restiform body, and from those of the pons Varolii; from the anterior angles of the tuber annulare diverge two similar processes of considerable thickness, the crura cerebri, which enter the cerebral hemispheres, and upon which each of these masses has been said by Dr. Todd to rest as a "mushroom upon its stalk." The fourth and fifth pairs of nerves are intimately connected with the tuber annulare. On making a section of the crura cerebri, three planes of nervous matter may be seen: the lower one, of fibrous matter, continuous with the tuber annulare and the anterior pyramids, passes up into the *corpora striata*, or striated bodies; above this is a dark mass, the *locus niger*, containing large caudate vesicles abounding in pigment, with nerve fibres among them; the upper layer, of grayish matter, continuous with the central part of the medulla oblongata, or olivary columns, passes up into the optic thalami. The striated bodies and optic thalami are best seen by laying open the lateral ventricles, in which they are placed, closely united to each other, the former being a little in front and outside of the latter. The striated bodies are

pear-shaped, tapering gradually backward in a long process which winds down into the anterior extremity of the descending horn of the ventricle, and striated when cut in an oblique

FIG. 5.—Human Brain cut open horizontally, to show its internal parts. *a*. Corpus striatum of the right side. *b*. Optic thalamus of the right side. Both these bodies are seen on the floor of the lateral ventricle, which is represented as cut open. *c*. Anterior pillars of the fornix, cut off at the level of the corpus striatum. *d*. The middle transverse commissure, passing across from side to side, between the two optic thalami. *e*. The pineal body. *f, f*. The tubercula quadrigemina. *g*. direction upward and outward, on account of the passage of the fibres of the crura cerebri into the vesicular matter; through these bodies, by three sets of fibres, communications are established between the tuber annulare, medulla oblongata, and cerebral convolutions; they are generally considered the more essential part of the nervous system which controls voluntary movements. The optic thalami are of a lighter color, of the same texture and appearance as the olivary columns, of which they are the continuations; a portion projects into the ventricles, and the rest adheres to the striated bodies, the hemispheres, olivary columns, and quadrigeminal tubercles; the fibres no doubt are continuous with those of the white substance of the hemispheres, and with those of the striated bodies; between them is the third ventricle, the roof of which is formed by the *velum interpositum*, a process of the pia mater. The *corpora geniculata, externum and internum*, are small gangliform masses, projecting from the posterior part of the optic thalami. Behind the third ventricle is a conical, dark gray body, enclosed by a process of the pia mater, the "pineal body;" it rests in a groove between the nates, and is connected with the thalami by fibres, called peduncles; it consists chiefly of large nucleated vesicles, with a few fibres, and in a cavity near the base contains a sandy substance composed of phosphate and carbonate of lime; its use in the economy is unknown. The optic thalami

have been considered but the principal sensitive centres, without which the sensorium could not perceive the physical change resulting from a sensitive impression; but this is by no means certain.—The cerebral hemispheres constitute the great mass of the brain, and their horizontal section presents an oval, of which the smaller extremity is directly forward; the external surface is smooth, being covered by the arachnoid membrane; they are divided longitudinally along the middle line by the deep fissure which receives the falx cerebri, and at the bottom of which in the middle portion is the great commissure, the *corpus callosum*; the inferior surface, or base of the brain, is divided into anterior, middle, and posterior lobes, corresponding with the *fossae* in the cranial bones; the anterior lobe rests chiefly on the roof of the orbits, and on its inferior surface presents the nerve of smell; between it and the middle lobe is the "fissure of Sylvius," through which runs the middle artery of the brain; the middle lobes are gradually lost in the posterior, which are separated from the cerebellum by the tentorium. The space between the middle lobes in the centre is occupied by the pituitary body, crossing of the optic nerves, and the mammillary bodies. The pituitary body is lodged in the *sella turcica* of the sphenoid bone, and is a glandiform mass, surrounded by the coronary sinus, and connected with the brain by the infundibular process; it has two lobes, and somewhat resembles the vesicular substance of the brain; its use is unknown. Between the crura of the cerebrum the third pair of nerves emerge. The usual way of examining the hemispheres is to make a horizontal section at about one third from the summit; this section, denominated the *centrum ovale majus*, presents a centre of white substance, surrounded by a narrow border of gray, showing the zigzag outlines of the convolu-

FIG. 6.—Cerebral Hemispheres, viewed from above.

tions, and spotted by numerous small red points caused by the escape of blood from the cut ends of minute vessels. In the central line is a broad band of white substance, uniting the hemi-

spheres together as their great commissure, and securing their connected action, the fibres passing from one to the other like a bridge; at its anterior and posterior extremity it is folded downward toward the base of the brain. On cutting a little deeper, an irregular cavity is opened on each side, the lateral ventricle, containing the striated and optic bodies; these cavities are lined by a serous membrane, secreting a fluid, the undue accumulation of which constitutes *hydrocephalus internus*, or water on the brain, a fatal disease of children, in which the substance of the brain may become almost obliterated, and the bones of the yet ununited skull distended almost to the size of an adult head. The fifth ventricle is the space between the layers of the *septum lucidum*, an extension of fibrous matter connecting the anterior reflection of the corpus callosum with the horizontal fibrous stratum called the *fornix*, and separating the anterior horns of the lateral ventricles. Between the optic thalami and striated bodies in the ventricles, in a superficial groove, is the *tenia semicircularis*, a delicate band of fibrous matter, commissural in its character. The posterior horn of the lateral ventricle, according to Owen, is peculiar to man, as also is the *hippocampus minor*, a projection of one of the convolutions into it; in its inferior horn is the *hippocampus major*, and a considerable portion of the vascular choroid plexus. The cerebral hemispheres, after the membranes have been removed, present a peculiar folded arrangement of their surface, the

FIG. 7.—Portion of Right Hemisphere of the Human Brain, divided horizontally, showing the convolutions, and arrangement of white and gray matter.

“convolutions;” the folds consist of a layer of gray matter, varying from one eighth to one quarter of an inch in thickness. Physiology has shown that the gray matter of the

nervous centres is the originator of nervous force, while the white matter serves only to convey impressions to or from the different parts of the body; hence the greater number of these convolutions, or, in other words, the greater the amount of the gray substance, the greater will be the physiological power of the brain. In the rat and the mole the surface of the brain is quite smooth; from these the convolutions increase in number up to man. Their arrangement, though never the same in two brains, nor on opposite sides of the same brain, cannot be supposed to be purely accidental; there are certain ones always present (when any exist), whose situation and size influence the disposition of the others; in man the variable and additional convolutions are chiefly on the top and front of the hemispheres. The lower the position of an animal in the scale, and the less developed the organ as we approach infancy, the greater is the symmetry of the two sides. It is said that the convolutions in the inferior races of man (Todd and Bowman) present a more symmetrical arrangement than is usually found in the more cultivated races. If the gray matter of the cerebral convolutions and the cerebellar layers were spread out, it would occupy about 670 square inches, which by this admirable arrangement are packed into the small extent of the brain. Each convolution consists of a fold of gray matter enclosing a process of the white; the gray matter forms a continuous unbroken sheet over the cerebral surface; the greater part of the white fibres emerge from the gray matter, and thence converge to the central parts of the brain. The fibres which unite different portions of the same or of opposite hemispheres are called “commissures;” the transverse are the corpus callosum, the anterior, posterior, and soft commissures; the longitudinal are the fornix and the superior longitudinal commissure. The corpus callosum connects the great bulk of the hemispheres, especially at the lower part; it is wanting in fishes, reptiles, birds, and the lower mammals. The anterior commissure particularly unites the striated bodies, many of its fibres passing through them and radiating to the middle cerebral lobes; it is very large in the marsupials, which have no corpus callosum. The posterior commissure connects the optic thalami, and is connected with the pineal body. The soft commissure also passes from one optic thalamus to the other, dividing the third ventricle into an upper and lower portion; unlike the other commissures, it contains gray matter. The superior longitudinal commissure is enclosed in the convolution overhanging the corpus callosum, and connects the anterior and middle lobes with the posterior. The *fornix* or vault is the most remarkable, extensive, and complicated of all the commissures; it is situated immediately under the corpus callosum, with which it is closely connected posteriorly; it may be divided along the median line into two

portions, one belonging to each hemisphere. Of this complicated structure it can only be said here that it begins at the optic thalamus, proceeding anteriorly to the base of the brain, where it turns suddenly upward and forward, thus forming the *corpora albicantia* or *mammillaria*, and, ascending toward the corpus callosum, passes along its lower surface, spreading laterally into what is called its "body;" it again descends at the back part of the brain, some of its fibres going to the posterior lobes, and others crossing the hippocampi to be connected with the middle lobes; it thus connects those parts of the convolutions of one side beneath the corpus callosum. Other probably commissural structures are the *pons Turini*, in the angle formed by the divergence of the crura cerebri, and probably connecting their fibres; the innermost fibres of the optic tracts are evidently commissural, connecting the quadrigeminal and geniculate bodies of opposite sides; the *tuber cinereum* is a layer of gray matter, containing many nerve tubes, extending from the mammillary bodies to the posterior curves of the corpus callosum, and forming intimate connections with the fornix, optic tracts and thalami, and the pituitary body. The fibres connecting the cerebrum with the cerebellum are very few; the principal, if not the only ones, are those going to the testes from the cerebellum.—An organ of such importance as the brain must require a large supply of blood; this is afforded by the great carotid arteries, coming directly from the aorta, and the vertebral branches of the subclavians, which meet at the base of the organ, freely communicating with each other. These arteries, coming so directly from the aortic arch, are prevented from injuring the delicate brain: 1, by the blood ascending against gravity; 2, by the curving of the vessels like the letter S before they enter the cranium, thus scattering the force of the stream in different directions; 3, by the minute subdivision of the vessels before they enter the cerebral substance. The impure blood returns through the jugular veins; hence any compression of these vessels by a tight neck stock, or the like, impedes the whole cerebral circulation, causing, it may be, dangerous congestions. If the blood could be shut off completely from the brain, death would instantly ensue; and to prevent the possibility of this accident, the vertebral arteries are protected by the bony canals of the cervical transverse vertebral processes from all danger of compression or ordinary injuries. The brains of persons who have died by hanging always exhibit great venous congestion. The veins of the dura mater are quite remarkable by pouring their contents into the large canals enclosed between its layers, the sinuses; these, unlike ordinary veins, cannot be distended beyond a certain point, and, as they all empty their blood into the internal jugular vein, any obstruction in this or in the superior vena cava very speedily produces an uncomfortable dis-

tention in the head. These sinuses are the superior longitudinal, corresponding to the superior margin of the falx cerebri, commencing near the root of the nose (*crista galli*) and terminating in the cavity called *torcular Herophili*, near the internal occipital protuberance; the inferior longitudinal sinus runs along the lower border of the falx, and ends in the straight sinus, which runs in the median line at the meeting of the falx and the tentorium, and opens into the torcular; the lateral sinuses extend from the torcular downward and forward to the jugular veins. This is the largest sinus, and its canal is deeply hollowed out of the occipital and temporal bones; that of the right side is generally the larger. The sinuses are sometimes the seat of dangerous inflammation. Between the layers of the falx cerebelli are the occipital sinuses, opening into the torcular; the petrosal sinuses, running along the petrous portion of the temporal bone, open into the lateral sinuses; the cavernous sinuses are on each side of the sella turcica, communicating with the petrosal by the transverse sinus, and with each other by the circular sinus. From this arrangement of the sinuses, communicating freely with the external vessels, may be understood the signal advantages of local depletion in relieving vascular fulness within the head, and also the utility of cold applications for similar purposes.—There are 12 pairs of nerves belonging strictly to the brain, which differ from spinal nerves only in their distribution and in coming through openings in the skull instead of between the vertebrae; all, except the first, proceed from the spinal cord itself, or from its prolongation in the brain (the medulla oblongata). These nerves are: 1, the olfactory, or nerve of smell; 2, the optic, or nerve of vision; 3, *motores oculorum*, the motor nerves of all the muscles of the orbit, except the superior oblique and the external rectus; 4, the *pathetici*; 5, the trifacial or *trigemini*, the general sensory nerve of the head and face; 6, the *abducentes oculorum*; 7, the facial, the motor nerve of the face; 8, the auditory, or nerve of hearing; 9, the glossopharyngeal, supplying part of the sensory fibres of the tongue, and presiding over the movements of swallowing; 10, the pneumogastric, or *par vagum*; 11, the spinal accessory (the last two combined presiding over the functions of respiration and phonation); and 12, the hypoglossal, the motor nerve of the tongue. Philosophical anatomists have combined these nerves in various ways, separating the three nerves of special sense, and classifying the others in groups resembling spinal nerves, with their anterior motor, and their posterior sensitive roots. As the skull may be considered as composed of three cranial vertebrae, we have the olfactory, optic, and auditory special nerves, making their way out through the three vertebrae which may be called by the same name, corresponding to the three primary vesicles which are developed into the brain. Of the intervertebral, analogous to spinal nerves, the

first group is composed of the fifth pair for its sensory portion, and of the third, fourth, and sixth for its motor portion; secondly, we have the facial and glossopharyngeal nerves com-

FIG. 8.—Human Brain, viewed from below. *a.* Anterior lobe of cerebrum. *b.* Middle lobe of cerebrum. *c.* Posterior lobe of cerebrum. *d.* Cerebellum. *e.* Medulla oblongata. *f.* Tuber annulare. 1. Hypoglossal.

bined; and lastly, the par vagum and spinal accessory form the third group; the hypoglossal may be considered as the first of the true spinal nerves. For further details on this subject the reader is referred to the works of Oarns, Oken, Owen, and other writers on philosophical anatomy. The nature of the nervous force, the functions of the nerves, and the general physiology and pathology of the subject, will be treated under NERVOUS SYSTEM; only a brief summary can be given here.

Without question the various operations of the mind are associated with the cerebral convolutions; perception, memory, the power of abstraction, imagination, &c., possess, as instruments of action, the folds of gray matter; as Cuvier says, these parts are the sole receptacles in which the various sensations may be as it were consummated, and become perceptible to the animal. Mechanical injury to the convolutions and the central white substance occasions no pain nor disturbance of the motive powers; in many diseases of the brain and its membranes convulsions accompanied by pain occur, but this depends on a change produced in the striated and optic bodies, and through them propagated to the motor and sensitive nerves. On removing the hemispheres animals are thrown into a state of deep sleep, retaining their muscular power, yet apparently incapable of a single mental nervous action, voluntary or sensory. When the membranes are inflamed, especially the pia mater, the mental faculties are always disturbed; in the delirium of fevers, in delirium tremens, &c.,

the circulation of the convolutions seems to be disturbed. The convolutions, then, are the centre of the intellectual actions; being connected with the striated and optic bodies (which have been regarded as the centres of volition and sensation), the intellectual centre may either excite or be excited by them. When the convolutions are insufficiently supplied with blood, the deficient nutrition occasions deranged phenomena of thought and a rapid development of ideas, which, being ill or not at all regulated by the will, assume the forms of delirium and insanity, just as disease of the nerves of vision and hearing may produce unnatural sights and sounds. As in every muscular action some portion of the muscular tissue is wasted, to be supplied by the general nutrition of the body, so every thought is doubtless accompanied by some change in the nervous centre. Concussion of the brain from a fall or blow, or condensation of its substance by a clot of blood, checks the organic changes of the surface, and interrupts the joint actions necessary for consciousness. Gall, the founder of phrenology, assigned to certain convolutions certain faculties of the mind, moral feelings, and instinctive propensities. This theory has since his time been pursued with the zeal which must naturally attach itself to any science which professes to read the mental tendencies from external signs. In regard to phrenology, it can only be remarked here that, while it is undoubtedly true that the energy of a nervous centre bears a certain relation to its size, the stress laid by its followers on the temperaments shows that they consider the quality of the brain an important element in the development of nervous power.—During sleep the nervous centres obtain the rest necessary to repair the waste of daily activity; in this state the brain refuses or is slow to convey impressions from without. In deep sleep we are unconscious, and may be motionless; as the sleep becomes lighter, consciousness begins to return, and mental changes take place, constituting dreams of various kinds. Man performs many actions instinctively, without the intentional adaptation of means to ends, just as the bee makes its cell, or the bird its nest; children are born and live for some time without cerebral hemispheres, who perform the acts of sucking and swallowing perfectly well; remove the hemispheres in an animal, and it will eat if food be placed in the mouth, though it will not go to seek it; many idiots will do the same. In what part of the brain resides the power presiding over these actions? At the base of the brain, concealed by the hemispheres, is a series of ganglia, the origin of the nerves of special sense, as well as the striated and optic bodies into which all the fibres connecting the hemispheres with the medulla oblongata pass; these nerves have therefore their own nervous centres, distinct in function from other parts of the brain. In fishes these ganglia are very large, and the hemispheres comparatively small, sometimes smaller than a single pair, the

optic. In man the instinctive propensities are in a measure superseded by intelligence, but they may act independently of it. The real nervous centres for motion and sensation are those situated at the base of the brain, and not the hemispheres; as far as mere animal life and motion are concerned, the latter are not essential; a vast proportion of animated creatures (all the invertebrata) have no trace of them; they are added in man for the intellectual and moral nature. The instinctive and emotional actions are excited through the special ganglia, following directly upon sensation, without any process of thought; they are sometimes stronger than the voluntary actions; *e. g.*, we are often compelled to laugh at something ludicrous though we have the strongest motives not to do so. Long-continued habit will often make us perform actions instinctively, as it were, which at first required an effort of the will: for instance, in an old snuff-taker, who had been seized with epilepsy, irritation of the nose with a feather to restore consciousness produced a contraction of the right forefinger and thumb to take a pinch. These emotional actions may be excited by mental operations. Whenever the feelings get the better of the reason, the sensory ganglia are excited at the expense of the hemispheres, and the individual is for the time being morally insane, even though these emotions may point in the right direction; fanatics of all classes, in this way, are really insane, generally monomaniacs. These instincts may also be in opposition to the reason, and then the more a man follows them the closer does he approach the brutes. Comparative anatomy teaches that the cerebellum is largest in those animals which have the greatest variety of motions; injury or removal of this organ causes no pain nor convulsions, but destroys the power of combining properly the voluntary motions. Man, though inferior to many animals in particular kinds of movements, far surpasses them in the number and complexity of their combinations; the act of walking brings into action almost every muscle of the trunk and extremities, and is superior to all other modes of exercise. In man the cerebellum attains its highest development. Inflammation of its membranes, and even its almost complete destruction by slow disease, has little effect on the intelligence, but the motive powers are disturbed. In intoxication the energy of the cerebellum is first destroyed, and afterward the intelligence and consciousness, leaving the subject for the time little better than dead, motionless, and insensible. The distinct operation of these various centres is made obvious by many conditions of the body, in which one or more are inactive. In deep sleep, the hemispheres, the sensory ganglia, and the cerebellum are more or less completely at rest, but the medulla oblongata and the spinal cord must, as always, be wide awake; in dreaming, the hemispheres are partially active; in somnambulism, a step nearer to wakefulness, the hemispheres are awake, and

also the cerebellum, so that the movements are well adapted to the thoughts. It is well known that in this state persons have walked over dangerous places which they could never have passed in open day; there is an evident loss of control over the thoughts, which are more influenced by external impressions than in dreaming, so that the somnambulist may answer questions properly; that there is not full command over the senses, the dangerous accidents occurring in this condition fully prove; the events of this state may not be remembered in the waking hours, but may be taken up again by the memory the next night, constituting complete "double consciousness." A condition remarkably analogous to somnambulism is the mesmeric sleep or trance; a nervous habit of body predisposes to both. Overworking the brain exhausts the body; wear and tear of the brain, like wear and tear of the muscles, require periodic and long intervals of rest; from want of attention to this fact, many a bright intellect has faded into imbecility and insanity.—The primary ganglia of the vertebrate brain are three in number, and they are developed into the anterior or cerebrum, the posterior or cerebellum, and the median or quadrigeminal bodies. In fishes, the lowest vertebrates, the medulla is large, with the pyramidal and restiform bodies, but without the olivary; the brain looks like a series of ganglia developed on the superior surface of the cord, two pairs and a single one: 1, the olfactory lobes, analogous to the hemispheres in man, from which the nerves of smell arise; 2, behind these, the optic lobes, generally considered analogous to the tubercula quadrigemina, in some fishes larger than the other parts of the brain; from these arise the optic nerves, and the third, fourth, and sixth pairs; 3, behind these, the imperfectly developed cerebellum generally, but of large size in the selachians. In reptiles the brain well fills the cranial cavity, and the preponderance of the spinal cord is less; the olfactory lobes, now obviously the hemispheres, are increased in size, with an internal cavity, and a commissure; the second cerebral mass and its cavities are smaller; the cerebellum is small in the lower orders, but with lateral appendages and external striæ in the higher. In birds the brain and spinal cord are no longer on the same plane; the brain is the larger, and the ganglia are more above and less behind each other; the hemispheres are larger than the other parts, are united by commissures, and contain true lateral ventricles in which is a tubercle resembling a corpus striatum; the optic lobes are small, separated, with smaller cavities; the cerebellum is particularly large, with evident lateral lobes and external striæ. In mammals the brain is much larger than the cord; the cerebral hemispheres are of large size, with marked convolutions in the higher orders, with a corpus callosum, lateral ventricles with anterior, descending, and (in the monkey) posterior horns, optic and

striated bodies, *tænia semicircularis*, and for-nix; the optic lobes are small, divided into two pairs, solid, and are now called the *tubercula quadrigemina*; the cerebellum is highly de-veloped, the more so as the animal approaches man, presenting the *arbor vitæ* in its interior; the pons Varolii is large, and the fourth ven- tricle is completely concealed and shut in. Prof. Owen has divided the mammalia into four groups, according to the characters of the surfaces of the cerebral hemispheres; in some the hemispheres are but feebly con- nected by the fornix and anterior commis- sure, while in the great majority the corpus callosum is added; in the former case there is a peculiar mode of development of the young owing to the absence of the placenta. His groups are as follows: 1, *lyencephala*, hav- ing the hemispheres loose and disconnected, leaving exposed the olfactory ganglia, cerebel- lum, and more or less of the optic lobes, their surface smooth, or with very few anfractuosi- ties; this includes the marsupials; 2, *lissence- phala*, having a corpus callosum, with the cere- bellum and olfactory lobes exposed, the surface smooth, or with very few and simple convolu- tions; this includes the rodents, insectivora, cheiroptera, and edentata; 3, *gyrencephala*, having the cerebrum extending over more or less of the cerebellum and of the olfactory lobes, with more or less numerous convolu- tions; this includes cetacea, pachydermata, herbivora, carnivora, and quadrumana; 4, *archencephala*, embracing man only.—Those wishing to pursue the study of the brain are referred to the works of Solly, Longet, Leuret, Todd and Bowman, Carpenter, Owen, Tiede- mann, Müller, and to the researches of J. Lock- hart Clarke on the "Intimate Structure of the Brain, Human and Comparative," and those of Dr. John Dean "On the Gray Substance of the Medulla Oblongata and Trapezium."

BRAIN, Diseases of the. The diseases of the brain are considered as embracing, in addition to the affections seated in the cerebral sub- stance, or brain proper, those of the investing membranes or the meninges. The meningeal affections, that is, affections seated in the mem- branes, generally give rise to more or less dis- turbance of the functions of the brain, and not infrequently the disease extends from the men- inges to the cerebral substance. So, also, affections seated primarily in the brain proper often involve secondarily the investing mem- branes. Again, there are some diseases in which the cerebral substance and the meninges are simultaneously affected. Considering the diseases of the brain in this comprehensive sense, a convenient classification of them is the following: 1, cerebral congestion; 2, cerebral anæmia; 3, cerebral hæmorrhage; 4, inflam- matory affections; 5, structural lesions; 6, func- tional disorders. **I. CEREBRAL CONGESTION.** Here, as in other parts of the body, the name congestion denotes an overplus of blood (hy- peræmia), which is the result, on the one hand,

of an undue detention of blood, the quantity sent to the part being not necessarily greater, and perhaps even less than in health, or, on the other hand, of an undue supply of blood. An overplus of blood from detention is dis- tinguished as passive congestion, and the term active congestion denotes an undue determina- tion or supply of blood. In passive congestion the morbid accumulation is chiefly in the re- turning vessels or veins; in active congestion, the excess of blood is in the distributing ves- sels or arteries. In either form of congestion, the vessels of both the brain substance and the meninges are abnormally filled with blood. Active congestion of the brain may be caused by undue excitation of the emotional faculties of the mind. When this is the cause, the ex- cessive functional activity of the brain attracts to the head an undue quantity of arterial blood. Another cause is the abuse of alcoholic stimu- lants. Here, too, the exciting effect of alcohol upon the brain occasions a morbid afflux to the head. An increase of the muscular walls of the left ventricle of the heart is another cause of active congestion. This is apt to be a cause when the morbid muscular growth (hypertro- phy) is not compensated for by certain valvular lesions which obviate this effect. The active congestion under these circumstances is due to the blood being sent to the head in larger quantity and with greater force than in health. Active congestion of the brain, as regards its degree, varies from an amount which consti- tutes only a slight malady to an excessive de- termination of blood leading rapidly, or even suddenly, to death. Existing in a slight or moderate degree, it gives rise to diffused pain in the head, flushing of the face, and deficient or disturbed sleep. In a more marked degree, the headache is intense and accompanied with a sense of bursting, weight, or fulness; the sur- face of the head is hot; the face is deeply red- dened; the vessels of the eyes are injected; the arteries of the temple and neck pulsate strongly, and there is inability to sleep. Ac- tive or maniacal delirium is sometimes due to active congestion. Epileptiform convulsions are also, in some cases, attributed to this con- dition. A suddenly induced active congestion is among the different conditions giving rise to an apoplectic seizure which may prove speedily fatal. Apoplexy thus induced is distinguished as congestive apoplexy. The congestion may lead gradually to loss of consciousness, or coma, which may end in death. In some of the cases of insolation, or sunstroke, the only pathologi- cal condition found after death is cerebral con- gestion.—Active congestion of the brain may be diminished and often removed by appro- priate treatment. If dependent on mental ex- citement or the abuse of alcohol, the continued operation of these causes is of course, if pos- sible, to be prevented. In the rare cases of simple hypertrophy of the heart, that is, hy- pertrophy without valvular lesions, the abnor- mal power of the heart's action can be dimin-

ished by the regulation of diet and sedative remedies. In all cases, while the body should be well nourished, it is desirable to prevent or remove, by dietetic and other measures, that morbid condition of the blood known as plethora. Within the past few years a class of remedies—the bromides of potassium, ammonium, sodium, and calcium—have been introduced, which appear to diminish, by an effect upon the vessels, the amount of blood within the head. These remedies, at all events, have been found by experience to be useful in cases of cerebral congestion. In severe cases, characterized by active delirium or apoplectic coma, bloodletting will not only produce speedy relief, but, timely resorted to, it may rescue from impending death. If the symptoms and danger do not call for this potent measure, an active cathartic, especially croton oil, is promptly effective. Ligatures applied to the extremities may sometimes be substituted for bleeding. Cold applied to the head, in the form of either the douche or ice cap, is highly useful, and with these may be conjoined warm and stimulating applications to the extremities. Passive congestion, that is, an overplus of venous blood within the skull, is an effect of various causes which interfere with the return of blood from this part of the body. The pressure of the thyroid bodies when greatly enlarged (goitre), enlarged lymphatic glands, and tumors in the neck pressing on the jugular veins have this effect. Aneurismal or other tumors within the chest produce the same effect by pressure on the descending vena cava. A not infrequent cause belonging in this category is an obstruction to the passage of the blood into the right side of the heart, the obstruction being due to dilatation of the right auricle and ventricle, resulting from an obstacle to the circulation through the pulmonary organs, incident either to valvular lesions at the mitral orifice within the heart or to affections of the lungs themselves. Of the latter, pulmonary emphysema is the affection which especially leads to this result. Passive congestion from these causes, even when considerable, is often tolerated without great inconvenience. The face is more or less congested, and if the congestion be great, there may be lividity or blueness especially marked in the space over the lips intervening between the skin and mucous membrane, which is called the *prolabia*. As regards the symptoms referable to the brain, passive congestion occasions a dull pain, a sense of fulness, sluggishness of the perceptions and the intellectual faculties, and defective or disturbed sleep. Occurring as an effect of the causes which have been named, the condition admits of relief only so far as these causes can be diminished; and in many cases this is impracticable. There is another cause of passive congestion within the skull, incident to the fact that the brain is removed from atmospheric pressure owing to the solidity and occlusion of the bones of the cranium, and also to the fact that the brain is not compressi-

ble to much extent by the forces which govern the intracranial circulation. The cranium forming a closed box capable of resisting the pressure of the atmosphere, and the substance of the brain not yielding much to the pressure of blood within the vessels, it follows that whenever the supply of arterial blood is lessened, a suction force is exerted upon the blood in the veins, and more or less passive congestion of the brain is a consequence. Passive congestion, thus produced, is supposed to be a morbid element in affections which involve a diminished supply of blood to the head. The latter is an effect of impoverishment of the blood and of deficient power of the heart's action. This element is supposed to account for certain head symptoms occurring especially in children affected with cholera infantum. The blood in this affection is impoverished by profuse discharges from the stomach and bowels, and the heart's action becomes enfeebled thereby. These head symptoms, namely, morbid somnolency, semi-coma, and sometimes convulsions, were formerly considered to denote either inflammation of the meninges of the brain or serous effusion, affections which were embraced under the name *hydrocephalus*; hence, as simulating these conditions, the passive congestion produced in the manner just stated has been called the *hydrencephaloid* affection. The proper treatment of this affection embraces measures to restore the normal condition of the blood and the strength of the heart by alimentation, tonic remedies, and the judicious use of alcoholic stimulants. The treatment heretofore employed, based on the supposition of inflammation and effusion, was not only without good effect, but hurtful. It must be admitted that in cases of passive congestion from a deficiency of the supply of arterial blood, it is not certain how far the morbid phenomena are attributable to the congestion, and how far directly to the lack of the arterial blood. II. CEREBRAL ANÆMIA. The term anæmia is used in medical writing and conversation to denote a morbid condition of the blood, namely, a paucity of the red globules. This is the condition which is understood when the blood is said to be impoverished. The term also denotes a morbid deficiency of blood in any of the organs of the body. The name cerebral anæmia implies the latter sense of the term. The affection therefore consists in a morbid deficiency of blood within the skull. The anæmia from certain causes is general, that is, it affects the entire contents of the skull; or it may be limited to a portion of the brain, the latter being incident to causes affecting branches of the intracranial arteries. An effect of general cerebral anæmia, existing in a marked degree and suddenly induced, is the occurrence of syncope, fainting, or swooning. In this condition there is loss of consciousness, the face becomes deadly pale, and there are convulsive movements with gasping for breath, the person appearing to be upon the brink of dissolution. The condition, indeed, is

but a slight remove from death. Prolonged syncope may occasion sudden death; but in general, after a brief period, the circulation within the skull is restored, and consciousness returns. The cerebral anæmia in attacks of syncope is usually caused by a suddenly induced weakness of the heart's action, and this may be occasioned by various causes. A powerful mental emotion may so affect the action of the heart as to cause an attack of syncope. The rapid loss of blood is a cause. Assuming an erect posture after recumbency from disease is another cause. Impoverishment of the blood, or the morbid condition of this fluid known as anæmia, favors the operation of the different causes which, by enfeebling the action of the heart, gives rise to syncope. The measures to be employed in syncope are those which tend to increase the power of the heart's action, and determine a flow of blood to the head. The body should be immediately placed in a recumbent position, with the head low. The impression produced by dashing cold water in the face excites the action of the heart, and often arouses instantly the consciousness. When consciousness returns, an ethereal or alcoholic stimulant may be given, and repose for a time should be enjoined.—General cerebral anæmia, greater or less in degree, and more or less persisting, is referable to various causes, such as compression of the arteries going to the head, valvular lesions of the heart involving obstruction and regurgitation, and feebleness of the heart's action incident to different pathological conditions. The symptomatic effects are drowsiness, inability to sustain mental efforts, pain in the head, ringing in the ears, and sometimes mental hallucinations and illusions. With reference to their effects, it should be added that, as stated under the head of passive congestion of the brain, a morbid fulness of the veins within the skull, compensatory for a deficiency of the supply of arterial blood, is inferred from the fact of the contents of the cranium being removed from atmospheric pressure, together with the incompressibility of the cerebral substance; so that it is not certain how far these effects are due, on the one hand, to anæmia, or, on the other hand, to venous congestion.—Partial cerebral anæmia, that is, anæmia limited to a portion of the brain, is a morbid condition over which much light has been shed within the past few years by the researches of Kirkes, Virchow, and others. The arteries of the brain, beyond what is known as the circle of Willis, do not inosculate freely with each other. Hence, if an arterial branch be obstructed, the distribution of blood within the area of the cerebral substance supplied by the obstructed vessel is arrested for a time; and this defective supply of blood may lead to impaired nutrition, ending sometimes in the loss of vitality or a condition analogous to gangrene. Now, the arterial branches distributing blood to the different portions of the brain are liable to be obstructed, first, by the coagulation of blood with-

in them, and second, by a mass of fibrine or a detached vegetation either from the left cavities of the heart or from an artery situated between the heart and the brain. The obstructing substance in the first of these two modes is called a *thrombus*, and the morbid condition is known as *thrombosis*; in the second mode the obstructing substance is called an *embolus*, and the condition *embolism*; hence, a thrombus is a stationary, and an embolus a migratory plug. Thrombosis is apt to take place in the vessels within the skull, the coagulation of the fibrine of the blood being due to changes in the arteries which roughen the inner surface of these vessels. The fibrine is liable to coagulate on a roughened surface over which the blood flows. This is shown by the experiment of inserting a needle or a thread within a blood vessel; masses of fibrine collect upon the foreign substance. Embolism occurs oftener than thrombosis. Fibrine, a product of thrombosis in the left cavities of the heart, in one of the arteries leading from the heart to the head, or in an aneurismal sac, is liable to become separated by the force of the circulating blood, and it is then carried along with the current into the cerebral arteries, until at length it reaches a vessel too small to admit of its passage further onward; it is thus arrested in its course, and, becoming fixed, it obstructs the circulation in the branches given off beyond the point where it remains. Hence, a partial anæmia, which is more or less circumscribed according to the size of the obstructed artery. The same thing occurs when the embolus or plug is a morbid growth or a vegetation, instead of a mass of fibrine. Both thrombosis and embolism occur in various parts of the body, as well as within the skull. In the latter situation, the artery most likely to become obstructed, especially by an embolus, is the middle cerebral; and embolism is far more likely to take place in the left than in the right middle cerebral artery, because the embolus generally comes from the heart, and the most direct route from the latter organ to the brain through the arteries is on the left side. Thrombosis and embolism give rise to that form of paralysis distinguished as hemiplegia, namely, paralysis affecting the limbs and often the face on one side. The paralysis from embolism occurs suddenly, being a stroke of palsy, because the obstruction occurs suddenly. Often with the sudden palsy there is a temporary loss of consciousness, constituting an apoplectic seizure. This is one of several different morbid conditions giving rise to sudden coma or apoplexy. In a certain proportion of cases, the paralysis disappears completely after a time, the circulation being more or less slowly restored beyond the point of the obstruction. Recovery takes place if the circulation be restored before important changes in nutrition have resulted from the deficient supply of blood. Softening and even complete loss of vitality of cerebral substance within the space deprived of arterial blood

take place in some cases, and more or less hemiplegic paralysis then remains. Hemiplegia, either transient or persisting, is in like manner an effect of thrombosis. It is generally developed gradually, and is not so likely to give rise to sudden coma or apoplexy, because, the coagulation not taking place all at once, the obstruction occurs more or less gradually. III. CEREBRAL HÆMORRHAGE. Hæmorrhage within the cranium may take place, first, either into the substance of the brain or the spaces known as the ventricles, and second, between the membranes investing the brain. The name cerebral hæmorrhage is applied especially to an extravasation in the two former of these situations. Situated between the membranes, it is distinguished as meningeal hæmorrhage. Hæmorrhage very rarely takes place primarily within the ventricles of the brain; when blood is found here, the seat of the extravasation is generally in the cerebral substance, and the blood has thence made its way into the ventricles. Hæmorrhage is the most frequent of the several morbid conditions giving rise to the sudden loss of consciousness which characterizes an apoplectic attack. In the great majority of the cases of apoplexy caused by this condition, the hæmorrhage takes place in the substance of the brain. The extravasation is seated in either the corpus striatum or the thalamus opticus much oftener than in any other of the anatomical divisions of the brain; it may, however, occur in any portion of the cerebral substance. The quantity of blood which escapes varies greatly in different cases. If very large, death may occur within a few hours. Sudden or almost instantaneous death, however, is very rarely if ever caused by cerebral hæmorrhage. If the extravasation be small, the patient emerges after some hours from the coma or apoplectic state; the clot may subsequently be absorbed, and recovery may take place, with more or less permanent injury of the brain. An apoplectic attack dependent on hæmorrhage into the substance of the brain is almost always accompanied by paralysis of the muscles of the limbs, and generally also of certain of the muscles of the face on one side of the body (hemiplegia). This is always a concomitant of an extravasation into the corpus striatum, or the motor tract of the fibres of the brain. The paralysis of the limbs, and generally also of the face, is on the side opposite to the cerebral hemisphere in which the hæmorrhage is seated. In some cases in which the extravasation is small, or in which it takes place slowly, hemiplegia, without apoplexy, is the effect. Hemiplegia, in the cases of apoplexy dependent on hæmorrhage into the substance of the brain, persists after the apoplectic state disappears; and in general this form of paralysis in a greater or less degree continues permanently, even when the extravasated blood has been absorbed. After an apoplectic attack from cerebral hæmorrhage, the mental faculties generally become more or less impaired. The degree of impairment will

depend on the amount of injury which is the immediate effect of the hæmorrhage, and on the disorganization due to the inflammation excited by the presence of the clot. It is also to a certain degree dependent on the diminished exercise of the mental faculties which is usual after an attack of apoplexy. Cerebral hæmorrhage is generally a consequence of disease of the arteries of the brain. They are liable to become instantaneously fatty, and to be rendered brittle by the deposit of calcareous matter. Hence, either with or without some unusual tension, such as is caused by violent muscular efforts or intense mental excitement, they give way, and extravasation occurs. Another condition favoring rupture is the formation of minute dilations, which are called miliary aneurisms. These changes in the arteries rarely take place prior to middle age; hence, apoplexy and hemiplegia dependent on cerebral hæmorrhage seldom occur in youth.—During an attack of apoplexy dependent on extravasation of blood, little is to be done in the way of treatment beyond keeping the body of the patient quiet, with the head raised, removing all articles of clothing which make pressure on the neck or chest, and applying cold to the head. Bleeding under these circumstances, which was formerly resorted to, is now rarely employed. An active cathartic is generally given. If the patient emerge from the comatose state, the objects of treatment are the promotion of absorption of the clot, the prevention of a repetition of the hæmorrhage, and the recovery as far as practicable from the paralysis. As the changes in the vessels which occasioned the hæmorrhage continue, its recurrence is always to be apprehended. Yet not unfrequently life continues for many years and a second hæmorrhage does not occur. It is important to add that cerebral hæmorrhage is seldom preceded by premonitory symptoms. Hence, in general, vertigo, ringing in the ears, and other symptoms which naturally lead persons to anticipate an attack of apoplexy, are not to be thus interpreted. Much relief from needless apprehensions may often be afforded by recollecting the statement just made.—Hæmorrhage situated between the membranes of the brain, or meningeal hæmorrhage, is extremely infrequent in comparison with extravasation in the cerebral substance. This statement is especially true if cases in which meningeal hæmorrhage is attributable to injuries received on the skull be excluded. The latter are distinguished as traumatic cases. Excluding these, the seat of the hæmorrhage is generally beneath the arachnoid membrane. The blood escaping in this situation may be more or less diffused over the surface of the brain, remaining beneath the arachnoid membrane; or this delicate membrane may be ruptured, and then the blood is diffused over the brain within the arachnoid cavity, between the arachnoid and the dura mater. A small quantity of blood in this situation may not give rise to serious results, and it may even

be unattended with any violent symptoms referable to the head. A considerable hæmorrhage here, however, occasions insensibility or coma, which is developed suddenly or gradually, according to the rapidity as well as the amount of the hæmorrhage. The patient may emerge from this coma, and if the hæmorrhage recur, as is sometimes the case, the coma is again renewed. Usually, owing to the diffusion of the blood over the surface of the brain, there is not hemiplegia, as in cerebral hæmorrhage. Death may be expected to take place if the amount of the hæmorrhage be sufficient to occasion a prolonged or repeatedly recurring coma.—A form of meningeal hæmorrhage occurring independently of traumatic causes is known as hæmatoma of the dura mater. In this form, the blood is under the dura mater, and is contained within oval fibrinous sacs several inches in diameter and three or four inches thick. These are generally found on the upper surface of both hemispheres of the brain. The fibrinous sacs are supposed to denote inflammation. This affection occurs in children and in aged persons; but it is rare, and not determinable with certainty during life. Sooner or later it ends fatally, after having induced diminished power of motion of the limbs on both sides and stupor, which at length eventuates in coma.

IV. INFLAMMATORY AFFECTIONS. In the comprehensive sense of the phrase "diseases of the brain," inflammatory affections may be seated in either the membranes or the cerebral substance. Their primary seat is much oftener in the former than in the latter. Of the membranes investing the brain, the dura mater is very rarely inflamed. An inflammation seated in this, the outer of the cerebral membranes, or the meninges, is almost always limited to a circumscribed space, and is produced either by an injury of the head (traumatic), or by an extension of disease from a contiguous part of the skull. An idiopathic or spontaneous primary inflammation of this membrane perhaps never occurs, if the affection called hæmatoma of the dura mater be excluded. The term cerebral meningitis denotes inflammation of the membranes or meninges of the brain; but the term is considered as embracing only inflammatory affections seated in the pia mater and arachnoid membrane. Inflammation affects these two membranes conjointly; that is, whether the point of departure be in the one or the other, both are involved. Cerebral meningitis is acute, subacute, or chronic. In addition, a variety of the disease is called tuberculous meningitis. The term simple meningitis is used to distinguish an ordinary inflammation from the variety called tuberculous. Exclusive of traumatic cases, that is, those in which the disease is produced by injury from falls or blows, causes of simple acute meningitis are insolation, or exposure to great heat, and excessive indulgence in alcoholic stimulants. These causes are chiefly operative when adults are affected with the disease. Acute inflammation from other

causes than these, and from injuries of the head, occurs oftener in children than after adult age. In children it is sometimes developed in the course of scarlet fever, erysipelas, and measles. But simple acute meningitis, irrespective of traumatic cases, is extremely rare. The symptoms of acute meningitis are at the beginning essentially the same as in active cerebral congestion; and this, indeed, is the pathological condition. The prominent local symptoms are intense, diffused pain in the head, flushing of the face, notable intolerance of light and sounds, an increase of the sensibility of the surface of the body (hyperæsthesia), throbbing of the arteries of the neck and head, and delirium, which is often active or violent. Hallucinations, as well as delusions, enter into the delirium. With these local symptoms, there is symptomatic fever, as shown by frequency of the pulse, increased heat of the skin, and, more especially, augmented temperature of the body as denoted by the thermometer placed in the armpit. Convulsions sometimes occur. Other symptoms denoting constitutional disturbance are loss of appetite, often vomiting, constipation, disturbed rhythm of respiration, and more or less debility, except when the patient is under the excitement of delirious volitions. These symptoms belong to the first stage, or the stage of excitement, the duration of which varies from a few hours to several days. The symptoms which distinguish the second stage are due mainly to compression of the brain by the inflammatory products, lymph, serum, and pus, which are situated for the most part beneath the arachnoid membrane. These symptoms are somnolence ending in coma, paralysis of certain of the facial muscles, and sometimes of the muscles of the limbs, on one side, dilatation of the pupils, slowness and irregularity of the pulse, &c. These symptoms generally denote a fatal ending. This stage is distinguished as the stage of compression and of collapse. Simple acute meningitis is always a disease involving great danger to life. A very large proportion of cases end fatally. Life may be destroyed speedily, sometimes within a few hours. In most fatal cases the duration of the disease does not extend beyond a week. The measures of treatment which are appropriate to the first stage are: bloodletting by venesection and leeching, if there be no circumstances to contraindicate the abstraction of blood; cold applied to the head by means either of cloths wetted at short intervals in ice water, the cold douche, or the ice cap; and active purgation. As remedies which appear to diminish the blood within the skull, the bromides are to be recommended, clinical experience having shown their utility. In the second stage, the great object of treatment is to promote the absorption of the morbid products. Mercury and the iodide of potassium are prescribed for this object. Blisters may be employed for the same end. Alimentation, to an extent corresponding with the ability to take and digest nutritious food,

enters into the treatment in the second stage.—Acute cerebral meningitis may be associated with an acute inflammation of the corresponding membranes of the spinal cord. The affection is then called cerebro-spinal meningitis. This characterizes a remarkable and extremely fatal epidemic disease, generally known by the name epidemic cerebro-spinal meningitis. A subacute simple cerebral meningitis, in which the inflammation does not become chronic, is infrequent; but cases occur, chiefly in children. The symptoms in the stage of excitement are the same in character as in the acute disease, but notably less marked or intense. The symptoms due to compression may be developed after a slight or moderate headache, intolerance of light and sounds, febrile movement, &c.; and a fatal coma may be caused by an abundant serous effusion. The treatment in these cases relates chiefly to the absorption of serous effusion.—Subacute inflammation of the meninges of the brain is generally presented as a chronic affection, and is called chronic cerebral meningitis. The local symptoms are pain in the head, muscular weakness, undue disposition to sleep, change in the mental disposition or character, more or less impairment of the intellectual faculties, paralysis affecting sometimes certain of the facial nerves, and in some cases the two limbs on one side; and at length, in the great majority of cases, a fatal termination occurs, preceded by great exhaustion and frequently by coma. This affection may follow acute meningitis, but in general the inflammation is subacute from the outset. It is often latent; that is, it is not declared by well marked symptoms pointing to inflammation within the skull; and it is, therefore, liable to be confounded with other affections. Mental irritability and dulness of the faculties of the mind may for some time be the only symptomatic characters referable to the head. Moreover, it is by no means always easy to discriminate by the symptoms this affection from softening and other cerebral lesions. The duration of the disease is often long, not infrequently lasting many months, and even years. Sooner or later, it ends generally in death. The causes are usually obscure. Happily it is rare. There is not much prospect of benefit from drugs; but certain remedies, namely, mercury and iodine, may be tried. The great object of treatment is to maintain nutrition and thus enable the system to tolerate the disease as long as possible.—In tuberculous meningitis, the inflammation of the meninges is referable to the presence of tubercles or miliary granulations. These morbid products are seated at the base of the brain, and hence the inflammation is limited to or most marked at the base; whereas, in simple meningitis, the upper portion or convexity of the brain is chiefly or especially the seat of the inflammation. The ventricles of the brain in this affection are apt to contain liquid in more or less abundance, and hence formerly the affection was called

acute hydrocephalus. The affection is vastly more frequent in infancy and childhood than in after periods of life, but it occurs at all ages. It is almost invariably associated with tubercles in other organs, and especially in the lungs. In general, the development of this affection takes place gradually. For some weeks or months before the disease becomes declared, children generally show symptoms of ill health, namely, loss of appetite, indisposition to exercise, and more or less emaciation. Especially a mental change is noticeable, consisting in irritability of temper and dulness of the faculties of the mind. These symptoms probably relate to the tuberculous disease, and precede the acute inflammation. The latter is characterized by headache, generally intense and persisting, accompanied often by persistent vomiting; there is usually intolerance of light and sound; the face is apt to be flushed in paroxysms; there is fever, as shown by the pulse and temperature of the body. These symptoms continue for a period ranging from a few days to a fortnight; and then a change occurs which is attributable mainly to the presence of the inflammatory products, lymph, pus, and serous effusion. The pulse is now diminished in frequency, and it may fall considerably below the healthy standard; it is apt also to be irregular and faltering. The respiration is altered in rhythm, becoming irregular and suspirious. The pupils are dilated. The perceptions are blunted; the patient lies most of the time in a state of somnolency. Lancing pains in the head are, however, felt from time to time, giving rise in infants to a sudden sharp cry which is quite distinctive. The temperature of the body may now fall below the minimum of health. The vomiting becomes less, or it may cease. The bowels are constipated, and the abdomen depressed. Convulsions, which sometimes occur before, are not infrequent after this change in the symptoms has taken place. Strabismus or squinting is common. Paralysis of the muscles of the face or of the limbs on one side is frequent. At length vision is lost; the somnolency eventuates in coma, and, under these circumstances, the affection ends fatally. The tendency to death is such, that when this affection is considered to exist, recovery is a ground for the rational presumption that the affection was not really present, but simulated. In children, it is liable to be confounded with typhoid fever, and with a condition already referred to, namely, cerebral anæmia incident to disorder of the digestive system. Moreover, it is not always easy to discriminate it from a simple acute meningitis. The iodide of potassium has been of late years chiefly relied upon in the treatment of tuberculous meningitis. Its efficacy, however, in any case is questionable; and there are no remedies at present known which can be given with any expectation of effecting a cure. The only hope, in cases which seem to present the evidence of existence of this affection, is that the diagnosis

may be incorrect. Blisters, active purgatives, and other debilitating and perturbatory measures of treatment are not only not indicated, but they increase suffering and hasten the fatal termination.—Inflammation either limited to or having its point of departure in the substance of the brain is known as *cerebritis*. As already stated, the substance of the brain is more or less involved in meningitis. Independently of the latter, cerebritis is rare; and if the cases be excluded in which inflammation of the substance of the brain is secondary to tumors or to the presence of a clot, or is incident to injuries, it is extremely infrequent. In fact, a primary or idiopathic cerebritis is one of the rarest of affections. Its infrequency has been rendered more evident within late years by the knowledge which has been acquired of necrobiosis, or softening from embolism and thrombosis, to which reference has been made under the head of anæmia of the brain. Cases of the latter kind of softening were formerly considered as cases of cerebritis. The presence of blood giving rise to "red softening" has been considered as evidence of inflammation; but this is now held to be an error. Softening from defective nutrition may be red as well as white. The positive evidence of cerebritis is the presence in the cerebral substance of the inflammatory products, fibrine or pus. Cerebritis, as a primary or idiopathic affection, is always circumscribed, or confined to a limited space. It occurs chiefly in the gray matter of the brain, that is, in the cortical portion of the corpus striatum. If pus be present, it is called abscess of the brain. The symptoms and the duration in different cases entitle it to be considered either an acute or a chronic affection. If acute, pain in the head is more or less prominent as a symptom, and there are present the symptoms denoting hyperæmia or cerebral congestion. Spasms of certain muscles, either tonic or clonic, may occur, and sometimes there are general convulsions. Subsequently, when the inflamed portion becomes disorganized, that is, when softening or the formation of an abscess ensues, paralysis generally occurs. The paralysis is developed gradually, and in different cases different muscles are affected. In most cases the muscles of the face are paralyzed in a greater or less degree, and hemiplegia is common. The mental faculties become impaired, as denoted first by a morbid emotional susceptibility, and afterward by loss of memory and inability to carry on processes of ratiocination. At length mental imbecility or dementia is likely to occur. Chronic cerebritis, or abscess of the brain, presents the same symptoms which belong to the acute form after softening or suppuration has taken place. The points of distinction, as regards the symptomatology, between the acute and chronic affection, relate to the presence of symptoms denoting more distinctly an inflammatory condition in the former, and a longer duration of the disease in the latter. Chronic cerebritis

or abscess is not easily discriminated during life from other affections which are to be noticed presently under the head of structural lesions. Cerebritis, both acute and chronic, is generally secondary to injuries of the skull, or to disease of the bones of the head. It is apt to follow caries of the petrous portion of the temporal bone, the latter being connected with inflammation of the internal ear. It may fairly be doubted if recovery ever takes place. Chronic cerebritis, however, leading to softening or abscess, is not incompatible with a long duration of life, death at length occurring, perhaps, in consequence of some intercurrent disease. The indications for treatment relate to palliative measures, and those which enable the system to tolerate the affection as long as possible. V. STRUCTURAL LESIONS. Lesions involving palpable changes in structure, affecting the brain more or less extensively, and with different degrees of damage, are of various kinds. Important lesions have already been referred to, namely, softening from defective nutrition, and either inflammatory softening or suppuration. Another lesion, probably of inflammatory origin, is induration or sclerosis. Other lesions are the morbid growths or deposits which constitute the different tumors of the brain. These various structural changes have certain symptoms in common, and in medical practice it is by no means easy always to differentiate them. Induration of the brain, or sclerosis, may be confined to one situation which is more or less extensive, or it affects small circumscribed portions which are more or less numerous. The former is distinguished as diffused, and the latter as multiple cerebral sclerosis. The diffused form most frequently occurs in children, although it may occur at any period of life. It is a pathological condition which in certain cases affords an explanation of idiocy. It leads to paralysis, and consequently to an arrest of development of certain of the voluntary muscles. It may lead to contractions and deformities in consequence of the extensor muscles being more paralyzed than the flexors, or *vice versa*; the muscles which are the least paralyzed contracting for want of the normal antagonism afforded by those in which the paralysis is greatest. In multiple cerebral sclerosis, hardened nodules, varying in size from a cherry stone to a small walnut, and more or less numerous, are scattered throughout the brain, generally being found in the white substance. They are produced by a morbid growth of the connective tissue, that is, the tissue which unites the nervous fibres and cells together with the blood vessels. This tissue is now known by the name neuroglia. Its morbid growth is supposed to be a consequence of chronic inflammation. The hypertrophied neuroglia induces by pressure atrophy of the nervous structure, and consequently impairment of function in the sclerosed portions. The causes are obscure; but circumstances connected with age have a

marked influence on the causation. It very rarely occurs in persons under 50 years of age. Muscular tremor, beginning slightly in a few muscles and gradually increasing and extending, is one of the most characteristic of the symptoms. After a time the limbs and sometimes the head are involved in the tremor, which at first can be arrested by volitional efforts, and exists only in the waking hours, but at length continues in spite of the will and during sleep. Paralysis greater or less in degree follows the tremor. The name *paralysis agitans*, or shaking palsy, has been applied to these cases. Prior to and with these symptoms lancinating pains in the head are common. Distortion of the limbs may occur from the paralysis affecting certain muscles (generally the flexors) more than others. Certain cases present remarkable peculiarities in the mode of progression. Thus some patients are able to run forward rapidly when they cannot walk, and are obliged to support themselves by clinging to some solid body in order to prevent themselves from falling when they stop. In other cases patients are able to walk backward, but not forward. The course of this affection is usually slowly progressive; yet in some cases it remains stationary. Existing in a marked degree, it may not prevent long life. A cure is not to be expected; but improvement is sometimes effected by the chloride of barium, the phosphide of zinc, strychnia, and electricity. The tolerance and duration of life are promoted by measures which tend to improve the general health, and maintain it at the highest possible point. Multiple sclerosis of the brain is not infrequently associated with a similar affection of the spinal cord.—Tumors within the cranium have the different anatomical characters which belong to tumors in other situations. The most frequent are those distinguished as cancerous, tuberculous, and syphilitic. Others which are comparatively rare are aneurismal, fibro-plastic, and parasitic, the latter consisting of the cysticercous or hydatids. There are still others which are occasionally found. The different tumors vary in number, size, and situation. There may be but one tumor, or the number may be great; in the latter case, they are usually small. They may be very small, not exceeding the size of a pin's head, or they may be as large as an orange, or even larger. They may be seated in different portions of the cerebral substance, or they may have their point of departure from the membranes, and sometimes from the bony structure. They produce morbid effects, or symptoms, by pressure on the cerebral structure together with the nerves within the skull, and by giving rise frequently to circumscribed inflammation, which may lead to either induration or softening. The more grave of these morbid effects are paralysis affecting different parts, and more or less impairment of the intellectual faculties. Convulsions belong among their effects. They are

generally accompanied with pain localized within a circumscribed space, and vertigo is not uncommon. The system suffers in proportion to the amount of the injury which the brain receives, and frequently also from the general condition with which the local affection is associated. The latter applies especially to cancerous and tubercular tumors. Sooner or later, as a rule, they destroy life. The local symptoms which denote especially tumor within the skull are a localized persistent pain, and the occurrence of paralysis affecting different parts successively, after intervals of varying duration. Frequently, but not always, these points suffice for a positive diagnosis of tumor of some kind. The associated circumstances, such as tuberculous or cancerous disease elsewhere, or the fact of syphilis having existed, enable the physician to decide with considerable confidence on the nature of the tumor. Moreover, its situation may frequently be inferred from the parts which are paralyzed, together with the amount and kind of mental disturbance. With our present knowledge, curative treatment is limited exclusively to syphilitic tumors. The effect of anti-syphilitic medication, where the symptoms denote the existence of tumor of this kind, is sometimes remarkable. It is, therefore, highly important that the physician should know the grounds for supposing the tumor to be syphilitic in character. Mercury and the iodide of potassium are the remedies indicated if the tumor be syphilitic.—A curious morbid condition, incident to different structural lesions, and sometimes occurring as a functional affection, may be noticed in this connection. Reference is had to the condition now generally known as *aphasia*. This term signifies loss of speech, not from any affection of the organs concerned in phonation, but from either an inability to remember words, or a want of power to coördinate the movements involved in speech. As thus defined, aphasia is to be distinguished from aphonia, the latter term denoting loss of voice from an affection of the vocal apparatus, or from a paralysis affecting the muscles concerned in phonation. In aphasia the vocal organs are unaffected, and the patient has voluntary control over the muscles of the larynx and mouth. Nor is aphasia to be confounded with loss of speech in consequence of dementia or mental imbecility. Patients affected with aphasia understand what is said to them, and they are able to read; but the ability to express their ideas in language is lost or more or less impaired. A marked difference exists among different cases of aphasia. In some, while the patient is unable to speak, there is the ability to communicate their ideas by writing; in other cases, the patient can neither speak nor write. Hence, according to this difference, aphasia is of two kinds, namely, amnesic and ataxic. In amnesic aphasia both speaking and writing are lost or impaired; in ataxic aphasia speech is lost, but the ability to write remains.

In the first kind, the difficulty consists in the loss of the memory of words; in the second kind, the difficulty seems to lie in the inability to coördinate the movements necessary to speech, the memory of words being preserved. Aphasia of either kind may be complete, when speech is entirely lost, or there is more or less impairment of the power of speaking. Frequently the vocabulary of the patient is limited to a few words, perhaps a single word, uttered whenever an attempt is made to speak. Thus, patients may be able to say only *yes* or *no*, and this is said in answer to any question. It is not easy to determine, in cases of aphasia, to what extent, if at all, the mental powers are affected; but it is certain that complete aphasia may exist while the faculties of the mind, aside from speech, are not materially affected. As already stated, aphasia may be incidental to different structural lesions, namely, hæmorrhage into the substance of the brain, softening from embolism or thrombosis, cerebritis, induration, and tumors. Generally it is associated with hemiplegia, and the paralysis is usually on the right side, the local affection of the brain being situated in the left hemisphere. And now a remarkable fact is to be stated: the lesion giving rise to aphasia in the great majority of cases is seated in a particular portion of the left cerebral hemisphere, namely, the posterior part of the third convolution of the anterior lobe of the cerebrum. This fact has led to the supposition that the portion of the left hemisphere first named is to be regarded as the seat of the faculty of language; but, as opposed to this, although the rule is as stated, there are some exceptions to it. Evidently, if the faculty of speech depended on the integrity of a particular part of the brain, that part should be affected in all cases of aphasia. Aphasia is generally a symptom of a lesion of some kind; and it is then almost always persistent. There may, however, be some improvement as regards speech, although recovery do not take place. In some cases it is apparently dependent on a functional condition, and it is then recovered from. Aside from the measures of treatment which may be indicated by the nature of the lesion with which it is associated, or the circumstances connected with it when it is functional, efforts to speak on the part of the patient should be enjoined. Something may be accomplished by systematic endeavors to recover the memory of words or the power of coördinating the movements involved in speaking. VI. FUNCTIONAL DISORDERS. The term functional disorder, as now used, denotes a morbid disturbance of functions taking place independently of either inflammation or any palpable alteration of structure. It is convenient to arrange certain affections under this head, notwithstanding it is doubtless true that every so-called functional disorder involves some structural change. Admitting this, a disorder is to be distinguished as functional if it be non-inflammatory, and the circumstances are such as to exclude all the different varieties

of structural change which morbid anatomy, in the present state of our knowledge, recognizes. With this definition, what are the functional disorders referable to the brain? The different kinds of mental derangement—mania, monomania, melancholia, dementia—may be considered as varieties of functional disorder of the brain. (See INSANITY.) In this statement it is implied that, in a certain sense, the normal intellectual and emotional faculties are to be regarded in the light of cerebral functions. We may assume such to be the fact, without any skepticism as to the existence of the soul, in which consists personality, and which will survive the body, albeit it is in the order of Providence that in the present life the exercise of the mental faculties, and even the consciousness of being, are dependent on the physical organism. The phenomena embraced under the name delirium, and the more or less complete loss of consciousness and volition called coma, are evidences of functional disorder of the brain occurring in connection with various diseases, without involving either cerebral lesions or inflammation. These forms of functional disorder occur in fevers, and also in various local affections. Under these circumstances the brain is functionally disordered in consequence of morbid conditions of the blood. Thus the delirium of typhus and typhoid fever is referable to those blood changes, imperfectly understood as yet, in which consists the essential pathology of these diseases; and the coma occasioned by certain diseases of the kidneys is an effect of an accumulation of urea in the blood, or uræmia. Various remedies, by a toxic effect on the brain, may give rise to functional delirium or coma. This is true of opium, belladonna, and other narcotics, chloroform, &c. The phenomena of drunkenness denote functional disorder due to the presence of alcohol in the blood which circulates within the skull. There are certain nervous affections distinguished as functional, and called the *neuroses*, in which the functions of the brain are perverted or impaired; examples are epilepsy, hysteria, hydrophobia, and ecstasy. Finally, irrespective of all the foregoing affections, the faculties of the mind are often affected, but not sufficiently to constitute either coma, delirium, or insanity, and certain cerebral symptoms occur as results of functional disorder of the brain. Mental depression, irritability of temper, painful sensations referable to the head, vertigo, and wakefulness are manifestations of functional disorder due to over-exercise or excitation of the mental powers, intellectual or emotional, prolonged anxiety, impoverishment of the blood (anæmia), and probably by various morbid conditions of the latter incident to disordered assimilation, the retention of matters which should be eliminated by the different excretory organs, or the introduction of morbid principles by means of the air. The relations of functional disorder of the brain to the happiness of individuals and the welfare of mankind

is a subject of much importance, to which only this simple reference is here appropriate.

BRAINARD, Daniel, an American surgeon, born at Whitesboro, Oneida co., N. Y., May 15, 1812, died in Chicago, Oct. 10, 1866. He took the degree of M. D. at the Jefferson medical college, Philadelphia, in 1834. In the spring of 1836 he delivered a course of lectures on anatomy and physiology at the Oneida institute, and in the latter part of the same year removed to Chicago. In 1839-'41 he visited Europe for professional improvement, and was soon afterward appointed professor of anatomy in the university of St. Louis. In 1843 he took part in the organization of the Rush medical college at Chicago, in which he was professor of surgery during the remainder of his life. His reputation, otherwise than as a surgical practitioner, in which respect he held perhaps the most prominent position in the northwest, rests upon his advocacy of subcutaneous perforation of ununited bones for the cure of false joint, and the treatment of serpent bites and other poisoned wounds or unhealthy inflammations by means of alterative injections. Besides numerous papers in the "American Journal of the Medical Sciences," and other periodicals, he published an essay "On the Treatment of Ununited Fractures and Deformities," the prize essay of the American medical association for 1854. For some years he was engaged upon an extensive surgical work, which was unfinished at his death.

BRAINARD, John Gardiner Calkins, an American poet, born at New London, Conn., Oct. 21, 1796, died there, Sept. 26, 1828. He graduated at Yale college in 1815, and began the study of law, but soon abandoned it to become editor of the "Connecticut Mirror," at Hartford. He published many poetical compositions in this journal, usually in the form of ballads. A volume of his poems was published in New York in 1825, and after his death an enlarged edition appeared in 1832, with the title "Literary Remains." A third edition was published in 1842 at Hartford, with a memoir by John G. Whittier, the Quaker poet.

BRAINE-L'ALLEUD, or **Braine-la-Lèude**, a town of Belgium, in the district of Nivelles, province of South Brabant, 10 m. S. of Brussels; pop. about 5,000. Agriculture is the principal occupation, but there are manufactures of cotton goods, leather, glass, and starch. A mound surmounted by a colossal lion commemorates the battle of Waterloo, which was partly fought in this commune.

BRAINE-LE-COMTE, a town of Belgium, province of Hainaut, on the Senne, 13 m. N. N. E. of Mons; pop. in 1869, 6,464. It contains a fine château, and the handsome church of St. Gery, with a richly carved altarpiece. It is famous for the cultivation of flax and the manufacture of Brussels lace. There are also other branches of industry. Count Baldwin in the 12th century bought the ground from the monks of Mons.

BRAINERD, David, an American missionary, born at Haddam, Conn., April 20, 1718, died at Northampton, Mass., Oct. 9, 1747. In 1739 he entered Yale college to prepare himself for the ministry, but was expelled in 1742, for having said of one of the tutors that he had no more of the grace of God than a chair. He was licensed the same year as a preacher, and received an appointment from the society for the propagation of Christian knowledge, as missionary among the Indians near Stockbridge, Mass. He was ordained in 1744, and went on a mission to the Indians at the forks of the Delaware in Pennsylvania, making two visits to the Indians of the Susquehanna. He met with little success until, after a year, he went to reside among those at Crossweckung near Newark, N. J. Here he is said to have produced a great change among the savages, and to have baptized 78, of whom 38 were adults. In 1747 he went to Northampton, Mass., where he died after a short stay in the family of Jonathan Edwards, by whom his biography was soon afterward written. A new edition of this work, together with his journals, *Mirabilia Dei apud Indicos*, and "Grace Displayed," was published in 1822.

BRAINTREE, a town of Norfolk county, Massachusetts, on the Old Colony and Newport, and South Shore railroads, 10 m. S. of Boston; pop. in 1870, 3,948. The manufacture of boots and shoes is extensively carried on; there are also manufactories of linen, woollens, paper, machinery, carriages, &c. John Adams and John Quincy Adams, presidents of the United States, were born in Braintree, in the part which in 1792 was set off as the town of Quincy, where the Adams family now have their summer residence. John Hancock was also born in the same town.

BRAKE, or **Braake**, a town of Germany, in the grand duchy of Oldenburg, on the left bank of the Weser, 20 m. N. W. of Bremen; pop. 4,077. It carries on considerable trade and ship building, having been a free port since 1834. Until the foundation of Bremerhafen in 1827, Brake was the actual port of Bremen, as vessels of considerable size could ascend the Weser to this point. About 500 vessels a year still arrive at Brake.

BRAKE, or **Break**, an instrument for retarding or arresting by friction the motion of wheels. When applied to a hoisting reel, it consists of a flexible band of iron bent around a wheel; one end of the band is made fast to the frame of the reel, and the other end is attached to the small arm of a lever, the whole being so arranged that a slight pull on a rope attached to the long arm of the lever tightens the iron band on the rim of the wheel, which is arrested by the consequent friction. A carriage brake in its primitive form consists of a beam placed crosswise under the frame of the vehicle, and supporting two curved blocks of wood, one at each end, which may be firmly pressed against the periphery of the wheels. The brake was

formerly an instrument of little importance, and prior to 1835 only one patent for a brake was granted in the United States. Since the adoption of high speed upon railroads the subject of brakes has become one of great interest. There are two kinds used on railroad carriages, the ordinary brake for stopping the train at stations, and the safety brake, which may be applied instantaneously to the wheels of all the carriages on a train for the purpose of bringing it to a sudden halt. The ordinary car brake consists of a friction block, a lever, a chain and rod for moving the lever, and a windlass upon the platform of the car. The general plan and principle of action are represented in fig. 1,

FIG. 1.

where *a* is the wheel turned by the brakeman, *s* the shaft around which the chain *c* is wound, forming the windlass, which by the action of simple levers draws the friction blocks *b*, fig. 2, against the periphery of the wheel. The application may be made in various ways.—Of the safety brakes there are several, but they may all be divided into three kinds: the first, in which the power is derived from a coiled spring; a second, in which it is derived from compressed air contained in a cylinder; and a third, in which electro-magnetism is the motive power. All these brakes employ

FIG. 2.

the same friction block and leverage, which is connected with the windlass ordinarily turned by the brakeman. What is known as the Creamer brake, which is extensively used in the United States, employs a spiral spring as the motive power. This spring is coiled in a drum, which is placed upon the platform of the car, and through the drum passes the shaft, which is turned by the brakeman. The general arrangement is represented in fig. 3,

FIG. 3.

l, which on being pulled by the cord liberates the spring, causing it to exert its force through the chain and lever upon the friction block, drawing it against the wheel.—The compressed air brake used in the United States

is known as the Westinghouse air brake, and is made at Pittsburgh, Penn. Under each carriage there is placed a cylinder, fig. 4, 18 or 20 inches in length and about 8 inches in diameter, which is connected by metallic pipes and india-rubber tubing with a reservoir of compressed air attached to the engine, and which by a force pump receives a pressure of about 60 lbs. to the square inch. When the engineer wishes to bring the train to a sudden stop, he opens a valve leading from the air chamber to the various cylinders under the carriages. The air rushes through the tubes, and, pressing upon the piston heads, moves them. By a connection with the piston rods the friction blocks are forced against the wheels simultaneously throughout the whole train.—An electric brake, devised by M. Achard of Paris, is described in President Barnard's "Report of the Paris Exposition of 1867," but it does not possess the practical advantages of either the Creamer or the Westinghouse brake.

FIG. 4.

BRAKENBURG, Regner, a Dutch painter, born at Haarlem about 1650, died there in 1702. He selected his subjects frequently from low life, which he illustrated with great truthfulness and humor. His pictures are numerous in France and the Low Countries.

BRAMAH, Joseph, an English engineer, born at Stainborough, Yorkshire, April 13, 1749, died Dec. 9, 1814. He showed at an early age a remarkable mechanical ingenuity, was apprenticed to a carpenter, and subsequently removed to London, where he worked for a cabinetmaker, and afterward set up in the same business for himself. In 1784 he took out a patent for his widely renowned locks. Among many other inventions, he devised the hydraulic press, which is used not only in the ordinary mode of a press, but also for lifting enormous weights. He was the inventor of a mode of printing the number and date of bank notes used in the bank of England, by which the services of 100 clerks out of 120 were dispensed with. In 1812 he secured a patent for the construction of main pipes through the principal streets of a city, of sufficient strength to withstand great pressure to be applied by force pumps. The object of this invention was to provide the means of extinguishing fires without the aid of a fire engine.

BRAMANTE D'URBINO, an Italian architect, whose real name was DONATO LAZZARI, born at Monte Asdrualdo, near Fumignano, in 1444, died in Rome in 1514. At an early age he was placed as pupil with Fra Bartolommeo, and several of his pictures are still preserved at Milan. Having gone to Rome, he executed a few frescoes, but his taste was wholly for architecture, and his study of the antiquities of the city confirmed this bias. His erection of

the cloister of the convent della Pace obtained him the patronage of Pope Alexander VI., for whom he executed the Cancellaria, or palace of the chancery. Julius II. afterward employed him to draw plans for the Belvedere. He also built the oratory or temple in the cloister of San Pietro in Montorio. He was the author of the original design of St. Peter's, and had completed the four great piers that support the dome when he died. His plan was not adhered to by Michel Angelo, who completed the edifice. Bramante was the uncle of Raphael.

BRAMBANAN, a small native town of Java, in the sultanate of Jokjokarta, and about 10 m.

The Great Temple at Brambanan.

distant from the capital of that state. The name signifies "abode of Brahma;" and in its immediate vicinity are the remains of several magnificent temples, which were evidently devoted to the worship of that god. Eight of them are in a fine state of preservation. Sir Stamford Raffles, in his history of Java, gives a full account of these edifices, and fine illustrations of them, in a restored condition, are to be found in the plates accompanying the London edition of 1830 of his work.

BRAMBLE, the wild bush that bears raspberries and blackberries, belonging to the natural order *rosacea*, and constituting the genus *rubus*. The essential characters of the genus are: calyx 5-parted, without bractlets; petals 5, deciduous; achenia usually many, collected on a spongy or succulent receptacle, becoming small drupes. Nearly 200 species of this genus have been described. They are perennial herbs, or somewhat shrubby plants, with white (rarely reddish) flowers, and edible fruit; and they are universally diffused over the mountainous and temperate regions of the old and new world. Among the European species are the *R. fruticosus*, or common blackberry, having digitate leaves, with from 3 to 5 leaflets, white paniced flowers, and black or purple

fruit, common throughout Europe in hedges and thickets; the *R. cassinus*, or dewberry, a rougher and more prickly species than the preceding, with trailing stem, found in Europe and in N. E. Asia; the *R. arcticus*, a dwarf species, found in mountainous and northern regions, each stem producing a single highly esteemed fruit; and the *R. idaeus*, or common raspberry, having minute leaves, with from 3 to 7 leaflets, villose, with upright and bristly stems, drooping flowers, and a light-red finely flavored fruit, common from the Himalayas to Ireland. Among the American species are the *R. strigosus*, or wild raspberry, closely resembling the

last, but having longer petals, common on thickets and hills, especially throughout the northern states; the *R. occidentalis*, black raspberry, or thimbleberry, glaucous, with recurved stems, armed with hooked prickles, with umbellate flowers and a purple-black fruit, found in thickets and fields from Canada to the West Indies; the *R. odoratus*, a sweet-scented raspberry, with fragrant foliage, large purple flowers, and a shrubby stem, found on rocky banks northward from the Alleghenies; the *R. villosus*, or high blackberry, shrubby, armed with stout prickles, having 3 or 5 ovate, unequally serrate leaflets, numerous racemed flowers, and a blackish fruit, common in the borders of

Dewberry (*Rubus cassinus*).

thickets, and varying much in size and aspect; the *R. Canadensis*, low blackberry, or dewberry, shrubby, trailing, prickly, common on

rocky or gravelly hills, and having a large and sweet fruit; and the *R. trivialis*, or low bush

Blackberry (*Rubus villosus*).

blackberry, with evergreen, nearly glabrous, ovate-oblong or lanceolate leaves, and large petals, growing chiefly in sandy soil southward.

BRAMHALL, John, an English divine and polemic, born at Pontefract, Yorkshire, about 1598, died in Ireland in June, 1663. He was created bishop of Londonderry in 1634, and archbishop of Armagh in 1661, and was instrumental in restoring the temporalities, and inducing the church of Ireland to embrace the 39 articles. In 1640-'41 he was impeached, together with several of Lord Strafford's coadjutors, by the Irish house of commons. After the battle of Marston Moor he retired for a time to Hamburg. He was an industrious controversial writer, and is chiefly known by his dispute with Hobbes "concerning liberty, necessity, and chance." His works were republished in the "Library of Anglo-Catholic Theology" (5 vols., Oxford, 1842-'5).

BRAN, the husky covering which separates from grain when it is ground and bolted. Rye and wheat bran contain different proportions of constituents, as is shown by the following analyses by Oudemans and Poggiale:

CONSTITUENTS.	RYE BRAN.	WHEAT BRAN.	
	Oudemans.	Oudemans.	Poggiale.
Ash.....	3.85	6.52	5.5
Water.....	14.55	14.07	12.7
Fat.....	1.86	2.46	2.9
Nitrogenous matter.....	14.50	18.46	13.0
Dextrine.....	7.79	5.52	7.9
Starch.....	38.19	26.11	21.7
Cellulose.....	21.35	20.50	34.6
Sugar.....			1.9
Total.....	101.59	98.94	100.2

Payen found that the gluten in the grain increased in quantity from its centre toward the outer covering, thus showing that the removal of the husk must abstract a part of the most nutritious portion. Bread made of unbolted

flour is often used as a laxative article of diet in dyspepsia. In France and Germany it is the common food of the peasantry, and among no people are complaints of indigestion more rare. It has been found by experiment that dogs can live on bran bread, though they cannot on flour bread. But according to Poggiale, when animals are fed on it they rapidly lose flesh; this may be caused by its too irritating properties when fed alone. Mixed with all the flour, it probably yields considerable nutriment. It contains the nitrogenous principle cerealine, analogous to diastase, possessing the property of changing starch into dextrine and grape sugar.—Calico printers remove the non-mordanted colors from maddered goods by boiling them in bran water. Dyers use bran in making the "sour water" for preparing their dyes.

BRANCALEONE, Dandolo, an Italian statesman, died in 1258. He was a Ghibelline senator of Bologna, and in 1253 was invited by the Romans to become their podestà with dictatorial powers. He restored peace and order, and Gibbon says that "no criminals were so powerful as to brave, so obscure as to elude, the justice of the senator." He caused two members of the noble Annibaldi family to be executed, and demolished in the city and its environs 140 towers which served as shelters to the disturbers of the peace. He curbed the power of the pope, the clergy, and the nobles, and put down public robbery with an iron hand. But the people, though benefited by his administration, became exasperated against him; he was deposed, arrested, and probably would have been executed if he had not provided against this by retaining at Bologna as hostages 80 members of the most eminent Roman families. Bologna was in consequence placed under interdiction by Pope Innocent IV. The Roman people at length began to appreciate the great services of Brancalone, and in 1256 he was brought in triumph from prison to the capitol, and continued in power during the remaining two years of his life. His death was regarded as a public calamity; and "his head, enclosed in a costly vase, was deposited on a lofty column of marble." His biography is in the *Historia Major* of Matthew Paris.

BRANCH, a S. county of Michigan, bordering on Indiana; area, 528 sq. m.; pop. in 1870, 26,226. The St. Joseph and Prairie are the principal rivers; there are several small lakes. The Michigan Southern and the air-line division of the Michigan Central railroad pass through the county, and the Fort Wayne, Jackson, and Saginaw railroad touches the S. E. corner. The soil is a rich sandy loam; the surface undulating and occupied by dense forests and oak openings. Iron is found in several places. The chief productions in 1870 were 420,706 bushels of wheat, 454,593 of corn, 185,707 of oats, 322,145 of potatoes, 35,691 tons of hay, 684,689 lbs. of butter, 277,261 of wool, 62,637 of maple sugar, and 223,425 of flax. There were 7,704 horses, 7,313 milch

cows, 8,892 other cattle, 60,877 sheep, and 14,528 swine. Capital, Coldwater.

BRANCHIOPODA (Gr. *βράγχια*, gills, and *πούς*, a foot), an order of the section *entomostraca* of the crustacea, the animals of which are small, mostly inhabit stagnant fresh water, and are provided with feet which are used only for swimming, except that in some instances they contain the organs of respiration. The bodies are protected by a corneous or membranous covering, with a shield in one piece, or divided like a bivalve shell. One species, the *branchipus stagnalis*, is common in New England in stagnant pools. It is about an inch long, and is furnished with numerous fringed legs, which are in constant motion.

BRANCO, Rio, a river of N. Brazil, rises from various sources in the Pacaraima mountains on the confines of Venezuela and British Guiana. After a S. course of about 400 m., in which it receives numerous affluents, it falls into the Rio Negro, in lat. 1° 25' S., lon. 62° 10' W.

BRANDE, William Thomas, an English chemist, born in London, Jan. 11, 1788, died at Tunbridge Wells, Feb. 11, 1866. He received his early education at Westminster, subsequently attended the lectures at St. George's hospital, commenced lecturing on chemistry in 1808, and in the following year was chosen fellow of the royal society. In 1812 he became professor of chemistry and materia medica to the apothecaries' company, and in 1851 was elected master. In 1813 he was appointed professor of chemistry at the royal institution, and was for many years associated with Faraday as editor of the "Quarterly Journal of Science." In 1825 he was appointed superintendent of the department of the royal mint, and some years after fellow and examiner of the London university. Besides his "Manual of Chemistry" (6th ed., 1848), he published "Outlines of Geology" (1839), and a "Dictionary of Science, Literature, and Art" (royal 8vo, 1842; revised ed., 3 vols. 8vo, 1865-'7).

BRANDENBURG. I. A central province of Prussia, consisting chiefly of the ancient mark of Brandenburg, bounded N. by Mecklenburg and Pomerania, E. by the provinces of Prussia and Posen, S. by Silesia and the kingdom of Saxony, and W. by Prussian Saxony, Anhalt, and Hanover; area, 15,402 sq. m.; pop. in 1871, 2,863,461, of whom about 70,000 were Roman Catholics, 40,000 Jews, and the remainder Protestants. It embraces the former territories of Priegnitz and Uckermark in the north, Havelland and Banin in the centre, Neumark in the east, and Mittelmark and Lower Lusatia in the south. It is divided into the districts of Frankfurt and Potsdam, which are subdivided into 81 circles. The chief towns are Berlin, Potsdam, Frankfort-on-the-Oder, Brandenburg, and Spandau. The principal streams are the Elbe, Oder, Havel, and Spree. The surface, which is mainly level, is dotted with numerous lakes, swamps, and morasses, many of which have been drained. The soil

is generally sandy and poor, but near the lakes and streams rich land is found. The principal productions are buckwheat, rye, potatoes, wool, flax, tobacco, and honey. Manufacturing is extensively pursued, and the province is intersected by numerous railroads and canals. Lime and gypsum are found.—Brandenburg was originally inhabited by various German tribes, chiefly of the Suevic race, who were succeeded in its possession by Wends, Wiltzes, Obotrites, and other Slavs. These were subjected to the Frankish sway by Charlemagne, but subsequently recovered their independence, and carried on long feuds with their neighbors the Thuringians and Saxons, until parts of their territory were conquered about 927 by the emperor Henry the Fowler, who founded the Nordmark, or mark of Salzwedel (subsequently known as Altmark, and now forming the northern part of the Prussian province of Saxony). His son Otho I. founded the bishoprics of Brandenburg and Havelberg, and the Germanization of the country now kept pace with its Christianization, the Wends and other Slavs stubbornly contesting the possession of the territories E. of the Elbe. New marks were now successively erected by the emperors in the conquered territories. The subjection of the Slavs was completed by Albert the Bear, count of Ballenstedt, of the house of Ascania, who in 1138 was appointed by the emperor Lothaire margrave of the Nordmark. Albert conquered the Priegnitz territory and the Mittelmark, and assumed the title of margrave of Brandenburg. He founded many towns, and drew German and Flemish settlers into the country. He was also made duke of Saxony, but was unable to maintain this possession against Henry the Lion. Without being himself endowed with the electoral dignity, he may be considered the founder of the electorate of Brandenburg. He died in 1170. His elder grandson, Otho II., ceded considerable territories to the ecclesiastical dominion of Magdeburg, but the younger, Albert II. (1206–1221), again enlarged Brandenburg. The same was done by his sons, John I. and Otho III., who after a united reign of nearly 40 years divided the marks, Stendal and Salzwedel becoming their capitals. John, the founder of the elder line, was the first to assume the dignity of elector. Among his successors was Waldemar (1308–1319), a warlike prince. His line became extinct in 1320, the younger three years earlier. A period of distraction and decay followed, during which Brandenburg came into the possession of the house of Bavaria, was disputed by a pseudo-Waldemar, and finally acquired by the house of Luxemburg, the emperor Charles IV. bestowing it successively on his sons Wenceslas and Sigismund. The last named, on his election as emperor in 1411, appointed Frederick of Hohenzollern, burgrave of Nuremberg and ancestor of the royal line of Prussia, administrator of Brandenburg, in 1415 made him elector, and on April 18, 1417,

the new elector was solemnly inaugurated at Constance. (See HOENZOLLEEN, and PRUSSIA.) II. A town of the above described province, in the district of Potsdam, on both sides of the Havel, 35 m. W. S. W. of Berlin; pop. in 1871, 25,828. It has a cathedral of the 14th century, situated on an island in the river, a castle, gymnasium, council house, several schools and churches, a public library, a theatre, and hospitals. There are several breweries, and manufactories of woollens, linens, hosiery, paper, hats, leather, &c. The trade is considerable. The railroad from Berlin to Magdeburg crosses the town. The name both of the town and the province is derived from Brennibor or Branibor (forest castle), the Slavic name of the old castle conquered by Henry the Fowler.

BRANDIS, Christian August, a German philosopher, born at Hildesheim, Feb. 18, 1790, died in Bonn, July 24, 1867. He studied at Kiel and Göttingen, and lectured at the university of Copenhagen. In 1816 he removed to Berlin, whence he went to Rome as secretary of legation to Niebuhr. He soon returned to Berlin, and was associated with Immanuel Bekker in editing the works of Aristotle. In 1821 he was appointed professor of philosophy at Bonn. From 1837 to 1840 he was cabinet councillor in Greece, and on his return resumed his professorship at Bonn, and published *Mittheilungen über Griechenland* (Leipsic, 1842). His principal works are the *Handbuch der Geschichte der griechisch-römischen Philosophie* (3 vols., Berlin, 1835-'65), and *Geschichte der Entwicklungen der griechischen Philosophie und ihre Nachwirkungen im römischen Reiche* (2 vols., 1862-'4).

BRANDY (Ger. *Branntwein*, burnt wine), a spirit distilled from wine, the fermented juice of the grape, and in the United States from the fermented juice of other fruits, as the cherry, apple, pear, and peach. In the north of Europe the name is also applied to a spirit distilled from grain. The peculiar taste and aroma of wine brandy are due to a volatile oil derived from the husk of the grape. Rectification by repeated distillation clears the liquor of this fragrant substance, as also of its water, and converts it into alcohol. The average proportion of the latter in brandy varies from 48 to 54 per cent. The essential oil, when distilled from the husk alone, is so powerful that a few drops of it are sufficient to taint a large cask of spirit. Besides these ingredients, brandy contains coloring matter, tannin, ænanthic ether, and a little acetic ether. Cider, peach, perry, cherry, and other brandies, only differ from each other and from wine brandy by their peculiar volatile oils, which they contain in very small quantity. Brandies are commonly known as pale or dark. When first distilled, the liquor is without color, and the pale amber tint it acquires is derived from the wood of the cask in which it is kept. This becomes deeper by age, and to imitate it burnt sugar is added to the newly distilled brandy. The best brandies come from France, the most

esteemed being those of Cognac and Armagnac. They are usually rectified by the manufacturers to a specific gravity of only 0.985 to 0.922, and therefore contain more than half their weight of water, and are highly charged with the fragrant essential oil of the grape skin. Sometimes, to save expense of carriage, the liquor is more highly distilled; but this deteriorates it by causing a loss of much of the volatile fragrant oil. As the value of these brandies is greatly increased in consequence of partial failures of the vintage, and the largely increased demand, it has become an object to adulterate them, so that pure French brandy is now hardly to be obtained. Common whiskey is exported from the United States to France in large quantities, and is brought back converted into a factitious brandy. Brandy is also produced from a variety of other ardent spirits. Rum, beet-root spirit, and that of potatoes, are largely used in France for its manufacture, and similar processes are also carried on in this country. From the immense quantities of pure spirits imported into France, and the small quantity exported, except in the shape of brandy and wine, it follows that a great proportion of these are nothing more than grain or beet-distilled liquor, colored, flavored, and named to suit the market to which it is sent. The inferior spirits are carefully rectified by repeated distillations over freshly burnt charcoal and quicklime, to deprive them of their peculiar flavors, which would if left behind betray the imposition; and the essential oils are then added, which have the odor of the ether it is desired to imitate. Dr. Ure gives a recipe for manufacturing factitious brandy, which he says is free from the deleterious drugs too often used to disguise and increase the intoxicating power of British brandies, and which may be reckoned as wholesome as alcohol in any shape can ever be. To pure alcohol diluted to the proof pitch, from half a pound to a pound of argol dissolved in water is added, and with this a little acetic ether, also some French wine vinegar, bruised French plums, and flavor stuff from Cognac, which is the muck or refuse skins and pips of the grape left after the fermentation of the wine. It contains the less volatile ingredients of the grape, as the salts and most of the water—the alcohol having distilled over. It is largely imported into England to redistil with molasses for manufacturing the article known as "British brandy." The mixture is then distilled over a gentle fire in an alembic furnished with an agitator. Nicely burnt sugar (caramel) is added to the spirit which comes over, to give the dark red tint of age, and a few drops of tincture of catechu or oak bark give the astringent taste and property of the tannin contained in the real brandy. The imitations of brandy so far produced are not so perfect but that they may be easily detected.—The brandy sold in France is generally of two strengths, designated as *à preuve de Hollande* and *à*

preuve d'huile, the former varying from 18° to 20° Baumé. The value of the stronger liquors depends upon the quantity of water that may be added to them to give them the strength of *eau de vie à preuve de Hollande*. There are usually twelve grades, designated as five-six, four-five, three-four, two-three, three-five, four-seven, five-nine, six-eleven, three-six, three-seven, three-eight, and three-nine. These terms indicate the relative proportions of spirit and water required to produce the Holland proof. The spirit five-six has a specific gravity of 0.9237 or 22° Baumé. On an average, 1,000 gallons of wine yield on distillation from 100 to 150 gallons of brandy.

BRANDYWINE CREEK, a stream which rises in the N. W. part of Chester co., Penn., flows through the interior in a S. E. direction, and empties into Christiana creek at the city of Wilmington, Del. It furnishes power throughout its course for many valuable mill seats. On its banks the Americans, 13,000 strong, under Washington, were defeated by the British, 18,000 strong, under Howe, Sept. 11, 1777.

BRANECKI, or **Braniczki**, **Franciszek Xawery**, a Polish statesman, died in 1819. He was born of an obscure family, most probably of Tartar origin, and served in the military household of Jan Klemens Braniczki. In 1762 he was an attendant of Poniatowski at his visit to St. Petersburg, and the abettor of his amours with Catharine II. When his master became king, Branecki was rapidly advanced through the influence of Catharine, and in 1771 became grand constable. In 1773 he was foremost in facilitating and sanctioning the first dismemberment of Poland. Afterward he was active in forming the confederacy of Targowitza in 1792, which resulted in the second dismemberment. In 1794 he was proclaimed a traitor to his country. After the third and final division of Poland in 1795, he retired with his wife, a niece of the celebrated Potemkin, to the immense estates given him by Catharine in the Ukraine, where he died. His descendants are among the richest proprietors in Russia. They received the title of counts in 1841.

BRANICKI, **Jan Klemens**, a Polish statesman, born in 1688, died Oct. 9, 1771. In his youth he served in the French army. About 1715 he returned to Poland; where he rose to the highest dignities, and was an opponent of King Augustus II. and the zealous champion of the nobility. After the death of Augustus III. he officiated as grand constable and first senator of the kingdom, and stood at the head of the republican party. He was offered the crown by a great majority of the nobles; but, backed by Russia, Poniatowski was elected, while Braniczki was outlawed, and escaped to Hungary. The new king, however, who was his brother-in-law, soon recalled him, and restored him to his dignities. He was called by the nation the last patriot, and at his funeral was performed for the last time the mediæval ceremony of the ancient chivalry, that of breaking

the coat of arms, and entombing it with the body of the last member of a noble line.

BRANT, a S. W. county of Ontario, Canada, drained by Grand river and traversed by the Great Western and the Buffalo and Lake Huron railways; area, 416 sq. m.; pop. in 1871, 33,269. The surface is somewhat diversified, but most of it is level. The soil is exceedingly fertile. Capital, Brantford.

BRANT, **Joseph** (**THAYENDANEGA**), a Mohawk chief, born in Ohio about 1742, died on his estate at the head of Lake Ontario, Canada, Nov. 24, 1807. Having taken a part in the campaign of Lake George in 1755, and in various subsequent conflicts, he officiated after Sir William Johnson's death as secretary of Col. Guy Johnson, superintendent general of the Indians; and when the American revolution began he was instrumental in exciting the Indians against the colonies. He took part in the massacre of Cherry Valley, and in other sanguinary affairs. He had been sent about 1760 to Dr. Wheelock's Indian school in Connecticut, and in 1775-'6 he visited England. He was received with great distinction on a second visit to that country in 1786, and was afterward attached to the military service of Sir Guy Carleton in Canada. He opposed the confederation of the Indians which led to the expedition of Gen. Wayne, and exerted himself to preserve peace between the Indians and the United States. He was, however, zealously devoted to the welfare of his own people, and conspicuous for his efforts to prevent the introduction of ardent spirits among them. During his stay in England he collected funds for a church, and published the "Book of Common Prayer" and the Gospel of Mark in Mohawk and English. One of his sons in 1811 and 1812 led a body of Canadians and Indians employed by Great Britain against the United States. The "Life of Joseph Brant," by W. L. Stone (1830), has passed through many editions; the latest, New York, 1865.

BRANTFORD, a town of Canada, province of Ontario, capital of the county of Brant, W. of Lake Ontario, 60 m. S. W. of Toronto, and 75 m. N. W. of Buffalo; pop. in 1871, 8,107. It occupies a commanding position on the banks of the Grand river. The county buildings were erected at a cost of \$40,000. It has an excellent system of water works, constructed at a moderate cost, and is well lighted with gas. Several branches of manufacture employ a large number of persons. Among them are engine works, founderies, and manufactories of agricultural implements. There are ten churches, and a widows' and an orphans' home. Situated on the Goderich and Buffalo railway, its facilities of access to all points east and west are excellent. Until 1830 the town plot was a reserve of the Six Nations.

BRANT GOOSE. See Goose.

BRANTÔME, **Pierre Bourdelles**, seigneur de l'abbaye de, a French historian, born between 1527 and 1540, died July 5, 1614. Familiar

with military life at the headquarters of François de Lorraine, second duke of Guise, and on various battle fields where he showed prowess, he had many opportunities of becoming acquainted with the events of the 16th century; and his field of observation was greatly enlarged by extensive travels and by his relations with the court and with literary and general society. He was gentleman in ordinary to Charles IX., shortly after whose death (1574) he retired from the court, after having been for a time chamberlain of Henry III., by whom he was less appreciated than by Charles. He was particularly disappointed at the time of the death of his elder brother André (1582), when Henry made the latter's son-in-law seneschal of Périgord, instead of investing Brantôme with this office, which up to that period had been hereditary in the Bourdeilles family. In his exasperation he proposed to take service against France with Philip II. of Spain; but he speedily returned home on hearing of the outbreak of civil war, and henceforth lived with his brother's widow and children, preparing works which were published after his death. His writings are pervaded by a cynical and frivolous spirit, but his style is lucid and attractive, and his acute observations throw much light upon the leading persons and events of his day. The first editions of the *Mémoires de Pierre Bourdeilles, seigneur de Brantôme*, appeared in Leyden (10 vols. 12mo, 1666-'7 and 1699), afterward several times reprinted elsewhere (German translation by Alvensleben, 2 vols., Grimma, 1851). Besides his *Mémoires*, he wrote *Vies des hommes illustres et des grands capitaines français et étrangers*; the entertaining *Dames illustres et dames galantes*; and *Anecdotes touchant les duels*. Collective editions were published at the Hague (15 vols. 12mo, 1740), and Paris (8 vols. 8vo, 1787). A new edition was included in Petitot's *Mémoires relatives à l'histoire de France*, with annotations by L. J. N. de Monmerqué (1823), after original MSS. in the national library revised by Brantôme himself. Among the biographers of Brantôme, besides Monmerqué, are Mérimée and Lacour (Paris, 1858 *et seq.*).—Brantôme had three brothers and two sisters, the most eminent of whom, especially as a soldier and diplomatist, was the viscount André de Bourdeilles, privy councillor of the king and seneschal and governor of Périgord from 1572 till his death in 1582. His life, military writings, and correspondence with Charles IX., Catharine de' Medici, and Henry III., fill the 8th volume of Monmerqué's edition of Brantôme's works.

BRAOUËZEC, L. E., a French explorer, born at Morlaix, Oct. 29, 1828, died April 3, 1870. Stationed on the W. coast of Africa as a naval commander, he examined in 1858-'9 the Gaboon, Senegal, and other rivers, and wrote *Notes sur les peuplades riveraines du Gabon, de ses affluents et du fleuve Ogo-uevai*, and memoirs on various African explorations. He died after

his return to France from the effects of the African climate.

BRASCASSAT, Jacques Raymond, a French painter, born in Bordeaux, Aug. 30, 1805. In 1825 he gained the second prize at the school of fine arts for a historical landscape illustrating the hunt of Meleager, and subsequently travelled and studied five years in Italy at the expense of the duchess de Berri. For many years he has been a regular contributor to the annual expositions in Paris, and is noted for his animal pieces. He is a member of the academy of fine arts, and has several times received a first medal. His chief works comprise "Bulls Fighting," in the museum of Nantes, "Cow attacked by Wolves and defended by a Bull," "Bull Butting against a Tree," and pictures of dogs, sheep, cattle, and wolves, which usually have a background of wooded landscape.

BRASIDAS, a Spartan leader in the Peloponnesian war, died in 422 B. C. He is first mentioned in history in connection with the successor of Methone (431 B. C.), with a handful of men and by his personal bravery, from a powerful attack by the Athenians. This exploit gained him the first public honors conferred by the Spartans during the war. In 429 he was sent as one of three counsellors to Cnemus, after his defeat by Phormio. With Cnemus he made an unsuccessful plan to surprise the Piræus; the reason of the failure is not satisfactorily explained by the historians. In 427 he served with Alcidas, the Spartan admiral, and in 425 he led the attempt to drive Demosthenes, the Athenian leader, from Pylos. In 424, while he was preparing for an expedition to Chalcidice, Megara was suddenly attacked, and he promptly effected its relief. Shortly afterward, being sent against the Athenians in Thrace, he conducted a rapid and skilful march across the hostile country of Thessaly, assisted Perdiccas the Macedonian against a neighboring enemy, Arrhibæus, and then marched upon Acanthus, which, as well as Stagira and Argilus, he persuaded to revolt from Athens. Amphipolis, surprised by a quick march, surrendered to him, and before the end of a year Brasidas had either by arms or persuasion gained the accession of nearly every town in that district. At Torone and Leucythus he encountered the chief resistance. In 423, after suppressing revolts in Scione and Mende, he undertook another expedition with Perdiccas against Arrhibæus; it was unsuccessful, but Brasidas made a masterly retreat. While this was going on the Athenians recaptured Mende and held it. In 422 Cleon brought a large Athenian army against Amphipolis, where the Spartans had their chief garrison; the cities around surrendered, leaving Brasidas exposed with his small force to greatly superior numbers. Seeing that the only hope of the city lay in a sally against the besiegers, the Spartan leader marched his men out of the place, and engaged the enemy with such success as to secure a complete victory. Cleon

was killed, but Brasidas himself was mortally wounded, and died soon after. He was buried with extraordinary honors by the Spartans at Amphipolis, and yearly sacrifices were long offered to him there.

BRASS. Of all the alloys of one metal with another, none are more useful than those of copper with zinc, forming the different varieties of brass. This alloy appears to have been in use at a very early period, if the Latin word *es* is correctly translated brass instead of copper; for Lucretius observes, *Et prior erat aris quam ferri cognitus usus*—"The use of brass was known before that of iron." Pliny speaks of its use soon after Rome was founded, and states that Numa, the successor of Romulus, formed the workers of it into a kind of community. It is also certain that before zinc was ever obtained as a distinct metal, its alloy with copper was in use, the zinc ores being reduced in process of making the alloy by the charcoal mixed with them; when thus formed, the metallic zinc is absorbed in the copper placed in the crucible, without once appearing in its own form. Brass continued to be manufactured in this manner till the year 1781, when James Emerson obtained a patent for making it by direct fusion of its metallic elements. His method, which is still employed, is to melt the metallic zinc and introduce the copper in thin slips. When enough is added to render the alloy difficult of fusion, the heat is increased and the additional copper required is introduced in a melted state. Another process is to melt the copper first and introduce the zinc with iron tongs; but at the present time brass is usually made by placing the copper and zinc in alternate layers in fire-clay or graphite crucibles, and smelting them under a thick layer of charcoal. When the fusion is complete the alloy is cast into granite moulds luted with clay. Owing to the uncertain quantity of zinc which escapes in consequence of the high melting point of copper, which is above 2,200° F. (Daniel, 2,548°), while that of zinc is only about 770°, it is difficult to exactly preserve the proportions of the two metals. Old brass is often used, which also complicates the estimation of the relative quantities of the constituents. From these causes the exact composition is never known except from analysis. The best proportions to make fine brass are two equivalents of copper, $31.7 \times 2 = 63.4$, and one equivalent of zinc, 32.5; or in 100 parts, 66.11 of copper to 33.89 of zinc. The usual practice is to mix two parts of copper, by weight, with one of zinc. The quality of brass, in regard to its ductility, malleability, and tenacity, varies much according to the proportions of its ingredients. In certain proportions it is more ductile at ordinary temperatures than pure copper, but it is generally brittle at a red heat. The most ductile of all the alloys of copper and zinc are those containing 84.5 per cent. of copper and 15.5 of zinc, called tombac, and brass which contains 71.5 per cent. of copper

and 28.5 of zinc; but in this latter proportion it is not malleable while hot, and articles made of it must be cast. An alloy prepared of 60 parts of copper and 40 of zinc has a fine close-grained fracture and greater density than common brass, and when hot can be rolled into thin sheets. This is known as Muntz's metal, a patent having been obtained for it by Mr. G. B. Muntz of Birmingham in 1832. It has to a great extent superseded copper for sheathing ships, and possesses the advantages of keeping the bottoms cleaner and of being less expensive. The addition of one or two per cent. of lead to brass improves its quality for being worked with tools, but impairs its toughness by diminishing its adhesiveness. Bath metal, Prince's metal, tombac, pinchbeck, Mannheim gold, and other alloys resembling inferior jeweller's gold, contain 80 per cent. or more of copper; and on account of the expensiveness of tin, have been much used as substitutes for bronze. Oreide is the name given by Meurier and Valient of Paris to an alloy of golden brilliancy. It is prepared by fusing 100 parts of copper, by weight, and adding 6 parts of magnesia, 3.6 parts of sal ammoniac, 1.8 part of quicklime, and 9 parts of crude tartar gradually, and stirring for about half an hour. Seventeen parts of zinc are then added, and after stirring, the crucible is covered and kept hot for about 35 minutes. It is then uncovered, and the alloy carefully skimmed and cast into a metal or moist sand mould. It has a fine grain, is malleable, takes a brilliant polish, and may have its complexion restored by acidulated water. Corinthian brass was an alloy of gold, silver, and copper. In the following table of the composition of various alloys of copper and zinc used in the arts, taken from Watts's "Dictionary of Chemistry," it will be observed that some specimens contain small portions of tin and lead, in some cases enough of the former to approach the character of bronze:

ALLOYS	Copper.	Zinc.	Tin.	Lead.
English brass.....	70.20	29.26	0.17	0.28
Brass from Augsburg.....	71.89	27.63	0.85	..

If copper sheets are exposed at a red heat to the vapors of zinc, they are completely penetrated by them and converted to brass. Lyons gold lace is made by thus exposing copper rods to the vapor of zinc until the surface is converted to brass, and then drawing them out into wire. If a copper coin is placed in a crucible above a

mixture of zinc oxide and charcoal, and heated, it will become brass without obliteration of the device.—Brass is much used for the bearings of machinery, for making the reeds of wind musical instruments, for those parts of machinery where iron would be objectionable or where ornamentation is desired, for various kinds of tubing, for tacks, bolts, and screws, and for optical and other instruments of like construction.—Brass solder is usually composed of two parts of brass to one of zinc, but the proportions may be made according to the desired degree of fusibility, which property is almost in exact proportion to that of the zinc used. (See BRAZING.)

BRASSEUR DE BOURBOURG, Charles Étienne, abbé, a French traveller and archæologist, born at Bourbourg, near Dunkirk, Sept. 8, 1814. He studied theology at the university of Ghent, was ordained at Rome in 1845, became professor of ecclesiastical history at the Roman Catholic seminary of Quebec, and in 1846 was appointed vicar general at Boston. With the exception of intervals employed in visiting Rome and Paris, he was from 1848 to 1863 almost uninterruptedly engaged in exploring the United States, Mexico, and Central America, acting sometimes as chaplain of the French embassy in Mexico and as teacher of Indians in Guatemala. In 1864 he went to Mexico as archæologist of the French scientific expedition. His principal works are: *Histoire du Canada, de son église*, &c. (2 vols., 1852); *Histoire des nations civilisées du Mexique et de l'Amérique Centrale avant Christophe Colomb* (4 vols., 1857-'9); and *Collection de documents dans les langues indigènes pour servir à l'étude de l'histoire et de la philologie de l'Amérique ancienne* (3 vols., 1861-'4). The third volume, relating to Yucatan, was republished in 1864 under the title of *S'il existe des sources de l'histoire primitive du Mexique dans les monuments égyptiens, et de l'histoire primitive de l'ancien monde dans les monuments américains*. His illustrated work, *Monuments anciens du Mexique*, &c., was published in 1864-'6 under the auspices of the French government. A second edition of his youthful novel, *La dernière vestale*, was published in 1858, and of *Le khalife du Bagdad* in 1859. The *Bulletin* of the French geographical society (March, 1864) contains his letter from Spain (November, 1863) to M. de Quatrefages announcing his discovery in the archives of Madrid, after many years of research, of the alphabets of the inscriptions on the Central American monuments. These alphabets are phonetic, and by aid of the *Codex Mexicanus* and the library of Dresden he claims to have deciphered several words. He has recently published a catalogue of a part of his collection of early grammars and vocabularies of Aztec languages.

BRASSEY, Thomas, an English railway contractor, born at Boughton, Cheshire, in 1805, died Dec. 8, 1870. His first railway enterprise was the construction of a Welsh road.

In 1836 he made a contract for a small portion of the line between Birmingham and Liverpool, a part of the London and Northwestern railway, and was subsequently widely engaged in similar enterprises both in England and abroad. In several of these he was associated with Sir Morton Peto and others. His sons, T. Brassey and J. H. A. Brassey, represent Hastings and Sandwich in the house of commons (1873). He is said to have left to his family about £6,000,000, besides extensive landed property. His biography by Arthur Helps was published in 1872.

BRATTLE, Thomas, an American merchant, born in Boston, Sept. 5, 1657, died there, May 18, 1718. He graduated at Harvard college in 1676, and was afterward treasurer of that institution. There is preserved in the "Historical Collections" a letter by him, containing an excellent account of the witchcraft delusion in 1692. Several of his communications on astronomical subjects were published in the "Philosophical Transactions."

BRATTLEBORO, a post town of Windham co., Vt., on the W. bank of the Connecticut river, about 100 m. S. of Montpelier and 96 m. W. of Boston; pop. in 1870, 4,933. The first settlement of the state was made here in 1724, when a military post called Fort Dummer was erected on a spot now known as "Dummer's meadows." The town contains an East and West village. The West village, on Whetstone creek, is devoted principally to agriculture. The East village is situated on the Connecticut river at the mouth of Whetstone creek, and on the Connecticut River railroad. A covered bridge across the Connecticut river connects it with Hinsdale, in New Hampshire. It is one of the wealthiest villages in the state. In 1836 an asylum for the insane, endowed with \$10,000 by Mrs. Anna Marsh, and still further enriched with appropriations by the state, was opened at a short distance N. W. of the village. The Brattleboro typographic company, established in 1836, with a capital of \$150,000, had a paper mill and an extensive printing house, but ceased operations about 1842. There are three hotels, a female seminary, several churches, and two water-cure establishments. Two weekly papers and two monthly periodicals are published in the town.

BRAUN, August Emil, a German archæologist, born at Gotha, April 19, 1809, died in Rome, Sept. 12, 1856. For more than 23 years he was secretary of the archæological institute at Rome. His last productions were: *Die Griechische Götterlehre* (Gotha, 1850-'54); *Die Vorschule der Kunst-Mythologie* (Gotha, 1854, with 100 plates; English translation by Grant, Gotha, 1856); and his guide book entitled *Die Ruinen und Museen Roms* (Brunswick, 1854; translated into English in 1855).

BRAUN, Johann Wilhelm Joseph, a German theologian, born near Düren, Prussia, April 27, 1801, died in Bonn, Sept. 30, 1863. He was ordained at Vienna in 1825, completed his

studies at Rome, and became professor in the university of Bonn in 1827. In conjunction with Hermes and Droste-Hülshoff, he founded *Die Zeitschrift für Philosophie und katholische Theologie*. In 1835 Hermes's lectures were suspended by order of the Vatican, and in 1837 Braun proceeded to Rome; but his efforts to change the decision of the pope were not successful, and in 1843 he was himself compelled to relinquish his professorship. In 1848 he became a member of the Frankfort parliament, and in 1850 of the first chamber of the Prussian diet. He was the author of a number of works, theological, literary, and political.

BRAUNSBURG, a town of Prussia, in the district and 34 m. S. W. of Königsberg, on the Passarge, near the Frische Haff; pop. in 1871, 10,471. It was formerly the seat of the bishops of Ermeland. It has an ancient castle, a Roman Catholic lyceum, theological and philosophical faculty, a Catholic gymnasium, and several churches.

BRAUWER, or Brouwer, Adrian, a Dutch painter, born at Haarlem, or at Oudenarde in East Flanders, in 1608, died in Antwerp in 1640. He first made designs of flowers and birds, which were stitched upon caps and bonnets sold to the peasants by his mother. Francis Hals, a painter of Haarlem, happening to see some of these, invited the young artist to receive instruction at his house, where he kept him hard at work in a garret, and appropriated to himself the proceeds of his pictures. Here Brauwer remained for many months, ignorant of the estimation in which his talent was held abroad, until by the assistance of his fellow pupil, Adrian Ostade, he was enabled to escape to Amsterdam, where he led a dissipated life and painted only when impelled by necessity. During the wars with Spain he started on a journey to Antwerp, but, being unprovided with a passport, he was imprisoned as a spy. The prince of AreMBERG, a fellow prisoner, recognizing his talent, induced him to paint something. The subject was a group of soldiers playing at cards, which the artist sketched from his prison window; and the picture being shown to Rubens, he at once pronounced it a work of Brauwer, whose release he immediately procured, and whom he received as an inmate into his house. Brauwer's longing for his old life, however, soon induced him to leave his protector, and after a brief career of dissipation he died in a public hospital.

BRAVO, Nicolas, a Mexican soldier and statesman, born at Chilpancingo about 1790, died there, April 22, 1854. He took part in the first revolution in 1810, and served in all the actions till 1814. Having joined Minas's party in 1817, he was imprisoned in Mexico till 1820. He was a zealous supporter of Iturbide, and became a member of the regency which exercised the supreme power for 40 days in 1822; but he contributed to the deposition of the emperor in 1823, and was a member of the provisional government till 1824. In December, 1827, he

headed a revolt against President Bustamante, he being at the time vice president himself, which office he held till April, 1829. In 1830 he commanded against the insurgents under Guerrero, who was captured and executed by Bravo's order, Feb. 17, 1831. In 1839 he became president of the council, and in 1842-'3 held the supreme power for a few months as substitute of Santa Anna, absent with the army; and he was again temporary president from July 29 to Aug. 4, 1846, when he was deposed by a revolution. During the war with the United States he participated in the battle of Cerro Gordo; and toward the end of 1853, being accused by Santa Anna's ministry of having secretly joined the insurrection headed by Juan Alvarez, he denied the accusation and retired from public life. His death was sudden, and attended by suspicious circumstances.

BRAVO MURILLO, Juan, a Spanish statesman, born at Frejenal de la Sierra in 1803. He studied theology, and afterward law, and began to practise in 1825. He was fiscal at Cáceres from 1833 to 1835. In 1836 he founded at Madrid the *Boletín de Jurisprudencia*, the first law journal in Spain, and edited for the moderados *El Porvenir*, and in 1837 *El Piloto*. He became an influential member of the cortes in 1837, and upon the revolution of 1841 was proscribed and fled to France. He returned in 1843, but confined himself to his profession. In 1847 he entered the ministry of Narvaez, and when the latter resigned in 1850 took his place as prime minister, holding it as an extreme absolutist till 1852. He again had to fly after the revolution of 1854, but was recalled by the counter revolution of 1856. He has since held important diplomatic positions.

BRAXTON, a central county of West Virginia; area, 646 sq. m.; pop. in 1870, 6,480, of whom 87 were colored. The surface is hilly, and covered with large forests. The soil is well watered, and generally fertile. The Elk, Little Kanawha, and Holly are the principal rivers. Coal is found in several places, and in the northern part are salt springs. The chief productions in 1870 were 20,019 bushels of wheat, 130,690 of corn, 29,908 of oats, and 1,951 tons of hay. There were 1,558 horses, 2,049 milch cows, 2,105 other cattle, 9,923 sheep, and 6,513 swine. Capital, Sutton.

BRAXTON, Carter, a signer of the Declaration of Independence, born at Newington, King and Queen co., Va., Sept. 10, 1736, died Oct. 10, 1797. He inherited several plantations, and in early life resided some years in England. In 1765 he took an active part in the session of the house of burgesses of Virginia, in which the resolutions of Patrick Henry were adopted, and in the subsequent assemblies which were dissolved by the governor. On Dec. 15, 1775, he was elected delegate to the continental congress, as successor of Peyton Randolph. He did not remain long in congress, but served in the legislature of Virginia till 1786, when he became one of the executive council.

BRAY, a small parish of Berkshire, England, 23 m. W. of London. A clergyman who held the vicarage of Bray in the 16th century was a Roman Catholic in the reign of Henry VIII., became a Protestant with that monarch, and remained so during the reign of Edward VI., became a Catholic again in the reign of Mary, and turned Protestant again when Elizabeth ascended the throne of England. On being reproached with his frequent changes of principle, he made answer very wittily: "Not so, neither; for if I changed my religion, I am sure I kept true to my principle, which is to live and die the vicar of Bray!"

BRAY, *Anna Eliza* (KEMPE), an English authoress, born in Surrey about 1800. She married in 1818 Mr. Charles Stothard, an artist and antiquary, whom she accompanied in artistic excursions, and who was accidentally killed in 1821; and about 1825 she became the wife of the Rev. Edward Atkyns Bray, vicar of Tavistock. Mrs. Bray's works (of which a uniform edition in 10 vols. appeared in 1844) consist chiefly of books of travel and historical romances, many of which have been translated into German. One of her most valuable productions is on the "Borders of the Tamar and Tavy," in a series of letters addressed to Southey. Mrs. Bray has written a memoir of her first husband, and in 1851 published that of his father, the eminent artist Thomas Stothard. She has also published a life of Handel (1857), and one of her second husband, with his "Poetical Remains" (1859). Her latest productions are: "The Good St. Louis and his Times" and "The Revolt of the Protestants of the Cévennes" (1870); "Hartland Forest, a Legend of North Devon" (1871); "Joan of Arc, and the Times of Charles VII., King of France."

BRAY, *Thomas*, an English clergyman and philanthropist, born at Morton, Shropshire, in 1656, died in London, Feb. 15, 1780. Being selected by Bishop Compton to build up the infant Anglican church in Maryland, with the title of ecclesiastical commissary, he founded in 1698 the society for propagating the gospel in foreign parts, and sailed for Maryland Dec. 16, 1699, arriving March 12, 1700. He was received with great cordiality, and the "act of religion" was adopted by the legislature as he desired. He returned to England in 1701. Under the patronage of the princess, afterward Queen Anne, he established a number of parochial libraries in America, and he set on foot through England and Wales lending libraries in every deanery, whence the neighboring clergy might borrow books, and where they might meet for mutual consultation. He also engaged in the reformation of prison abuses, the establishment of parish workhouses, and other benevolent undertakings.

BRAZIL (*Imperio do Brazil*), a country of South America, and the only empire in the new world, extending from lat. 4° 30' N. to 33° S., and from lon. 85° to 73° W. It is bounded N. by the United States of Colombia,

Venezuela, British, Dutch, and French Guiana, and the Atlantic ocean; E. by the Atlantic; S. by Uruguay, the Argentine Republic, and Paraguay; and W. by Bolivia, Peru, Ecuador, and the United States of Colombia. It thus borders upon all the South American republics except Chili. It occupies more than two fifths of the South American continent, and has, after Russia, the most extensive contiguous territory of any government on the globe. The line of demarcation at the extreme N. W. has not yet been definitively drawn; but, including the territory annexed to the empire by a recent treaty with Bolivia, it covers an area of about 3,200,000 sq. m. Its greatest breadth is 2,470 m., and its greatest length 2,600. Paraguay in 1872 ceded to Brazil, as a war indemnity, a long disputed territory comprised between the Paraguay and Paraná, N. of the Apa and Igatim. This territory has an area of about 16,000 sq. m. The empire is divided into 20 provinces and one neutral municipality (*município neutro*), which, with their areas, estimated population in 1871, and capitals, are as follows:

PROVINCES.	Area.	Population.	Capitals.
Amazonas.....	696,700	70,000	Manáos.
Grão Pará.....	400,000	320,000	Belem.
Maranhão.....	168,000	385,000	São Luiz.
Piauhý.....	94,500	232,000	Terrezeira.
Ceará.....	42,634	550,000	Portaleza.
Rio Grande do Norte..	18,000	280,000	Natal.
Parahyba.....	81,500	280,000	Parahyba.
Pernambuco.....	57,588	1,250,000	Recife.
Alagoás.....	21,204	800,000	Maceió.
Sergipe.....	12,240	275,000	Aracajú.
Bahia.....	233,524	1,400,000	São Salvador.
Espírito Santo.....	14,049	65,000	Victoria.
Rio de Janeiro.....	26,600	920,000	Niterohy.
São Paulo.....	93,547	885,000	São Paulo.
Paraná.....	72,000	90,000	Coritiba.
Santa Catharina.....	28,220	140,000	Desterro.
São Pedro.....	78,836	420,000	Porto Alegre.
Minas Geraes.....	280,000	1,450,000	Ouro Preto.
Goyaz.....	284,000	151,000	Goyaz.
Matto Grosso.....	551,575	100,000	Cuiabá.
Município Neutro.....	288	450,000	Rio de Janeiro.
Total.....	3,200,000	9,913,000	

The population of Brazil has been variously estimated at different periods, since no facilities exist for computing it with absolute accuracy, and no regular census has been taken. Some authorities set it down as high as 12,000,000, while others admit no more than 7,000,000. The foregoing table, however, is believed to present the closest approximation to truth at the present time (1873). The population of the leading cities is as follows: Bahia, 150,000; Belem or Pará, 25,000 to 40,000; Portaleza, 16,000; São Luiz de Maranhão, 30,000; Parahyba, 13,000; Recife or Pernambuco, 70,000; Porto Alegre, 22,000; Rio de Janeiro, 450,000; São Paulo, 20,000. Brazil is inhabited by an agglomeration of many races. In the northern provinces the Indian element prevails, while in Pernambuco, Bahia, Rio de Janeiro, and Minas, the negroes are numerous. In the seaports the chief part of the population is of European descent. The whites number probably one third of the entire population,

the remaining two thirds being made up of *mamelucos* or mestizos, mulattos, *cafuzos* (from Indian and negro), civilized and savage Indians, and Africans, which last form the most numerous unmixed race in the empire. The Brazilian character, with an admixture of mildness and generosity, has a disposition toward vindictiveness; and homicides from that motive are not uncommon, especially in the interior. The more educated classes, though somewhat ceremonious and proud, have remarkable suavity of manner; and as a nation the people are hospitable, gay, courteous, and communicative, quick at learning, and deeply inspired with the love of theoretical liberty. The aborigines of Brazil were a warlike, ferocious people, of the most revengeful character. Many of them were cannibals; some of them ate their enemies in grand ceremonial; others made war for the purpose of obtaining human food; and still others devoured their relatives and friends as a mark of honor and consideration. The Catauxis and other tribes on the river Purús kill and eat members of other tribes at the present day, and even preserve the flesh thus obtained by smoking and drying it. The number of aboriginal tribes found in Brazil at the time of its discovery was probably not far short of 100. They dwelt mostly in a narrow belt along the coast from N. to S., extending thence back to the Paraguay, and across the region drained by the head waters of the Plata and Amazon. Nearly all these people spoke the same language, which was however divided into numerous dialects and sub-dialects. They were called on the coast Tupí, or by some name having that word for its root; while in the interior they commonly received the name of Guaraní, to which great family they all seem to have belonged, the differences in the tribes resulting from the different situations in which they were placed, and from other accidental circumstances. They were not settled, neither were they wildly nomadic, each tribe having certain limits, where it remained until driven out by a superior force. The plantain, banana, cashew, yam, and above all the mandioca and more than 200 species of palm, furnished them food, drink, and raiment. With few exceptions the Indians of Brazil are of a bright yellowish copper color; they are robust and well made; their hair black, lank, and coarse, and the beard thin; the nose small, the lips not very thick, the face round, eyes small, and skin soft and shining. Nearly all the tribes paint their skin according to fantastical designs. Though usually grave and serious, they do not present the stolid apathy of the northern Indians; they are fond of feasts and pastimes, and are prone to excess in the use of stimulating liquors. Few of them have any definite idea of a Supreme Being, but all believe in the existence of malignant demons. Some tribes practise polygamy. The Botocudos, the most celebrated of all the tribes (see Botocudos), speak a language en-

tirely distinct from the Tupí and from that of the other coast tribes; but all the Brazilian Indians may be communicated with through the *lingoa geral*, the basis of which is the Tupí-guarani, and which was formed by the priests, traders, and slave hunters. The majority of the Indian tribes have altogether disappeared; and some of those still existing have been driven far back into the interior, where they remain in their primitive savagism. The anthropophagous tribes are chiefly confined to the banks of the Doce, Purús, and other tributaries of the Amazon. Many have, however, through the influence of the missionaries, embraced Christianity and become partially civilized, and are for the most part engaged in agriculture. The Indians being found unprofitable as slaves, recourse was had to the importation of negroes from Africa, who in earlier times were treated with unparalleled cruelty; but after the effectual suppression of the slave trade in 1850, the price of slaves became so enhanced that slave owners were impelled by self-interest to relax the severity of their treatment. The facilities for emancipation were nevertheless great; and a man's color does not in Brazil debar him from any civil or political privilege. Persons born in Brazil of African parents are called creoles. A law for the gradual abolition of slavery, passed Sept. 28, 1871, enacts that children henceforth born of slave mothers shall be of free condition, though bound to serve the owners of their mothers for a term of 21 years, as apprentices. Refusal to work for their hereditary taskmasters will be followed by severe penalties; but the apprentices, if cruelly treated, can appeal to a criminal court, which may declare them free. The same act emancipates the slaves that were the property of the government; but they are required to hire themselves out, in default of which, being under the inspection of the government for five years, they will, if found living in vagrancy, be compelled to labor in the public establishments. Large numbers of private individuals have followed the example of the crown and set their slaves at liberty; and others at their death have left them free, with portions of land for their maintenance. About 30,000 slaves were manumitted in this manner between the passing of the emancipation act and the month of December, 1872. Dom Pedro II. attempted to turn the tide of German emigration to Brazil, and a colony was formed on the Rio Grande do Sul; and after the abolition of the slave trade (1850), an act was passed offering liberal inducements to colonists, particularly as to the easy purchase of lands. Planters too entered into the colonization scheme, and by their abuses and bad faith threw discredit upon the attempts of the crown and paralyzed its efforts to people the interior. To prevent these abuses, private associations were formed in Rio de Janeiro and other cities for the purpose of redressing the wrongs of immigrants, providing them with all necessary assistance

and information on their arrival, and protecting their interests as colonists. Immigration from Europe, and chiefly from Germany and Switzerland, has of late years been still further encouraged by the imperial government, which pays a part of each immigrant's passage money. According to official reports, there were in the empire 50 colonies in 1869, with about 40,000 settlers. Many of these colonies, which are for the most part in the provinces south of Rio de Janeiro, have, in consequence of their flourishing condition, become independent of state direction. In 1871, 1,168 persons sailed from Hamburg for Brazil, over 1,000 of whom were Germans. From Jan. 1 to April, 1872, 1,105 had left the same port for the same destination.—Brazil, in shape somewhat resembling a heart, has a coast line of nearly 4,000 miles, extremely varied in its aspect and formation. From the mouth of the Oyapok to that of the Amazon, where it has an immense indentation, it is almost uniformly sandy and rather low; and from that point to the embouchure of the Parnahyba it is low, marshy, and interspersed with widely separated hills of inconsiderable elevation, and presents numerous indentations, the largest of which is that forming São Marcos bay. For about 800 m. S. of the Parnahyba the shores are at first somewhat higher, but afterward gradually sink until Cape S. Agostinhos is reached, where they are very low. Thence, save a long stretch of picturesque red cliffs, alternating with steep verdant slopes and occasional patches of sands or swampy ground, reaching from Porto Seguro to the Piruhype in the southern portion of Bahia, they are very even, and vary but little in elevation as far S. as the bay of Espirito Santo. From this point to Cape Santa Marta the coast is broken by rocks, which attain their greatest height between Cape Frio and Santos in São Paulo. In the W. portion of the province of Rio de Janeiro it is often high, bold, very irregular in outline, and bordered by numerous rocky islands. The remainder of the coast, from Cape Santa Marta southward, is low, sandy, and intersected by numerous lakes, some of which communicate with the ocean through extensive openings. About midway between Bahia and Rio de Janeiro, and nearly 40 m. to seaward, lie the Abrolhos, four rocky islets, the principal one of which, Santa Barbara, rises to a height of 108 ft., is about three quarters of a mile in length, and is composed of beds of sandstone, shales, and trap. The beaches of these islets consist largely, and in some parts entirely, of coral and shell sand. From the Abrolhos northward to the shore of Maranhão, at very irregular and often very long intervals, are scattered true coral reefs, lying in patches at a short distance from the coast, from which they are separated by navigable channels.—Much of the Brazilian territory, probably one half, is covered by highlands and mountains; but all of these are of insignificant proportions and elevation when

compared to the giant ranges of the Andes. Indeed, many rising grounds mapped and described as *serras* have nothing of a mountainous character. The Amazon and Paraguay watershed in the province of Matto Grosso, forming the W. limit of the Brazilian highlands, is simply a low swelling plateau on which the Tapajos, Xingó, Paraguay, and other rivers have their sources; and these are so near to each other, and the watershed is so low, that canoes ascend the Tapajos from Santarem near its confluence with the Amazon, cross over, and descend the Paraguay to Villa Maria. These great river sources might easily be connected by means of a canal. All the great Brazilian ranges N. of the parallel of Diamantina and having a N. and S. direction, though commonly described as mountain chains, are, with the exception of the Serra do Grão Mogor, ranges of *chapadas* or narrow plateaus resulting from denudation. There are in the east two great parallel chains. One of these, the Serra do Mar, runs nearly in a line with the coast, lowering considerably toward the Rio Doce, and losing itself almost entirely in Bahia, about lat. 18° S. The other, situated W. of the shore chain, is the Serra de Villarica or do Espinhaço. It extends from about lat. 25° to 16° S., where it loses itself some 240 m. from the coast; but between 22° and 28° it draws so near the Serra do Mar as to be confounded with it. The Serra do Mar, much the most picturesque mountain range in the empire, follows the coast S. W. of Rio de Janeiro, traverses at variable distances from the shore the provinces of São Paulo, Santa Catharina, and Paraná, and about midway on the W. limit of that of Santa Catharina separates into two branches, one of which, under the name of Serra Geral, stretches across that province to As Torres, lat. 29° 20' S., and there turns westward, forming an elbow that trends first W., then N. W., with many curves, till, by a succession of low hills, it ultimately joins the Montes Yerbales in the Argentine Republic. The coast chain frequently changes its name; from Bahia to Rio de Janeiro it is called Serra dos Aymborés or Aimorés; in the latter province it takes the appellation of Serra dos Orgãos (Organ mountains), from a fancied resemblance to the tubes of an organ; it is next distinguished as the Serra de Paranapicaba, and lastly as the Serra Geral as above stated. The culminating point of the Serra do Mar occurs in the Organ mountains, and its height is estimated at from 7,500 to 7,800 ft. above the level of the sea. By far the loftiest mountains are W. of that chain. The Itatiaiossú, with an elevation of 10,800 ft., is the highest summit in Brazil; it is situated in the N. W. corner of the province of Rio de Janeiro, in the Serra da Mantiqueira, which separates from the Serra do Mar near the city of São Paulo, and skirts the coast for a distance much further N. than that range. In the Serra do Espinhaço are Itacolumi, 6,400 ft. above the sea; Itabira, 5,170 ft.; the Serra da Piedade, 5,770 ft.; the

Itambe, 5,903 ft.; and several others, all in Minas Geraes. On the frontiers of Minas Geraes and Goyaz is a mountain group called the Serra dos Vertentes (range of the watershed), which reaches its greatest height in the serras da Canastra, lat. 18° 30' S., and da Marcella, lat. 19° 10' S. This range consists of a series of spurs detached from that of the Espinhaço, stretching W. with numerous sinuosities nearly to the apex of the angle formed by the Grande and Parnahyba rivers, in Minas Geraes, lat. 19° 40' S. In the S. W. extremity of Matto Grosso, and almost in the same parallel as the Vertentes, originates a chain which, under the name of Serra de Santa Barbara, forms a considerable bend down to lat. 20° S. Thence it extends in a N. E. direction across the empire to the S. frontiers of Ceará; here it divides into two branches, one of which trends E. and loses itself between the provinces of Parahyba and Pernambuco before it reaches the coast, and the other, taking the name of Serra da Ibiapaba, forms to lat. 4° 30' S. the boundary between Piahy and Ceará. The whole of the range just referred to sometimes receives the name of Pyreneos; but this appellation is more properly confined to the ridge reaching from the city of Goyaz to Meia Ponte, and the highest points of which are, according to a Brazilian authority, about 9,620 ft. The Santa Marta, Santa Maria, and Tabatinga ridges, as the chain is successively called in its passage between the provinces of Minas Geraes and Goyaz, have no lofty peaks. The remainder of the chain, under the name of Serra da Borborema or dos Dous Irmãos, gradually diminishes in height until it is finally lost in the northeast. The entire range forms the watershed of the Araguaya-Tocantins, São Francisco, and Parnahyba rivers, and those of the northern tributaries of the Parahyba-Paraná systems, and of the N. W. tributaries of the Paraguay. The Araguaya basin is studded in its entire length with low hills, whose elevation above the plain is never more than a few hundred feet. Hilly regions extend N. and W. from the great coast ranges, and traverse the provinces of Minas Geraes, Goyaz, and Matto Grosso; but they are all of inconsiderable height. The hills from which descend the Iténez-Madeira head waters are but a continuation of the low Amazon-Paraguay watershed, and terminate in elevated marshy lands on the Bolivian frontier. It has been ascertained that the summit line in Brazil is close to the coast, and not in the interior, as has been erroneously presumed by most geographers and geologists; and this summit line is the E. edge of the Brazilian highlands, which descend by a gentle slope towards the west, and terminate in the great plains or flats of the Amazon basin, most of which are subject to periodical inundations. The N. boundary of the uplands is indicated by the cataracts in the large Amazon feeders, and forms a curve having for average latitude 5° S., and presenting its convex side to the north.

The S. boundary may be regarded as following the parallel of the Rio Iguaçu or Iguaçu. The surface of this extensive space is roughened by innumerable hills and some mountain ranges, whose elevation above the plain is, however, as has been seen, comparatively inconsiderable. There are no known volcanoes in the empire. Burton was informed that the Itatiaiossú in the Mantiqueira was of volcanic structure; but Hartt has strong doubts as to its being a volcano. —The territory of Brazil is watered by a large number of rivers, particularly in the north and south, the former constituting the basin of the Amazon, the latter that of the Plata, or more properly the Paraguay-Paraná-Plata. The E. portion, between the basins of the São Francisco and Parnahyba, is least supplied with rivers. The Amazon enters the empire from Peru at Tabatinga under the name of Solimões or Solimoes, holds an easterly course, takes the name of the Amazon or Lower Amazon at the junction of the Rio Negro, and falls into the Atlantic almost under the equator. The area drained by the Amazon and its tributaries in Brazil is 800,000 square miles. That part of the Amazon which forms the dividing line between Ecuador and Peru varies from half a mile to a mile in width; from Tabatinga to the junction of the Madeira it gradually widens to 8 m.; after contracting to less than a mile at Obidos, where it is estimated that 550,000 cubic feet of water pass per second, it expands in the next 75 m. to over 10 m. at Santarem on the Tapajós; near the mouth of the Xingú it is 20 m. wide; and it falls into the ocean through a single mouth 180 m. wide, including the Pará. Its depth is about 85½ fathoms at its mouth, and at São Paulo de Olivença near the Peruvian frontier; at the strait of Pauxis it reaches 254 fathoms; and the average depth is estimated at from 34 to 44 fathoms, so that vessels of any size may ascend to São Paulo throughout the year. The Solimões is in all seasons navigable by large steamers 1,400 m. from the mouth of the Rio Negro; and its basin is covered with one uniform, lofty, and impervious forest. Among the tributaries to the main trunk, starting from the mouth, we find on the left bank the Anarapucú, Gurupatuba, and Trombetas descending from the mountains which separate the empire from the Guianas. The Rio Negro, by far the largest and most majestic of the Amazon feeders from the north, enters the empire in lon. 67° 30' W., runs first S., then curves S. E., and, after a course of 1,200 m., pours its inky stream through two channels into the Amazon at Manáos, 1,000 m. from the ocean. The Negro is linked to the Orinoco by the natural canal Cassiquiare, navigable throughout. The Japurá or Caqueta flows almost parallel with the Ucayari-Negro, and after a course of over 1,000 m. falls into the Amazon through four mouths at the town of Ega. The Putumayo is the last large river on the left bank between the Negro and the Peruvian frontier. The

largest affluents of the Amazon come from the south. The first on the right bank, and which separates the empire from Peru, is the Javari, which it receives at Tabatinga. Next to the east is the Jutahi, which, with the Jurúá, Tefé, Coary (supposed to communicate with the Jurúá about lat. 9° S.), and Purús, has not yet been thoroughly explored. The Purús is believed by some to be the "Madre de Dios" of the old Spaniards, and navigable to the Bolivian frontier. The Madeira (so called from quantities of wood often seen floating down its stream), 2,000 m. long, enters the empire about lat. 11° S., and flows N. E. to its confluence with the Amazon in lon. 58 W. The Madeira rises and falls about two months earlier than the Amazon. The Tapajos rises in the Serra Diamantina, a few miles from the head waters of the Paraguay, and after a N. course of 1,100 m., navigable throughout for canoes, and for large vessels to a distance of 200 m. from its mouth, it blends its clear olive-green waters with the white turbid current of the Amazon just below the town of Santarem. The Xingú, some 300 m. longer than the Tapajos, rises in the same plateau, and runs parallel with it to the town of Boa Vista, where it joins the Amazon, here 25 m. wide. The few geographers who make the Rio Pará merely a mouth of the Amazon include in the number of the tributaries to the latter river the Tocantins, whose main branch has its head waters in the Serra de Sta. Maria, about lat. 15° S., and enters the Pará 40 m. W. of the city of Belem. The Tocantins is joined, 300 m. from its mouth, by the Araguaya, which is also a great river; indeed, it is the greater of the two, and has the longer course, and hence ought to rank as the main stream. The preceding are all the Amazon tributaries of importance. These present an unparalleled extent of inland water communication, reaching to every country in South America save Chili and Patagonia. They are divided into two classes, distinguished by the color of the respective streams, those of one class being black, those of the other class white. This difference in color is attributed to the great quantity of resinous matter held in suspension in the black-water streams, received from the coniferous trees which they carry in great numbers to the Amazon. The black waters are infested by large numbers of insects, and intermittent fevers and leprosy are more prevalent on their banks than on those of the white waters; the latter, on the other hand, are the more favorite haunts of the various large saurians. Descending the coast in a S. E. direction from the Amazon, the Paranhya is next encountered. It rises in the Serra de Tabatinga, and after a generally N. E. course of perhaps 1,000 m. falls into the Atlantic by six mouths, at the city of its own name, in lat. 3° S., lon. 41° 45' W.; it has numerous small affluents, and is said to be navigable for a distance of 780 m. The São Francisco, occupying the third rank among

the rivers of South America, and the sixteenth among those of the world, takes its rise in the highlands between lat. 20° and 21° S., and flows almost due N. to lat. 12°, where it bends N. E., and falls into the ocean some 30 m. S. E. of Penédo. In lat. 17° 11' 54" it receives the Rio das Velhas; in lat. 19° 10', the Pará; and about lat. 18° 49', the Paraopeba. The Rio das Velhas, the main branch, might by the removal of a few obstacles be made navigable by steam for 360 m. from its mouth. The bed of the São Francisco is much impeded by rapids and cataracts; otherwise the river would be navigable from the confluence of the Rio das Velhas to the sea. Steamers ply already from the Porto das Piranhas to the ocean; and Burton says that \$1,015,000 would be sufficient to open the two rivers, and construct a railway to avoid the cataracts at Paulo. Among the great southern arteries of the empire is the Paraná, formed by the united streams of the Paranhya and Grande (which receive their head waters from the mountains of Minas Geraes), and flowing S. W. by S., constituting the boundary line between the provinces of Matto Grosso and São Paulo, and Paraná and the republic of Paraguay. The Tieté, Iguaçu or Iguaçu, and a host of other rivers fall into the Paraná. The Paraguay flows almost due S., separating the province of Matto Grosso from Bolivia, from lat. 20° 20' S., and unites with the Paraná at the S. W. corner of the republic of Paraguay to form the principal feeder of the Rio de la Plata. The Paraguay is navigable from Villa Maria. The Mearim in Maranhão, the Piranhas in Rio Grande do Norte, the Belmonte or Grande in Bahia, the Doce in Espírito Santo, the Parapanema, separating the provinces of São Paulo and Paraná, the Jacuhy and Ibiçuy in Rio Grande do Sul, the Uruguay, which separates Paraná from Rio Grande do Sul, and the latter province from the Argentine Republic, with many others, are all rivers of considerable magnitude. The Amazon and some others of the Brazilian rivers are regularly visited at their mouths by the *pororoca* or bore. (See AMAZON, and BELEM.) Most of them are subject to periodical risings during the wet season, when they overflow their banks and inundate the surrounding plains over an extensive area. The flooding of the Amazon, however, offers no impediment to navigation, inasmuch as its affluents do not all swell simultaneously, but have their risings at intervals of six months on either bank of the trunk stream. The Amazon attains its maximum height in June, 55 ft., and its minimum in December, 32½ ft. The lakes of Brazil are numerous, especially in the provinces of Pará, Maranhão, Goyaz, and along the coast, from lat. 19° S. to the southern extremity of the empire, as also in Matto Grosso. The principal are the Lagôa dos Patos (lake of the Ducks), about 150 m. long and 40 m. wide, stretching N. to S. along the coast of Rio Grande do Sul; and the Lagôa Merim, lying S. of the former,

and much smaller. Though these lakes communicate with each other and with the sea, the water of the Lagoa dos Patos is but slightly brackish, particularly in the N. portions, where its waters are constantly freshened by the influx of several large rivers. The lakes of the coast region of Rio de Janeiro are very numerous, some being several leagues in diameter, but all exceedingly shallow. Lagoa Feia, the largest, is 20 m. long; and another, called Rio Iguaçu, 15 m. Elsewhere on the coast similar lagoons are common.—For a length of at least 2,000 m. along the coast of Brazil, and certainly for a considerable space inland, solid rock, wherever it occurs, belongs to a granitic formation. The serras do Mar and da Mantiqueira are wholly composed of gneiss of an orthoclase species, varying from schistose to coarse-grained and porphyritic or homogeneous and granitic. As one proceeds westward from the coast, the gneiss becomes finer, and finally gives way to heavy beds of mica slate, or mica-schistose gneiss with bands of quartz; and this same succession is said to obtain in most other parts of the empire. Strong lithological resemblances are observed between the gneisses of Brazil, which De Beaumont affirms to be among the very oldest stratified rocks on the globe, and the Laurentian rocks of Europe and North America; and this resemblance is still more strongly marked by the absence of mica slate in both formations. The exact succession of the different members of the metamorphic series in the gold-bearing region in Minas Geraes has not yet been thoroughly worked out. The clay and talcose schists, the itacolumite, itabirite, and other associated metamorphic rocks of this section are, in the opinion of Prof. Hartt, lower paleozoic in age. Some of these rocks, which resemble the auriferous rocks of Nova Scotia, may be Devonian; they have been everywhere so metamorphosed that all trace of fossils has been obliterated. Great numbers of fossil plants of carboniferous genera occur in the empire; the coal basins lie just S. of the tropic, but within the range of the palm; they are of coast formation; and carboniferous rocks also occur in the Rio Iténez. There do not appear to be any carboniferous strata on the coast N. of Rio de Janeiro, the depression of the shore allowing the accumulation of coal beds not having extended beyond the southern provinces. A thick series of triassic red sandstone, unassociated with trap, underlies the cretaceous rocks in Sergipe, and extends over a large area. Cretaceous rocks are found along the coast from Bahia to Pianhy, but none occur S. of the parallel of the Abrolhos; they are so largely covered by tertiary beds that it is difficult to estimate their extent; but it is quite probable that they underlie the tertiary deposits throughout the whole Amazon valley. They show themselves on the Aquiry, an affluent of the Purús, and have there been examined, as reported by Prof. Agassiz. The

cretaceous rocks seem to have been deposited in a shallow sea, have been very slightly disturbed, do not anywhere form remarkably high hills, and are at the Abrolhos associated with volcanic deposits. Prof. Hartt, though no fossils have been found in them, refers to the tertiary the clays and ferruginous sandstones forming the coast plains and overlying the cretaceous rocks unconformably, inasmuch as they are themselves overlaid by the drift clays that descend from the mountains and cover their glaciated surfaces. Drift occurs in Brazil, and is considered by Prof. Agassiz to be due to the agency of glacier ice.—The mineral productions of Brazil are immense; they comprise diamonds, sapphires, emeralds, euclases, rubies, topazes, aquamarines, zircon, gold, silver, copper, tin, lead, iron, and other metals. Diamonds have been found in various parts of the empire; but the great diamond region is in Minas, and extends from E. to W. between lat. 17° and 19° S., the most celebrated mines being those of the Serra do Frio. Diamond washing was formerly a monopoly of the government, but in pursuance of a recent law for the administration and working of diamond mines, these now belong exclusively to private individuals. The diamond usually occurs among the sands produced by the disintegration of the sandstone rock. Some of the largest known diamonds were found on some of the small rivers flowing into the São Francisco on the left bank, between lat. 18° and 19° S.; but search here has long since been abandoned. On one of these streams, the Abaeté, was found one of the largest diamonds of which we have any record; it weighed 188½ carats. From 1740 to 1772 the average diamond extraction per annum was 52,080 carats; but this average has since suffered an enormous annual decrease, and the total value of the diamond washings during the first 100 years, perhaps \$20,000,000 at the most liberal estimate, was far outstripped by the exportation of the single article of coffee in the year 1856, \$28,000,000. Diamonds are also met with in Paraná, near Cuyabá in Matto Grosso, and in the Patatinga district in Bahia. The annual production of diamonds in this province is perhaps \$3,000,000. The export of these stones from the port of Bahia in the year 1864-'5 amounted to nearly \$760,000, and that of sugar alone to almost four times that sum. The other precious stones above enumerated occur in Minas Geraes. Garnets, though not of the finest quality, are found throughout the whole empire; and beautiful amethysts are by no means rare. The gold of Brazil occurs in the metamorphic rocks, in drift gravels and clays, and alluvial sands and gravels. The formations richest in gold are clay slates traversed by auriferous quartz lodes, itacolumite rock veined with gold-bearing quartz, and certain iron ores variously known under the names itabirite and jacutinga. The richest gold mines in the empire are situated in the vicinity of Ouro Preto, in

the province of Minas Geraes. Here the metal occurs primarily in quartz veins traversing metamorphic rocks, and is also disseminated throughout the rock in many places. The principal mines of the Morro Velho, in the valley of the Rio das Velhas, a tributary of the São Francisco, are those of Cachoeira, Bahú, and Quebra Panella. According to Phillips, the net profits of these mines for 1849 were \$190,680; for 1861, \$488,845; and for 1865, \$404,190. In 1864 there was a loss of \$73,145. These mines are worked by a British company, and yield a dividend of \$10 per share of \$75. The mines of Gongo Soco, and some others formerly very productive, have been abandoned. The gold veins in the alluvial soils of Minas Geraes are usually associated with platina and iridium, and in other mines of a different geological formation in the same province with tellurium and other minerals. In some parts of the country it is always accompanied by and at times mixed with palladium to the extent of 7 to 11 per cent. The opinion that the gold mines of Brazil are exhausted is pronounced to be false by Burton, Liais, Hartt, and other authorities. Silver almost everywhere accompanies the galenic formation. Copper abounds in Matto Grosso and in São Pedro do Rio Grande do Sul; it is likewise found in the provinces of Minas, Bahia, and Ceará, and near Villa Viçosa in Maranhão. Tin has been discovered among the sands of the river Paraopeba in Minas, and in the province of Rio de Janeiro. Galena is frequently met with, composed as follows: lead, 86½ per cent.; sulphur, 13½; and silver, from 1 to 7 parts in 10,000 of ore. It is plentiful at the sources of the river Iguapé, in the district of Iporanga, and also at Sorocaba in São Paulo, and is found in the provinces of Minas, Bahia, Parahyba do Norte, Santa Catharina, Rio de Janeiro, and Ceará. Chromate of lead is found at Cogonhas do Campo in Minas Geraes. Sulphide of zinc and traces of native carbonate of zinc occur in Ceará. Arsenic accompanies the pyrites in some gold mines, and exists in the acid state combined with iron, forming scorodite, in the province of Minas Geraes. There are in Brazil iron mines entirely free from pyrites, thus, excelling even the famous mines of Danemora in Sweden. Iron works are carried on by the government at São João de Ipanema, the product being of excellent quality. Many varieties of granite of different colors occur in various localities, suitable for building, though for this purpose the various kinds of gneiss are commonly employed. A very compact quartz suitable for pavements is likewise found. Of porphyry, the green, pink, and black varieties (the latter containing crystals of feldspar) are abundant. Saccharoidal limestone occurs in many parts of the empire, and is generally eruptive in the gneiss formation. Of this class of rock there are several beautiful varieties. The limestone of the Rio das Velhas valley is of a dark gray color, and is so sonorous that in former times

plates made of it were used as bells for the churches. The lime used in building on the coast is almost exclusively made from the *sambauis* or enormous mounds of shells piled up centuries ago by the aborigines, or from the coral beds which abound in all the bays from the Abrolhos northward. Gypsum is found in Minas, Rio Grande do Norte, Ceará, Maranhão, and Amazonas. The various species of clays are extensively used for making bricks, and would also be very suitable for the manufacture of earthenware. There are extensive mines in Rio Grande do Sul, yielding coal with a more abundant ash than the English coals sent to Rio de Janeiro, which it resembles in appearance and general properties. Prof. Hartt says it has been used since about 1860 in the Jacuhy company's steamers, and found more economical than the English coal. A railway from the mines will carry the coal to a seaport, whence it can be taken by colliers and delivered at Montevideo in three or four days at about half the cost of delivering it at Rio de Janeiro, where nevertheless it is computed that it can be sold at about \$8 per ton. Coal also appears in São Paulo, and again in Ceará; it is supposed to exist in Piauhy and Maranhão, and in the valley of the Amazon. Lignite is found in São Paulo, and peat in almost all parts of the empire. Bituminous schists are also frequently met with, some being of a turfy origin. Near the mouth of the Camamú, yellow schists have been discovered which afford by distillation a solid matter analogous to naphthaline, and a very volatile carburet of hydrogen, possessing excellent illuminating properties. Similar schists exist in Maranhão. Graphite is plentiful in Ceará. Sulphur has been detected in Rio Grande do Norte. Nitre, alum, sulphate of magnesia, sulphate of soda in the efflorescent form, and rock salt occur in most of the provinces. Common salt is extracted from the *stomopoda* which come upon the rock in the Rio Negro below the fresh water, and in the strongest part of the current. A curious efflorescence is that of chloride of soda in the gneiss of some of the mountains of Ceará.—Among the fossil remains of extinct mammals found in Brazil may be mentioned those of the mastodon, species of *macrauchenia*, *toxodon*, *chlamydothierium*, and of the gigantic glyptodon (*hoplophorus*), *mylodon*, and *megatherium*. Among the carnivora there were wild cats and jaguars, and a species of *smilodon* (*S. neogaeus*), an immense cat-like animal with enormous knife-like canine teeth in the upper jaw, allied to the fossil European species. The *protopithecus* is the only extinct genus of monkey found. Lund encountered in the basin of the São Francisco stone implements and remains of man so buried with the remains of the extinct fauna as to leave no doubt that man was contemporaneous with it in Brazil as in Europe. Bones of an immense capybara (*hydrochærus sulcidens*) have been met with, and of llamas and horses, which

last certainly existed in Brazil, as in North America, long before the conquest.—The climate along the coast from about lat. 24° S. to the N. limit, and in the valley of the Amazon, may be described as generally hot, though some parts are subject to sudden and violent atmospheric changes. In the valleys of the Paraná and the Uruguay, as also on the highlands, a cool and even a cold temperature prevails; and the climate of the whole empire, though for the most part moist, is in general healthy. In the north the wet season (winter) begins regularly toward the end of November, and lasts till the middle of May; during this period the rains are abundant and usually accompanied by terrific thunder and lightning, and become more and more frequent and heavy as the end of the season approaches. On the Amazon, from Belem westward, rain falls almost every afternoon. At Belem there are but 60 days out of the year without rain. The thermometer in this region ranges from 98° to 68° F., while at Rio de Janeiro the average temperature is 75°, and still lower toward the south. In the northern provinces, from June to December, the *ventos geraes* (general winds) blow steadily in the daytime from the northeast, and during the night from the east. The most common diseases are pulmonary consumption, intermittent fevers, and rheumatism. Gout is extremely prevalent in Minas, parts of Bahia, and elsewhere, and is attributed to the saline impurities of the water. Leprosy is prevalent along the banks of the Amazon, at Rio de Janeiro, and elsewhere; it is said rarely to attack foreigners, and though generally reported to be incurable, statistics show that, in places where there are good physicians, it often yields to treatment, and permanent cures are effected.—The soil of Brazil is as varied as its climate, being in some parts amazingly fertile, and bearing almost every known species of vegetable production; while in others it is dry, arid, and unfavorable to vegetation. As a rule, the lands surrounding the large and populous cities are exceedingly rich and productive. The immense plains of the interior are for the most part covered with primeval forests, offering inexhaustible quantities of timber adapted both for solid construction and for cabinet and ornamental works. Few countries in the world contain such a quantity of vegetable matter on their surface as the valley of the Amazon; from a point about 60 m. S. E. of Tabatinga, a circle may be drawn of 1,100 m. in diameter, the whole area of which is covered with one dense mass of arboreal vegetation. Nearly 400 different species were exhibited in the *exposição internacional* at Belem in 1867; and Prof. Agassiz reports having seen at the same fair 117 different kinds of valuable woods cut from a piece of land not half a mile square, many of which were dark-colored veined woods, as beautiful as mahogany or rosewood, and susceptible of a high polish. Under the name of *jacarandá* or rosewood are known

several species of wood, all very hard and compact, of a blackish red tinge. They flourish in Amazonas and the provinces N. of Rio de Janeiro generally, that of Espírito Santo being reputed of a fine quality, and forming the principal article of export from the Doce. The *itaúba* or stonewood, found in great abundance in Amazonas, Pará, Maranhão, and other northern provinces, often attains a height of 100 ft., with a trunk over 6 ft. in diameter; all the best vessels of the Amazon country are constructed of this wood, which is said to be more durable than teak. The *copaíba* (*copaifera Guayanensis* or *officinalis*) and the *pao Brazil* or Brazil wood, the former valuable for its oil used in medicine and the arts, and also for its timber, the latter for its celebrated coloring matter, present a marked feature in the forest vegetation. The colossal *pao d'arco* or bow wood (*tecoma speciosa*) and *macaranduba* (*mimusops elata*) abound in the virgin forests N. of Rio; the timber of both is exceedingly hard and extensively used in carpentry and cabinet making. From the latter is extracted by incision a whitish, sweet, savory fluid, commonly used while in the liquid state as milk in tea and coffee; after some hours it coagulates, forming a white, elastic mass resembling india rubber, when it is employed in the arts; while the bark, very rich in tannin, is much used in dyeing. The total height of these trees, stem and crown, may be estimated at from 180 to 200 ft.; the vast dome of their foliage rises above the other forest trees as does that of a cathedral above the other buildings in a city; and logs 100 ft. long squared from these trees are not uncommon at the saw mills near Belem. The growth of buttress-shaped projections around the lower part of the stems, not only of the trees just mentioned, but of most of the larger trees, is a remarkable feature of the forest; the buttresses, generally thin walls of wood, form spacious stall-like compartments, often capable of holding half a dozen persons, and serve as props to the enormous stems. Of the order of *lecythidaceæ* there are some 40 species distributed among seven genera. Chief among these are the *sapucaia* (*lecythia Ollaria*), the fruit of which (*sapucaia nuts*) is closely allied to the Brazil nut, and is enclosed in a vase-like shell with a close-fitting lid, called a monkey cup, and the *Bertholletia excelsa*, a majestic tree forming whole forests, and producing the Brazil nut. The timber of these genera is especially valuable in constructions exposed to trying atmospheric action. To those already enumerated may be added the *augico*, *vinhatico*, *caixeta*, *sucupira*, *canella*, *pao ferro* (ironwood), *cedro*, *perobal*, *gonçalo* *aloes*, *bacuri*, *jiquitibá*, *condurú*, *piquiá*, *bracutiara*, and a host of others yielding timber suitable for every purpose, besides an endless variety of fruits, resins, oils, dyes, &c. The chief ornament of the forest is the palm, which is here represented by from 300 to 400 species, all more or less useful to the aborigines, and

some even necessary to their existence. From the graceful *cocos nucifera*, with its giant pinnate leaves often 20 ft. long, the *Maximiliana regia*, jará-assú, *manicaria saccifera*, *griarteia exhoriza*, *Leopoldina pulchra*, and some others, the Indian obtains food, drink, raiment, dwelling, hammocks, cordage, cooking utensils (the woody spathes of some palms standing the fire when they are filled with water), weapons, tools, fishing tackle, harpoons, implements for the chase, musical instruments, and medicines. The car-nohuba palm gives wax which, mixed with tallow, makes excellent candles, and a sort of farinaceous pith much used when other food is scarce. The cocos, of which the cocoanut palm is the type, and of which about a dozen species are here known, the assai, the bacába, a single bunch of whose fruit weighs from 30 to 40 lbs., the peach palm (*pupunha*), and scores of others, all furnish delicious and wholesome fruits, and some of them refreshing beverages. The cocos yield wax, oil, sugar, starch, and materials for cloth and cordage; the leaves and shells give thatch for huts, materials for hats, hammocks, mats, baskets, and other articles; and the roots, sap, flowers, and milk afford to the Indian medicinal remedies for many of his peculiar maladies. The wood of all the palms is very good for building. One of the most beautiful members of the palm family is the mirití, with its pendent clusters of reddish fruit, and enormous spreading, fan-like leaves, cut into ribbons, one of which is a load for a man. The plume-like leaves of the jupatí are often 50 ft. long, and those of the bussú 30 ft. All the well known tropical fruits can generally be had in any part of the country; but the interior abounds in productions utterly unknown in the coast districts. Some of these fruits have been cultivated by the natives, such as the jabuti-púbe and camá (two species), the former resembling the apple, the latter the pear in form and size, and both containing a pulp of a delicious flavor. The fruit of the *artocarpus Braziliensis* (Gom.), or Brazilian breadfruit, sometimes a foot and a half in the largest diameter, has immense seeds which are extensively used as food. Others grow wild, as the pamá, an oblong, cherry-colored stone fruit, growing at a height of 100 feet from the ground; and the purumá-i, which tastes like wild grapes. The fatty, bitter pulp of the umari and the wishí is eaten mixed with farina, and is very nourishing; and mingau (custard) of bananas, flavored with the mallet-shaped wiko—an oblong, crimson fruit, growing apparently crosswise on its stem—is a favorite dish on the Solimoens. All vegetation is much more luxuriant in the basin of the Solimoens than in that of the Lower Amazon; trees which near Belem bloom but once a year have flowers or fruit, and sometimes both, throughout the four seasons at Ega. The species of social plants are comparatively few in Brazil; those most noteworthy in the Atlantic regions are the mangroves, *conocarpus*

and *avicennia*, in addition to which and the *pteris caudata* are some species of *rhexia*, *cecropia*, and *bignonia*, together with the ubá, jaquarassú, some grasses, a bamboo, and the dwarf palm of the coast, *guri-rí*. The forests of the central provinces are made up of *melastoma*, conspicuous from their large purple blossoms; *bombaceæ*, with their peculiar foliage and large cotton fruits; candelabra trees, with a fruit resembling that of the bread tree (cultivated in Brazil), but slighter and more cylindrical; euphorbias of extraordinary size; the genera *ilex*, *laurus*, *myrtus*, *eugenia*, *jatropha*, *visinia*, *ficus*, as also the *bignonia*, *rhexia*, *lecythia*, and hundreds of other for the most part unknown species; and near the plantations and dwellings exotic tropical trees are everywhere cultivated. Luxuriant plant growth greets the eye in all directions; nowhere is a spot to be seen without plants. Numberless species of *passiflora*, *caladium*, *dracontium*, *piper*, *begonia*, and *epidendrum*, with multitudinous ferns, lichens, and mosses, bloom on every tree stem; and the mass of foliage is everywhere interlaced by parasitic vines. Countless tough, woody lianes, varying from thread-like tenuity to the thickness of a man's thigh, cling to and twine around the tree trunks, climbing to the very topmost branch, there to blossom and bear fruit above the reach of vision. The caoutchouc tree occurs chiefly between Belem and the Xingú, and on the Solimoens and Rio Negro; and the *smilax syphilitica*, valuable for the sarsaparilla extracted from its roots, abounds in the whole Amazonian forest region, from Venezuela to Bolivia. Brazilian nutmegs, Tonka beans, and Maranhão cloves are all common to the Rio Negro, in the basin of which are numberless trees rich in various kinds of oils and resins. Among the forest trees of the Amazon, the *leguminosæ* are by far the most abundant in species, and also the most remarkable, from their curious bean-like fruits, commonly of immense size or length. Many of the ingás and allied genera have pods a yard long and very slender, while in others the pods are three or four inches wide and quite short. There are numerous species of vanilla; the Leopoldina palm, the fibres of whose petioles give the piassaba so extensively employed in textile fabrics, occurs in large numbers; as do also several species of *bombax*, producing silk cotton. The flowers of the forest trees in the densely wooded regions are comparatively small and inconspicuous; in the open country, or *campos*, the flower-bearing trees and bushes are more abundant, as indicated by the larger number of floral insects attracted thither; but in the more cultivated districts in the central and southern provinces, the prodigious variety and beauty of the flowers never fail to command attention and admiration. In addition to the tropical fruits alluded to above, mention should be made of the bananas, yams, figs, lemons, oranges, &c., all of which grow

in immense quantities in most of the provinces, the oranges of Pará being at once remarkable for excellence and abundance.—The zoology of Brazil is no less remarkable than its botany for the variety of species which it comprises. Among the animals not indigenous to the country are the horse, ass, sheep, hog, and dog. Numerous herds of horned cattle roam wild over the vast plains of the interior, and considerable numbers in a domestic state on the large plantations of the southern and central provinces. The horses compare favorably with those of other South American states; but the sheep and swine are in general of inferior breeds, though the markets of the large cities afford some excellent mutton. Wild pigs inhabit the forests and are hunted for food. Game in great variety abounds throughout the wooded region, and especially deer, hare, and squirrels. Here also are the great maneless lion (cougar or puma); the jaguar, whose strength enables it to kill a young bull and drag the carcass to the summit of a hill; the ocelot (*felis pardalis*), and two other species of *felidæ*. All these the Brazilians designate by the single generic term *onça* (ounce), distinguishing them, however, into three species according to the color of the skin: the *onça preta*, *onça pintada*, and *onça de lombo preto*. Wolves, *cachorras do matto* (dogs of the woods), a species of fox, and *antas* (American tapir) are common; as are likewise sloths, *pacas* (*calogenys paca*), agoutis, and armadillos; the three last named species ranking among the most highly esteemed game of the country. Three small species of deer, the tapir, the largest quadruped in the empire, two or three species of large *felidæ*, two kinds of wild hog, the capybara, and the *paca* comprise nearly all the large game of this region. Small agoutis, sloths, armadillos, and ant-eaters are common. The capybara (*hydrochaerus capybara*) frequents the banks of the rivers, eats grass, and dives when pursued. Its flesh, though frequently eaten, is not very good, while that of the *paca* is particularly savory and tender. Many species of opossum occur, and are very destructive to poultry. The flesh of the armadillo, both species of which are eaten, is white and delicate. The large ant-eater is a powerful animal; the Indians assert that it sometimes kills the jaguar; and the various species of sloth are a favorite prey of the harpy eagle. Otters, the *echimys* (a kind of rat), two species of coati, porcupines, iráras or honey-eaters, water rats, and various other species of rodents are not uncommon. There are over 80 known species of monkeys in the basin of the Amazon, and probably twice that number in all Brazil; of these the *mycetes*, or howlers, are the largest; the coaitá and many other kinds are esteemed for the delicacy of their flesh. Rabbits are common in the central provinces; and vampires often cause much trouble by biting horses, cattle, and even men. Chief among the pre-

daceous birds are the king vulture and the harpy eagle, which, with a great variety of smaller eagles, hawks, kites, owls, &c., inhabit the Amazon region, and all but the first two are found in most parts of the empire. There are two other species of fine eagles inhabiting the Upper Amazon exclusively. Wallace reckons at least 80 distinct species of parrots, varying in size from the tiny *psittaculus passerinus* to the magnificent crimson macaw, and some 20 varieties of humming birds. Immense flocks of aquatic birds frequent the rivers and lakes; the American ostrich (*rhea Americana*) ranges from Ceará to the Uruguay; and there is an infinite variety of small birds, whose showy and brilliant plumage forms a gay contrast with the monotonous, never-fading verdure of Brazilian vegetation. During certain seasons of the year frigate birds, gulls, and several other species of marine birds resort in numbers to the Abrolhos. A remarkable bird is the sirienma, a sort of small ostrich, occurring in the highland deserts; it is easily tamed, and then becomes very useful for the extermination of serpents, which form its chief food. Five species of toucans inhabit the woods of Ega, all remarkable for the enormous size and light structure of their beaks, which are often two inches wide and seven long. Turkeys, geese, ducks, Guinea fowl, and other poultry are met with in every form; and wild turkeys, peacocks, wild geese, &c., are very numerous. Some travellers have spoken of a kind of lyre bird in Minas Geraes. Among the reptiles, the boa constrictor (*jibóia*), and the anaconda (*sucurujá*) come first in order. Wallace says the latter is decidedly the larger of the two; but both attain to an enormous size, and it is generally believed in the country that they sometimes reach from 60 to 80 feet in length. Poisonous serpents abound, and there are numerous varieties, the most terrible of all being the jararaca; it is common in all the southern provinces, and its bite, nearly always mortal, is immediately followed by the most poignant suffering. The jararacas-sú is a larger variety of the preceding. The *cobra coral*, or coral serpent; the *cobra sipé*, or liane snake, dangerous from the grayish color of the skin, similar to that of the lianes around which it entwines itself to lie in wait for its prey; the *cobra fria*, or cold snake, whose body is frigid as ice; and the rattle-snake (*cascavel*), are all exceedingly venomous, and rarely exceed two yards in length. Three or four distinct species of alligators abound in the Amazon and all its tributaries. The smaller ones are eaten by the natives, and they in their turn are devoured by the large ones. Besides the jurará, the largest and most abundant of the Brazilian turtles, there are various other species; from their eggs, the yolks of which are very good eating, is extracted an oil much used for light and in culinary preparations. The rivers and lakes abound in fish of endless variety; in every small river, even in different parts of the same river, distinct species occur;

and it would be impossible to estimate the number of kinds in the several rivers of the empire. The garoupa is a large fish, of excellent flavor, taken in prodigious numbers off the coast between lat. 17° and 18° S. An immense variety of fish is caught in the vicinity of the Abrolhos, and used for food, comprising some of the most delicious kinds of marine fish. The *peixeboi*, or cow fish, called by the Indians *jurud*, is an herbivorous cetacean, of which there are probably two species in the Amazon, considered as distinct from the manatee of the West Indies. In the São Francisco there is a fish called the piranha, exceedingly voracious, biting the legs of bathers, and attacking and mutilating other fish irrespective of size. The pirurucú is taken in large quantities in the Amazon, and is preserved like cod. The Amazonian forests are without a rival for the great size and gorgeous colors of their butterflies, and the endless variety of the species. The *heliconi*, a group of butterflies peculiar to tropical America, are very numerous; and the harlequin beetle, with the gigantic *prioni* and *dynastes*, are also found here. Musical crickets; immense spiders, of sufficient size (some being half a foot in expanse) and strength to attack and kill finches; countless varieties of bees, some without stings, others making sour honey; saúbas, or leaf-carrying ants, so abundant in some districts as to render agriculture almost impossible; formidable mosquitoes, sand flies, motucas, piums (a minute fly, the insect pest of the Upper Amazon), carnivorous beetles, huge scorpions, and myriads of other species, form the characteristic features of the Brazilian insect world.—There exist in Brazil magnificent pasture lands eminently suitable for cattle raising, and watered by great rivers affording an easy and direct highway to all the markets of the country and of the world. The meadow lands of the more southerly provinces, however, support countless herds of horned cattle, which form an important source of wealth to the country. The cultivated ground from the Rio Negro to the Andes does not exceed a few score acres. In the valley of the Tocantins the inhabitants like better to gather nuts and cacao, and make india rubber, than to apply themselves to the regular cultivation of the soil. That part of the coast region extending from Bahia to Sta. Catharina, with the exception of Espirito Santo, is generally devoted to coffee culture, though rice is an important product of Rio de Janeiro and the adjoining provinces, and there are immense sugar *fazendas* in all of them. The region embracing Rio Grande do Sul, Paraná, and Sta. Catharina yields the various cereals, cattle raising being likewise an important industry; and the great equatorial districts are characterized by the spontaneous products of the forest—barks, gums, resins, and textile substances as yet unknown in foreign markets—india rubber, sarsaparilla, cacao, vanilla, &c. Rice is easily raised in all parts of Brazil; cot-

ton yields large crops in almost all the provinces, as do also sugar and tobacco. Agricultural operations are chiefly centred upon coffee, cotton, sugar, tobacco, mandioca, the various European cereals, beans, and cacao, of which last there are extensive plantations in the provinces N. of Rio de Janeiro. The yield of sugar is still considerable, and has not materially increased or decreased since 1862, notwithstanding the preference given of late years to coffee planting in many districts. Four fifths of the coffee consumed in the United States, and over half of all that is used in the world, is of Brazilian growth. Yet Brazilian coffee is much underrated, for the reason that the finer qualities are nearly always put into market under the name of Java or Mocha, or even Martinique or Bourbon, although the yearly produce of coffee in the islands of Martinique and Guadeloupe would not be sufficient to supply the Rio de Janeiro market for a single day. Each tree is supposed to yield annually, on an average, two pounds of coffee; but some give as much as eight. Besides the provinces adjacent to Rio de Janeiro, the coffee plant flourishes in the shade of the Amazon forest, and with moderate care yields two annual crops; and the Ceará coffee, much esteemed, grows on the mountain slopes, at an elevation of from 2,000 to 3,000 ft. above the sea. In the province of Pará the coffee plant is seen growing on almost every roadside, thicket, or waste. In 1818 all the coffee exported from Brazil was only 74,800 sacks; in 1871 it was 2,358,001 sacks. The value of cotton exported increased from \$8,383,705 in 1862 to \$24,080,325 in 1866. This rapid increase was due to the civil war in the United States. Mandioca or cassava is extensively cultivated; it is said that one acre of it affords as much nutriment as six of wheat, and the farina prepared from it is a common article of food in all parts of the empire. The vine and the olive are cultivated to a limited extent in the southern provinces.—Manufactures are not yet in a very advanced condition in Brazil. Sugar refining is carried on extensively, particularly in the great cane-growing provinces of Bahia and Pernambuco, where there are numbers of *engenhos* established on a grand scale, with the best modern machinery for water or steam power. In the interior the old imperfect systems are still adhered to, owing in many cases to the apathy of the planters, but chiefly to the expense and difficulties attending transportation from the coast. Little has as yet been done in Brazil toward manufacturing this class of machinery. To the *engenhos* in the interior are commonly attached distilleries, and three kinds of rum are manufactured: *cachaça*, somewhat resembling in taste the rum of the West Indies, but inferior to that in quality, is in universal use among the lower classes, and is made from the molasses that drips from the *mascavado* or common raw sugar; *agoardente*, or the rum

of commerce, directly distilled from the cane juice; and *restilo*, the result of a second process of distillation (hence the name) of the latter, to which is previously added another ingredient. About 6,500,000 gallons of rum are annually exported. The *aguardente* is extensively used in the manufacture of gin and of fine liqueurs, a large variety of which latter, flavored with the aromatic extracts of various indigenous fruits, was exhibited in Paris in 1867. A sort of brandy is also made from *mandioca*, the fruits of the *cajueiro*, *genipapeiro*, &c. Beer breweries, of comparatively recent establishment, are in successful operation in Rio de Janeiro, Petropolis, Rio Grande do Sul, and Pernambuco; but the full development of this industry is seriously impeded by the necessity of importing from Europe the barley and hops, which might be raised in abundance in the southern provinces. Tobacco is manufactured on a large scale in some places, chiefly in Bahia and Rio de Janeiro, where are made several kinds of snuff much esteemed in foreign markets. Large quantities of cigars of a common class (*charutos*) are manufactured in Bahia and other places. In some towns and districts near Bahia the whole population is thus occupied, and the saw mills turn out from 7,000 to 8,000 cigar boxes a day. In the financial year 1859-'60 46,000,000 *charutos*, valued at \$304,667 55, were exported from Bahia; and the yearly export has since been steadily on the increase. A number of cotton-weaving factories have been established, and compete favorably with foreign manufacturers in the production of the coarser fabrics. The first cotton factory in Brazil was built by an American near Rio de Janeiro, and the workers are chiefly taken from the German colony at Petropolis. There is besides an extensive *fabrica* in the province of Bahia, also built by Americans, and employing 300 operatives of both sexes, mostly from the orphan and foundling asylums of the city. From 30,000 to 40,000 pieces (of 16 yards each) are here produced annually, and a considerable quantity of sewing cotton, nets, &c. The largest factory is in Minas Geraes, with 15,000 spindles and 400 looms; it affords constant employment to 800 hands, and is said to turn out annually 3,500,000 yards of cloth and 274,000 lbs. of yarn, of a total value of \$1,100,000. In the provinces already mentioned, and in Alagoas and elsewhere, there are other cotton factories, but of minor importance. To promote the development of this industry, the government has decreed the free entry of all machinery for that purpose, and the exemption of the operatives from military service, but appoints an inspector to superintend each establishment. Very good silks are made at Rio de Janeiro and elsewhere. There are saw mills in various parts of the country. Common and wall papers are manufactured; also soap, chemicals, braids, ribbons, bronzes, &c. Some important works have been executed in Brazilian foundries, such as steamships and iron

bridges; and the coast steamer companies have well appointed machine shops for the repair and even building of engines. The province of São Paulo has some large iron works. In the large cities there are gold and silver smiths and jewellers; but these and the artisans of the various other mechanical branches are mainly foreigners. In Brazil the exaggerated appreciation of political employment everywhere prevailing amounts to a national misfortune. Every man of liberal education seeks a political career, as being at once the easiest and most aristocratic mode of gaining a livelihood. The possession of a sugar plantation is regarded among the cultivators as a sort of nobility.—The chief article of export from Brazil is coffee, supplying, as before stated, more than half the consumption of the world. Among the other products sent in large quantities to foreign countries are cotton, sugar, cacao, hides, horns, tobacco, india rubber, diamonds, &c. The principal imports are cotton and woollen fabrics from Great Britain; wrought and unwrought iron from various countries; wines from Portugal, Spain, and France; agricultural implements, hardware, lard, flour, timber (pine), petroleum, biscuits, coal, ice, hams, soap, boots and shoes, &c., from the United States. The value of the total exports and imports for the three years 1866-'9 is shown in the following table:

YEARS.	Exports.	Imports.
1866-'67	\$78,000,000	\$71,750,000
1867-'68	92,650,000	70,300,000
1868-'69	101,350,000	83,850,000
Total	\$272,000,000	\$225,400,000

The entire quantities of coffee, sugar, cotton, hides, and horns exported from 1857 to 1870 inclusive, are as follows:

YEARS.	Coffee (sacks).	Sugar (boxes).	Cotton (bales).	Hides.	Horns.
1857....	2,099,780	7,317	81,485	818,081
1858....	1,830,433	10,620	61,147	288,981
1859....	2,080,266	7,785	81,297	838,661
1860....	2,127,219	3,235	67,208	814,716
1861....	2,069,627	12,335	79,512	170,586
1862....	1,485,220	12,818	70,815	115,498
1863....	1,850,109	9,722	68,944	283,237
1864....	1,480,184	7,136	85,129	180,178
1865....	1,801,952	4,622	90,716	119,980
1866....	1,984,986	6,042	100,198	75,608	191,288
1867....	2,547,658	6,287	70,967	70,141	116,860
1868....	2,265,155	5,155	118,128	88,709	265,544
1869....	2,564,975	8,501	45,055	85,865	147,446
1870....	2,209,456	6,540	17,910	61,507	165,909

EXPORTS TO THE UNITED STATES, FROM 1867 TO 1871 INCLUSIVE.

ARTICLES.	1867-'68.	1868-'69.	1869-'70.	1870-'71.
Cotton, lbs.	86,850	28,296	25,800
Sugar, lbs.	10,447,741	83,639,921	24,145,831	21,553,500
India rubber, lb	5,550,660	4,449,980	5,234,234	5,702,195

Horse hair, lbs.	586,151	973,546	741,054	923,863
Wool, lbs.	1,441,868	2,055,259	8,287,097	2,538,313

VALUE OF IMPORTS FROM THE UNITED STATES,
FROM 1867 TO 1871 INCLUSIVE.

YEARS.	U. STATES PRODUCTS.		Transhipped.	Total.
	Am.Bottoms.	For.Bottoms.		
1867-'68	\$3,025,411	\$2,619,618	\$197,859	\$5,842,888
1868-'69	2,805,297	3,106,268	158,514	6,070,079
1869-'70	2,988,191	2,719,170	110,485	5,817,846
1870-'71	3,899,069	2,546,298	148,757	6,089,154

Of the 2,209,456 sacks of coffee exported in 1870, the United States took 1,373,654. In the first half of 1871 there were shipped 1,253,656 sacks, 645,749 to the United States; and the same country took 371,266 out of a total of 625,429 sacks exported during the first half of 1872—a decrease in the total export of nearly one half. The value of the exports to Great Britain for 1870 was \$30,637,240, and of the imports \$26,834,170. The value of the British cotton manufactures imported in 1869 and 1870 was almost exactly covered by that of the raw cotton exported to the United Kingdom during the same period. From a comparison of the trade returns of several years, it is observed that one fourth of the exports go to England, and about one fifth to the United States, the remainder being divided between France, Portugal, Germany, and the Argentine Republic. The port movements in 1870 were as follows: entered, 3,540 sea-going vessels, with an aggregate of 1,436,000 tons; 4,903 coasters, tonnage 1,091,000; cleared, 3,215 sea-going vessels, tonnage 1,500,000; 4,994 coasters, tonnage 1,198,000. A line of clippers between Genoa and Rio Grande do Sul was organized in 1872, with vessels of 500 tons burden, but of light draft, to suit the bar of the latter port. The post-office receipts in 1865-'6 were \$209,902; by 1869 they had increased one-half; the expenditure for that period averaged only \$358,286 annually.—Save in the immediate neighborhood of the capital and other large cities, the want of adequate highways is still sensibly felt, and notably impedes the development of trade and industry, especially in the interior provinces. There are a few exceptions to this rule, however; and the department of agriculture and public works is devoting unremitting attention to this all-important subject. Lines of railway are fast multiplying in all the coast provinces; those already established are in process of extension, and new ones are projected. In the course of 1872 privileges were granted by the legislature for the construction of 12 lines of railway, with a telegraph system attached to each. The railway network penetrates the central provinces, from the capital to Belem in one direction, and to Rio Grande do Sul in the opposite, so that probably by the end of 1874 the traveller can proceed by rail from the Amazon to Uruguay almost without change of train. An important line is about to be built (1873) chiefly for carrying coals from the Candiota mines to the coast at Sta.

Catharina. The railways existing in 1872, with their respective lengths, and the receipts and outlays in 1869, are shown in the following table:

LINES.	Miles.	Receipts.	Expenditures.
São Paulo	87	\$1,143,526	\$428,368
Bahia	80	158,189	182,447
Pernambuco	80	424,400	263,360
Dom Pedro II.	140	2,812,908	1,072,581
Cantagallo	21	129,019	84,685
Mauá, or Petropolis.	11	250,581	91,832
Total	419	\$4,418,878	\$2,118,523
Total in 1869	3,214,859	1,662,375
Increase	\$1,204,014	\$456,148

An unusual outlay for repairs, together with a marked diminution of traffic, owing to deficient crops caused by disease in the sugar cane and the drought, gave rise to the deficit in the Bahia line. Of the foregoing lines, the most important is that of São Paulo, from Santos to Judiaby, deserving of especial notice from its prosperous condition, due to the wealth of the province which it traverses. On Oct. 1, 1872, a line was opened from Macaé in Alagoás to the interior. There were at the end of 1872 nearly 1,600 m. of telegraph in operation; and the laying of a line from São Pedro do Rio Grande do Sul to Montevideo was commenced about the same time. A privilege was granted in 1872 for laying a submarine cable from Rio de Janeiro to Portugal, and the work was to be commenced immediately. The city of Rio de Janeiro is thoroughly permeated with lines of street railroads; in other cities lines have likewise been constructed, and prove of material benefit to the community, especially in a social point of view, having been instrumental in eradicating abuses under which Brazilian society has long groaned. Brazilian women, until lately condemned to a sort of Turkish seclusion, rarely going into the street, and never unaccompanied by father, brother, or husband, now travel alone in the street cars, and the custom is fast gaining ground. The great natural highways of Brazil, its majestic rivers, will afford an easy outlet for the productions of the interior, and a commencement has been made in turning these facilities to account. Weekly and even daily lines of steamers ply on the Amazon from Belem to the various towns along the course of that river. The Negro is navigated to a comparatively limited extent; steamers run regularly on the Araguaya-Tocantins from Belem to Goyaz; and vigorous measures are in progress to establish steam navigation on the São Francisco. Steamers ply constantly up the Paraguay (navigable through nearly the whole of its course) to Cuyabá, the capital of Matto Grosso, that being still the only route by which the province is readily accessible. A new survey of the Amazon at the expense of the imperial government was ordered in 1872, a preliminary step to the still further increase of steam facility on that river.

The English, on the one hand, have taken up steam navigation on the Amazon, so long carried on by a Brazilian company; and on the other, American enterprise is penetrating the Madeira and Mamoré to open up steam communication with the interior of Bolivia; and railroads will be built wherever navigation is impeded by insurmountable obstacles, such as the falls of the Madeira. Before the introduction of railways, the traffic between the coast and the interior was imperfectly carried on by mule trains, which is still in a large portion of the country the only available method.—There are in Brazil 19 banks and innumerable private banking houses. Chief among the former are the *banco do Brasil*, do Bahia, de Campos, Commercial do Rio Janeiro, do Maranhão, do Pernambuco, do Rio Grande do Sul, do Pará; and the English of Rio de Janeiro, limited, London and Brazilian, Brazilian and Portuguese, the *banco Rural e Hypothecario*, and the bank of Mauá and co. The *sociedade economica de consumo*, having for its object the establishment of cheap shops, has a capital of \$150,000 in \$50 shares. The Mercantile Industrial bank of Rio, established in 1862, has a capital of \$10,000,000, in \$100 shares.—Brazil is governed by a hereditary and constitutional monarch. The constitution is based upon the fundamental law of March 25, 1824, modified by additional acts of Aug. 12, 1834, and May 12, 1840. The constitution establishes four powers in the state: the legislative, executive, judicial, and the “moderating” power, or royal prerogative. The legislative power is vested in a national legislative assembly and in provincial assemblies. The national assembly consists of two houses, senate and congress. The senators, 68 in number, are elected for life; and the representatives, 122 in number, are chosen by the whole of the free population (save minors, monks, and servants) for four years. Senators must be native Brazilians, have attained the age of 40 years, and possess an annual income of at least \$800. They receive a salary of \$1,800 for each session. Representatives are chosen by electors appointed by voters, every 30 voters having the privilege of naming an elector in each electoral district. The salary of the representatives is \$1,200 for each session, besides travelling expenses. The executive power resides in the emperor, assisted by his ministers and a council of state. The ministers are responsible for treason, corruption, abuse of power, and all acts contrary to the constitution; which responsibility cannot be evaded on the plea of orders from the sovereign. The latter has the power to convoke the ordinary meetings of the legislative assembly; nominate bishops, presidents of provinces, and magistrates; declare peace or war; and to sanction and superintend the execution of all measures voted by the legislature. By virtue of the “moderating” power, the sovereign can choose ministers and senators, withhold temporarily his sanction

from legislative measures, convoke extraordinary legislative assemblies, dissolve the house of representatives, and grant amnesties and pardons. The ministry is composed of seven departments: interior, foreign, finance, justice, war, marine, and agriculture, public works, and commerce. The council of state is composed of 12 ordinary and 12 extraordinary members, appointed for life by the sovereign. These councillors are for the most part ex-ministers; and the heir apparent to the throne, if of age, is by right a councillor of state. Each provincial government consists of a provincial chamber and a general council or legislative assembly. The members of the chambers are elected directly by the voters for two years; while the assemblymen are chosen by the same electors as the members of the national congress, their functions for the affairs of the provinces being analogous to those of the representatives for the affairs of the empire.—The army in time of peace is composed of 21 battalions of infantry (16,163 men), 5 regiments of horse (4,152 men), 1 regiment of artillery (5 battalions, and 1 battalion of engineers, 4,326 men); in all, 24,641 men, to which may be added 641 men forming a special corps. The strength in time of war is 73,784 men. The navy consists of 18 ironclads, 27 corvettes, 2 gunboats, and 7 transports, all steamers; besides which there are 33 sail of the line; making a total of 87 vessels, mounting 316 guns, and manned by 7,901 men. There are 6 vessels without armament, and a number of ironclads and other vessels of war were in course of construction in 1872. The total strength of the navy is 8,393, distributed as follows: 18 general staff officers, 545 first-class officers, 142 second-class, 101 forming a sanitary corps, 234 accountants, 62 boys, 132 engineers, 3,268 imperial marines; naval battalion, 1,275, and apprentice marines, 2,616.—The expenditure of the empire from 1855 to 1859 was as follows: 1855-’6, \$20,120,000; 1856-’7, \$20,187,500; 1857-’8, \$25,877,500; 1858-’9, \$26,859,000. After the Paraguayan war commenced, the expenditure increased as follows: 1864-’5, \$43,243,280; 1865-’6, \$60,930,929; 1866-’7, \$60,556,782; 1867-’8, \$75,523,870; 1868-’9, \$82,995,703; 1869-’70, \$73,189,858; 1870-’71, \$53,266,047. The amount to be disbursed in 1872 for emancipation annuities was estimated by the minister of finance at \$500,000; and that for 1902, when slavery is to cease, at \$8,000,000. About one fifth of the ordinary revenue is derived from land licenses and other taxes, such as that on transfer of property, &c.; more than one half proceeds from duties, export as well as import, the former being 18 per cent. on coffee and 9 per cent. on all other articles. From 1865 to 1870, when deficits were of frequent occurrence, these were covered by loans raised and bonds and paper money issued by government, and treated in the finance accounts as extraordinary receipts. The total receipts for the

financial year 1864-'5 were \$29,733,838; and for the year 1871-'2, \$46,884,316. The expenditure in 1871-'2 was as follows:

Ministry of the Interior:		
Civil list.....	\$699,735	\$2,564,060
Legislative Chambers.....	375,640	
Sundries.....	1,488,645	
Ministry of Justice.....	1,718,764	
Finance.....	19,712,587	
Foreign Affairs.....	408,909	
War.....	6,316,653	
Marine.....	4,424,186	
Commerce, Agriculture, Public Works, &c.....	6,004,258	
Total.....	\$41,154,422	
Receipts in 1871-'2.....	\$46,884,316	
Expenditure in 1871-'2.....	41,154,422	
Surplus.....	\$5,729,894	

The revenue has been steadily increasing since 1864, at the rate of 75 per cent. approximately; while the increase of the ordinary expenditure in the same period has not exceeded 20 per cent. The indebtedness of Brazil to England in 1862 was \$25,000,000, the foundation of which had been laid by loans to cover old charges of the colonial time, the war with Uruguay, payments of indemnities to foreign nations, and to cover deficits originating from year to year; and in 1872 the amount reached \$300,000,000, exclusive of railway guarantees, being an increase of \$275,000,000 in ten years. A loan of \$15,000,000 was contracted in February, 1871. In 1872 the following were the constituent elements of the national debt:

Foreign debt.....	\$300,000,000
Internal debt, at 4, 5, and 6 per cent.....	140,228,450
Debt prior to 1827.....	178,587
Orphans' funds and deposits.....	12,496,773
Paper money.....	73,599,081
Total.....	\$528,442,796

The issue of the 4½ per cent. loan of 1860 amounted to \$6,865,000; of that sum, \$2,266,500 was redeemed on June 1, 1872, leaving \$4,598,500 still to be reimbursed by the operation of the accumulative sinking fund. Besides the general receipts, there are the provincial and municipal receipts; the former amount to \$11,500,000, the latter to \$2,500,000. A credit extraordinary of \$136,500 was opened to the ministry of agriculture in 1872, to meet the expenses of the national exhibition to be held in Rio de Janeiro. The aggregate customs receipts of the empire in 1868-'9 were \$31,746,774.

—Public education has not yet reached a high point of development in Brazil; but numerous schools have been established of late in the provinces, and the government is engaged in developing and strengthening a general system. There are at present 4,437 schools in the empire; 3,603 being public and devoted to primary and secondary education, and 834 private schools. The number of secondary schools is in the proportion of one for every 18 primary; and there are twice as many schools for males as for females. The average annual cost of each public school is \$467; and the whole of the public schools cost annually \$1,681,000, or

nearly 15 per cent. of the average annual revenue of all the provinces. In each of the latter there is one private primary school for every five public, and one school for every 2,404 inhabitants of all classes and colors; and these schools are attended by an average number of 305 children. The total number of scholars enrolled is 133,950, 125,867 of whom receive primary, and 8,083 secondary education. These figures show a marked improvement as compared with the returns of former years; in 1868, only 107,483 children attended school in the whole empire, or 26,467 fewer than at the present time. There are two faculties each of law and medicine maintained at the expense of government; the imperial academy of medicine has an annual subsidy of \$1,000. Besides these there are 11 seminaries for the education of the clergy, subsidized by the state, a central college, an academy of arts, regimental and preparatory schools for the army, and a school of artillery. The whole educational system is under the jurisdiction of the minister of the interior and the control of the general assembly. The English merchants of Rio de Janeiro subscribed \$6,500 in 1872 for the establishment of a gymnasium for the use of the English-speaking young men resident in that capital. An annual subsidy of \$3,500 is given by government to the geographical and historical institute of Rio de Janeiro. Besides the libraries connected with the various public scientific and literary establishments, there are in Rio de Janeiro 11 public libraries, chief among which is the *gabinete portuguez* possessing 50,000 volumes, and being visited on an average by 2,314 persons yearly. By the provincial law of Dec. 26, 1871, the creation of libraries in all the cities of Rio de Janeiro was authorized; and there are libraries in most of the other provinces of the empire. There are dramatic and musical conservatories, an academy of fine arts, and other institutions for the promotion of literature, art, and science. The astronomical observatory of Rio de Janeiro was the object of important modifications in 1872.

—The religion of the state is the Roman Catholic. The whole empire constitutes one "metropolitan province," under the archbishop of Bahia. There are 12 dioceses: Bahia, São Sebastião (Rio), Olinda (Pernambuco), Maranhão, Grão Pará, São Paulo, Mariana (Minas Geraes), Goyaz, Cuyabá (Matto Grosso), São Pedro do Rio Grande do Sul, Ceará, and Diamantina (Minas Geraes). Over these dioceses preside one archbishop and 11 bishops. Brazil is divided into 1,299 parishes, most of the vicars of which are foreigners, chiefly Portuguese. Although the Roman Catholic is by law constituted the religion of the state, all other religions are tolerated, but restricted in their worship to buildings "without the exterior form of temples." In Rio de Janeiro and elsewhere there are Protestant churches; and the ministers of the Swiss and German colonies are paid by government. The United States Presbyterian

board of foreign missions maintain a mission in Brazil, with ten ministers and three churches in each of the cities of Rio de Janeiro and São Paulo, and some in Bahia. Their communicants number 847, nearly all native Brazilians. —Pedro Alvares Cabral, having been appointed admiral of a fleet sent by King Emanuel of Portugal to follow up the brilliant discoveries of Vasco da Gama in the East Indies, set sail March 9, 1500; but the fleet having been carried by ocean currents and adverse winds far to the westward of the intended course, Cabral on April 22 unexpectedly found himself in sight of land; and on the 25th the squadron cast anchor in a commodious harbor which the admiral named Porto Seguro. Cabral immediately took possession of the country in the name of his sovereign, calling it Vera Cruz, a name afterward changed to Santa Cruz, which in turn gave place to the present one of Brazil. This formality concluded, he once more set out upon his voyage eastward, but not without having previously despatched to the king tidings of his discovery. On the arrival of the news, a squadron was fitted out under the command of Amerigo Vespucci to visit and explore the new country; and that navigator on his return to Portugal published an account of his explorations with a map, to which publication is due the name America given to the whole western continent. Vespucci on his return carried some specimens of Brazilian birds, and a cargo of dyewoods, whole forests of which he reported as existing in the newly found country. These dyewoods immediately became the object of an extensive and lucrative traffic on the part of numerous speculators. Merchants of other nations having engaged in the trade, King John III. determined to suppress what he regarded as a violation of his rights. Colonies were accordingly established under the auspices of the crown in 1531, towns sprang up rapidly along the coast, and fortune for a few years seemed to smile upon the new settlements. But the colonists had suffered much from the frequent incursions of the savages; the pecuniary resources of the Portuguese nobles who had received land grants from the government, and full judicial powers, on condition of establishing the colonies at their own expense, soon proved inadequate to the enterprise; and it was deemed advisable to form a permanent system of colonial rule, immediately dependent upon the home government. A governor was accordingly appointed in 1549, in the person of Thomé de Souza, who was invested with unlimited powers of jurisdiction, both civil and criminal, and under whose wise administration the home government in a short time recovered possession of the early colonies, or *capitanias*. De Souza founded and took up his residence at São Salvador da Bahia, which was then constituted the capital of Brazil. A colony of French Protestants was founded in 1555 on an island in the bay of the present Rio de Janeiro; but the perfidy of the founder,

Vice Admiral Villegagnon, and consequent internal dissensions, marred the success of the settlement; and the colonists were expelled from the island in 1565. The Portuguese in 1567 built the city of São Sebastião, since called Rio de Janeiro, the name given to the bay by Martin Affonso in 1531. After the annexation of Portugal to Spain under Philip II. in 1580, Brazil found numerous enemies among the nations then on hostile terms with the latter kingdom; the coast towns suffered much from the successive inroads of the French, English, and Dutch, by whom they were in turn occupied, pillaged, and abandoned. In 1612 the French took possession of Maranhão, and founded the city of São Luiz do Maranhão, from which they were driven by the Portuguese in 1615. But the Dutch were the most pertinacious in their endeavors to secure a firm foothold in Brazil. A fleet from Holland in 1623 captured the city of Bahia; but in 1625, after the departure of their ships, the conquerors were forced to capitulate. In 1629 the Dutch took Pernambuco, and they extended their conquests with so much energy that in 1645 they ruled the whole territory N. of that city except Pará. The Portuguese, however, recaptured province after province, and in 1654 had completely driven out the Dutch, who by the peace of 1660 renounced all claim to Brazilian territory. In the mean time the house of Braganza had been restored to the throne of Portugal, in the person of John IV., Brazil erected into a principality, and the title of prince of Brazil conferred upon the Portuguese heir apparent (1640). From the time of the evacuation of the Dutch, Portugal remained in peaceful possession; but the exactions of the mother country drained the colony of its resources and retarded its development. Meanwhile the mineral riches of Brazil had been discovered; gold and diamond mining were in active operation, and poured a constant stream of wealth into the home treasury; and the Lisbon government constituted Rio de Janeiro the capital instead of Bahia. In 1807, when Napoleon declared war against Portugal, John VI., its reigning sovereign, took refuge with his family in Brazil, followed by a large number of courtiers and other emigrants. This event was immediately attended by important modifications in the colonial administration; restrictions upon commerce were removed; the ports were thrown open to the shipping of all friendly nations; and on the fall of Napoleon in 1815 Brazil was raised to the rank of a kingdom, John assuming the title of king of Portugal, Algarve, and Brazil. During his absence from Portugal a revolution had broken out there, and the constitution of Spain had been proclaimed, September, 1820; and as that example had been followed in Pará and Pernambuco, the king, fearing that the revolutionary movement might extend to Rio de Janeiro, took himself the initiatory steps, and proclaimed the constitution of Feb. 26, 1821. Soon afterward he returned

to Portugal, having appointed his son, Prince Pedro, regent of Brazil. A revolutionary movement took place in April, 1821. Brazil was proclaimed an independent empire, Oct. 12, 1822, and Dom Pedro crowned emperor Dec. 1. A constitution was adopted early in 1824; and the independence of the empire was acknowledged by the government of Lisbon, Sept. 7, 1825. In 1826 Dom Pedro became by the death of his father king of Portugal, but resigned that crown to his infant daughter Dona Maria da Gloria. In the same year the Brazilian government declared war against the Argentine Republic, which was seeking to convert Uruguay into an Argentine province; but peace was restored through the mediation of Great Britain, and Montevideo declared an independent republic. Meanwhile disputes had arisen between the emperor and the chamber of deputies, and only ceased with the abdication of the former, April 7, 1831, in favor of his son Pedro II., then in his sixth year. (See PEDRO I.) The country was governed by a regency till 1841, when the emperor was declared to have attained his majority, and crowned July 18. A law for the abolition of the slave trade was promulgated in 1831, and another in 1850 for the final abolition of slave traffic. Several political uprisings occurred in the empire from 1841 to 1849, chiefly in Minas Geraes and Pernambuco, directed against the provincial governments, or against the measures or ministers of the central government; but none attained the proportions of a civil war. An alliance was formed by Brazil, Uruguay, and the forces of Entre Rios, against Rosas, the Argentine dictator, with whose fall (at Monte Caseros) and flight to England, hostilities were terminated in February, 1852. In 1865 war was declared against Paraguay, and an offensive alliance was formed between Brazil, Uruguay, and the Argentine Republic, May 1, with the express stipulation that "none of the high contracting powers should lay down arms until the present government of Paraguay should be overthrown." For the motives, progress, and termination of this long and disastrous war, which ended in the defeat and death of the dictator Lopez, March 1, 1870, see ARGENTINE REPUBLIC, and PARAGUAY. Toward the close of the year 1871 a controversy arose between the governments of Buenos Ayres and Rio de Janeiro, which threatened for a time to disturb the friendly relations existing between Brazil and the Argentine Republic. The latter protested against certain treaties concerning boundaries and a war indemnity ratified separately with Paraguay by Brazil, without the concurrence of the two other allied powers, and in violation of certain articles of the treaty of alliance of May 1, 1865; but the negotiations between the two countries came to a favorable termination in October, 1872, it being agreed that the Argentine government should also arrange boundary questions by separate negotiation,

as Brazil had done. In 1848 yellow fever broke out in the province of Bahia, and spread rapidly through all the maritime provinces, causing frightful mortality. In 1855 an epidemic of cholera morbus visited Pará, and afterward the other provinces, carrying desolation through all parts of the empire, and especially Alagoas. In 1872 an unknown distemper manifested itself in three towns, and carried off 13,000 out of 18,000 inhabitants.—See "The Naturalist on the River Amazons," by Henry Walter Bates (2d ed., 8vo, London, 1864); "A Narrative of Travels on the Amazon and Negro," by Alfred R. Wallace (8vo, London, 1853); "A Journey in Brazil," by Prof. and Mrs. Louis Agassiz (8vo, Boston, 1870); "Geology and Physical Geography of Brazil," by Prof. Hartt (8vo, Boston, 1870).

BRAZIL NUT, the fruit of the *Bertholletia excelsa*, a large tree of the order *myrtacea*, found chiefly on the Orinoco. The nuts are of the form of triangular prisms, with very hard shells; they are often called cream nuts, and contain a rich, oily, solid meat. They are arranged in

Brazil Nut, showing Fruit cut open, disclosing the arrangement of Nuts.

four cells, each of which contains six or eight nuts, and all are included in a spherical case, half as large as a man's head. The Portuguese formerly carried on an extensive trade in these nuts. They are now chiefly exported from Pará, and continue to form an article of great commercial importance. When fresh, they are highly esteemed for their rich flavor; but they become rancid in a short time from the great quantity of oil they contain. This has been largely extracted for use in lamps.

BRAZIL WOOD, the name given to several varieties of red dyewood, brought from South America, Central America, and the West Indies. The genuine Brazil wood, sometimes called Pernambuco wood, is brought from the province of this name in Brazil. The tree is known as the *caesalpinia echinata*. Other varieties are the *braziletto* (the most inferior kind of Brazil wood), from the West Indies, the product of the *C. Brasiliensis*; the *sapan*,

or sampfen wood, of the *C. sapan*; and the Nicaragua or peach wood, also from a species of *cassalpinia*. It is said that the name was applied to the wood (of which there are species

Brazil Wood.—Leaves, Flower, and Fruit.

in the East Indies) long before the discovery of America, and that the great territory in South America was named Brazil in consequence of the abundance of the *cassalpinia* trees. So valuable were these considered that the wood was monopolized by the crown, and called *pão da rainha*, queen's wood. The tree grows to a large size, is crooked and knotty, and bears fragrant red flowers and small leaves. The wood is heavy and hard, takes a fine polish, and sinks in water. When first cut it is pale, but the red color deepens on exposure. The heaviest qualities are preferred. By boiling Brazil wood, reduced to powder, in water, the wood becomes black, while the water receives the red coloring principle, which is a crystallizable substance, named braziline. Long-continued boiling extracts it all; but a deeper red is imparted to alcohol or ammonia. The dye is improved by standing a few weeks, even if it ferments. At the best, however, it is not permanent; the colors are fixed only by a preparation of the articles to be dyed, which consists in impregnating them with suitable mordants, as alum and tartrate of potash. Acids and alkalis affect differently the shades of color of the dye; the former making it more yellow and permanent, and the latter deepening the hue to purple and violet shades. Brazil wood has been somewhat superseded by a dyewood of superior quality called camwood, supposed to be the product of the *baphia nitida*, which grows in Africa, and is obtained at Sierra Leone. It was formerly supposed that there were some medicinal properties in Brazil wood; it was observed to have a sweet taste, and to stain the saliva red, and it was made an ingredient in some prescriptions. It is now used in pharmacy only to color tinctures. Red ink is prepared from it by boiling the wood in water, and adding a little gum and alum; it is also used to make a

lake-red paint. Paper saturated with it is used in chemical analyses as a test for sulphurous acid, by which it is bleached; also for fluorine, which turns it yellow.

BRAZING, the uniting of two pieces of metal, as of brass or copper, or one piece of each, by hard solder. Hard solder is distinguished from soft by being made of metals that require a higher temperature to melt them; but all solders should melt more easily than the metals they unite; and to give the maximum of strength, they should have about the same hardness and malleability as these metals. For brass, copper, iron, German silver, &c., the solder used is an alloy of zinc and copper in equal parts, or for a harder mixture, two parts of zinc to three of copper. The two surfaces to be united are made perfectly clean and bright, then brought together and secured with wire or otherwise in their place, and covered around their edges with the granulated solder, mixed with pounded borax and wet with water. The parts are then heated; the borax melts, and runs over the bright surfaces, protecting them from oxidation; and as the heat increases it fluxes the solder, and this suddenly flushes, or runs through the joints, uniting with the two surfaces, and making with them one piece, as the parts cool and the solder sets. The pieces are then dressed with the file. It is sometimes convenient to cover the joints and the solder with a clay lute before heating; this is done in soldering iron, to prevent a scale of iron forming on the surface. The borax may be first melted and run into glass of borax, or allowed to froth up upon the joints.

BRAZORIA, a S. E. county of Texas, bordering on the gulf of Mexico; area, 1,260 sq. m.; pop. in 1870, 7,527, of whom 5,736 were colored. It is watered by the Brazos and San Bernard rivers, which are navigable, and by numerous smaller streams which flow into the gulf. The Houston Tap and Brazoria railroad terminates at Columbia in this county. The manufacture of extract of beef is extensively carried on. The surface is level, one half covered with valuable oak forests, and the rest prairie. The soil is red, deep, and very productive. The chief productions in 1870 were 207,881 bushels of corn, 2,988 bales of cotton, 4,740 lbs. of wool, 1,423 hhd. of sugar, and 92,450 gallons of molasses. There were 2,775 horses, 1,776 mules and asses, 2,207 milch cows, 42,770 other cattle, 1,856 sheep, and 7,487 swine. Capital, Brazoria, on the Brazos, 48 m. S. of Houston.

BRAZOS, a river which rises in the N. W. part of Texas, in Bexar district, flows first E., then S. S. E. across the state, and falls into the gulf of Mexico, in Brazoria county, about 40 m. S. W. of Galveston. The distance from its source to its mouth is nearly 500 m., which is increased by the bends of the river to about 900 m. During the rainy season, from February to May, it is navigable by steamboats about 300 m. to Washington, and at all times 40 m. to Columbia.

BRAZOS, a S. E. central county of Texas, bounded E. by the Navasoto river and W. by the Brazos, which unite at its S. extremity; area, 578 sq. m.; pop. in 1870, 9,205, of whom 3,759 were colored. It has an undulating surface, about one half of which is covered with oak and other trees. Much of the soil is rich loam. There are mineral springs of sulphur and magnesia. The Houston and Texas railroad traverses the county. The chief productions in 1870 were 205,864 bushels of corn, 38,597 of sweet potatoes, 6,927 bales of cotton, 18,001 lbs. of wool, and 36,639 of butter. There were 2,172 horses, 2,852 milch cows, 14,145 other cattle, 8,565 sheep, and 14,420 swine. Capital, Bryan.

BRAZOS DE SANTIAGO, a village and port of entry of Cameron county, Texas, on the gulf of Mexico, near Point Isabel, 35 m. E. N. E. of Brownsville. For the year ending June 30, 1871, the imports from foreign countries amounted to \$1,517,409; domestic exports, \$695,889; foreign exports, \$1,740,607. The foreign entrances were 33 vessels, of 8,525 tons, and the clearances 42 vessels, of 11,739 tons; in the coasting trade, the entrances were 76 vessels, of 33,458 tons, and the clearances were 71 vessels, of 31,915 tons.

BRAZZA, the largest and most productive island in the Dalmatian archipelago, belonging to Austria; area, 153 sq. m.; pop. about 16,000. It is mountainous, San Vito, the highest summit, being about 2,500 ft. It has good harbors, and trades in wine. Capital, San Pietro.

BREAD. See ALIMENT.

BREADFRUIT, the product of the breadfruit tree (*artocarpus incisa*), which belongs, like the yack (*A. integrifolia*), to the order *urticaceae*, distinguished in the sub-order to which

Breadfruit Tree.

artocarpus belongs by flowers combined in fleshy heads, stems with milky juice, which is often acrid, sometimes nutritious. The breadfruit is a native of the Pacific islands, where it

grows to the height of 40 feet or more, and from the size of its deeply incised leaves, more than a foot long and 10 inches wide, forms a very ornamental tree. The wood is much used,

Breadfruit—Leaves, Flower, and Fruit.

and the juice furnishes a sticky birdlime, but the fruit is the most valuable part. The flowers are unisexual, and the cluster of female flowers becomes a green globular fruit, half a foot or more in diameter. The seeds are roasted and much resemble chestnuts; but the varieties most prized do not bear seed; the ovaries become thickened, and when nearly ripe the receptacle is gathered and baked, by preference in ovens in the ground. The crust is removed to the depth of half an inch, and the farinaceous pulp eaten fresh, when it much resembles bread made with eggs, and of close texture; or it is mashed and packed in bundles which are buried in the earth for future consumption. A slight fermentation takes place and then ceases, and the pasty mass will keep several months. If suffered to remain on the tree until fully ripe, the fruit becomes sweet and resembles clammy cake rather than bread, with an unpleasant odor. Where seeds are not produced the tree is propagated by suckers or cuttings. Mixed with cocoanut milk, the pulp makes an excellent pudding. The fibre of the bark is used for *tapa*, or bark cloth, being strong as in most of the nettle family.—The yack differs from the breadfruit in having a smaller, entire, glabrous leaf, and attains a greater height, while the branches are not so spreading. The fruit is longer than the breadfruit and two or three times as large, and springs from the trunk of the tree, as the branches would be unable to bear so great weight. The seeds are enclosed in a sac of juicy yellow pulp, which has a strong stench of decomposing animal matter. When the repugnance to the smell is overcome, the pulp becomes a favorite edible. The yack is much cultivated in India.

BREAKWATER, an obstruction of any kind raised to oppose the action of the waves, and

make safe harbors and roadsteads. The outer mole of the harbor of Civita Vecchia was built by the emperor Trajan for this purpose; and the piers of ancient Piræus and of Rhodes are of the same class of structures. Josephus says that Herod, in order to form a port between Dora and Joppa, ordered mighty stones to be cast into the sea in 20 fathoms water, to prepare a foundation; the greater number of them being 50 ft. in length, 9 ft. deep, and 10 ft. wide, and some even larger. In the use of such immense blocks of stone, the true principles of constructing a permanent barrier to the waves appear to have been better understood than they were 17 centuries afterward. In modern times, the great breakwaters are those of Cherbourg in France, of Plymouth in England, and of Delaware bay in this country. From the experience acquired by their construction and history, principles before little understood have been established, upon which such works must be built to withstand the enormous forces opposed to their permanency. These were so little known in the last century, that one of the commissioners appointed by direction of Louis XVI. to report upon the best locality for establishing, opposite the English coast, a port and naval arsenal, recommended the construction of a dike of 2,000 toises in length, in water 70 ft. deep, in front of the harbor of Cherbourg, by sinking a vast number of ships filled with masonry as a nucleus, and covering these with heavy stones to within 18 ft. of the surface. And when at last four of the ablest naval officers and engineers of France were appointed to execute the work, which was regarded as one of the most stupendous operations, certainly the greatest piece of hydraulic architecture, ever undertaken by man, the plan they adopted was one which proved impracticable after having been prosecuted from the year 1784 to 1789, at enormous expense. This plan was the construction of huge truncated cones of timber, which, of the reduced size at which they were actually built, measured 36 ft. in height, with a circumference of 472 ft. at base, and 839 ft. at top, the angle of the slope being 60° . This was strengthened by an interior concentric cone, 5 ft. 10 in. within the outer one. The frame of each was made of 80 large upright timbers 24 ft. long and 1 ft. square. On these were erected 80 more of 14 ft. in length, making 320 of these uprights for the two exterior and two interior portions. The structure was then planked, hooped, and firmly bolted together. The first cone was built and floated at Havre, then taken to pieces, transported to Cherbourg, and floated off and sunk on June 6, 1784; the second on July 7, in the presence of 10,000 spectators; but before the cavity of this one could be filled with stones, its upper part was demolished in August by a storm of five days' continuance, and the stones it contained were spread over the bottom, interfering with the placing of the next cone. The original plan was to set 90 of these cones,

of 150 ft. diameter at base, 60 at top, and 65 ft. in height, in succession, and fill them with loose stones or masonry, and the spaces between them with a network of iron chains, to break the force of the waves. The number was afterward reduced to 64. After the second cone went to pieces, the government directed that the remainder should be set 192 ft. apart. This distance, by a new order, was increased to 1,280 ft., the spaces to be filled in with loose stones. At last, when 18 cones had been sunk at enormous expense, and with serious damage to many of them, the plan was abandoned, and the tops of those left standing were cut off down to low-water mark in 1789, and the system of construction by sinking rocks was recognized as the only process sure to succeed. The filling in of stone was continued till, at the end of the year 1790, the quantity sunk was estimated at 5,300,000 tons; and the total expenditure, by the estimate presented to the legislative assembly in 1792, was about 81,000,000 francs, or \$5,800,000. The commission appointed in 1792 by the departments of war, marine, and the interior, reported, after careful examination of the dike and of the partial protection it already afforded at different stages of the tide, that its stability could not be depended upon except by the use of larger blocks of stone as a facing than had before been employed, these stones to be at least of 15 to 20 ft. cube; and they recommended that the dike be raised 31 ft. above the level of the lowest tide, which would make it about 9 ft. above that of the highest tides. But the revolution succeeding, further work was interrupted. In 1802, by advice of a new commission appointed two years previously by a new government, it was determined to raise the central portion of the breakwater to the height before recommended, for 195 metres (640 ft.) in length, and to give it a breadth at top of 19.5 metres, in order to construct upon it a battery of 20 pieces of the heaviest artillery; and it was proposed to finally complete the two extremities in the same manner. At that time the old work, which had originally been raised to low-water mark, was reduced by the action of the sea to 15 or 18 ft. below it, and the profile imparted to it was regarded as that of greatest stability with least expenditure of material. The interior slope was one of equal height and base, 12.5 metres. The slope exposed to the sea had at bottom a height of 6.3 metres to a base of 9, succeeded by one of 6.2 to a base of 47.5; its original form was a uniform slope of 1 in height to 3 of base. The sea washing over the top tended to move the stones from the outside to the inside; and it was essential to oppose this action by raising the top above the surface of the water. In 1803 the central portion was completed to low-water mark, and a superstructure or parapet, of blocks of 60 to 80 cubic feet each, was raised along the south or inner side to the height of the highest tides, along which the smaller stones used in the construction, pressed upward

by the great waves in the winter storms, collected and formed a solid and compact surface, at a new slope, of which the base was about quadruple the vertical height. It was observed that the lateral movement of the small stones by the storms, driving obliquely along the outer face of the dike, caused them to collect at each extremity in a conical mound of the precise configuration traced for the proposed terminal batteries; but to prevent their extending into and obstructing the passes, it was found indispensable to face the whole exterior with blocks large enough to resist these oblique impulses. In May, 1805, the battery on the central portion was armed with 20 pieces of heavy ordnance. In February and May, 1807, occurred two great storms, the effects of which upon this portion, as also of the unprecedentedly severe storm of Feb. 12, 1808, are described in the "Memoir upon the Dike of Cherbourg, compared with the Jetty or Breakwater at Plymouth," by the baron Cachin, inspector general of roads and bridges. In the last named storm the battery was submerged, the parapet was upset, and the barracks and garrison, with 60 men, were swept away. The large blocks of stone with which the dike was faced were by this storm arranged in new positions, and so closely stowed that they appeared as if placed by the hand of man in positions of the most perfect stability. As thus arranged, the outer side presents four slopes. At the upper part, reached only by the tops of the waves, the height is to the base as 100 to 185. Beneath this is the space between the high and low-water marks, which is exposed at all times of tide to the most violent action of the sea; its slope is the most inclined, the height being to the base as 100 to 540. Below the lowest spring tides is a space but little exposed to the action of the waves; the height of this slope to its base is as 100 to 302. The lowest part, which is always submerged, has a height of 100 to a base of 125. The slope on the inner side is of 45° . From the experience of these two breakwaters, incomparably the greatest of their sort which have ever been undertaken, M. Cachin concludes with the observation, that if man be strong enough to heap together rocks in the midst of the ocean, the action of the sea alone can dispose them in the manner most likely to insure their proper stability. This, it may be added, will necessarily vary in form with the specific gravity and

FIG. 1.—Section of Cherbourg Breakwater.

size of the stones used. In 1830 it was decided to raise the dike by building up a wall of rubble masonry faced with granite to the height of 6 ft. above highest water. This is protected

by a foreshore of great blocks of stone on the outer side, which extend in a slope of 120 ft. to the depth of 21 ft. below low-water mark. This nearly vertical wall (the slope of its sides being $\frac{1}{2}$ to 1) is 36 ft. 3 in. wide at base, and 29 ft. 3 in. wide at top. A parapet is raised to the height of 6 ft. upon its outer edge, which is 8 ft. 8 in. thick; at top 8 ft. 6 in. wide. The altitude of the breakwater is given by the United States commission of engineers and naval officers, who examined it in 1829, at 72 $\frac{2}{3}$ ft., the base of its sea slope being 228 $\frac{5}{8}$ ft.; and they state that similar proportions were adopted at the Plymouth breakwater, the altitude of which is 57 ft., and base 180 ft. The inner slope of this, however, was built at an angle of 32° , although that of Cherbourg had stood perfectly well at 45° . The adoption of the general plan of this work by the English and American engineers sufficiently proves the correctness of its principles, though by some English authorities the work is alluded to as a failure.—The breakwater at Plymouth, England, to protect the inner harbor from the heavy sea that is driven in by southerly storms, was commenced in 1812. Its dimensions are only about one fourth of those of

FIG. 2.—Section of Plymouth Breakwater.

the breakwater at Cherbourg, its total length being 1,700 yards, made up of a central portion of 1,000 yards, and a wing bending in from each end, at an angle of 120° , of 350 yards. Its profile is 993 sq. ft. It was designed to have a base of 210 ft., breadth at top 30 ft., and height in the middle 40 ft. Its actual height exceeds this, but it is only about 3 ft. above the highest tides. It is built of large blocks of limestone, some exceeding five tons in weight, brought in vessels from the quarries at Catwater, about $2\frac{1}{2}$ m. up the harbor. The convenience of position of these quarries for loading the vessels, the facilities of quarrying the stone, and the judicious arrangements introduced, made the work of comparatively light expense. After some experience was had, the stone was quarried by contract at 2s. 5d (58 cents) per ton, and transported for 34 cents; and the total cost of the stone laid, including land purchases, salaries, buildings, &c., was estimated in 1816 at about 8s. 1 $\frac{1}{2}$ d. per ton. In 1841 it was calculated that 3,369,261 tons of stone had been laid, at a cost of nearly £1,500,000; and the work was considered as being essentially completed. The 15 vessels kept employed in transporting the stone were furnished with two railways laid along in the hold, upon which were run the loaded cars from the quarries, entering through two stern-ports. These could be tightly closed when the vessel was loaded. On each

side were arranged eight trucks of the extreme capacity of five tons each. In discharging, these were drawn out by a windlass on deck, and upset as they passed out of the ports, each one being drawn up on the deck and run forward to make room for those behind. At the quarries they left the deck, and the track on which they descended over the stern being raised up, the loaded cars were run under it, into the hold. The usual cargo of 45 to 65 tons could thus be discharged in less than an hour. On Jan. 19, 1817, the work was tried by one of the most severe storms ever known. The breakwater, though in an unfinished condition, caused perfect protection to the inner harbor, where without it the damage would have been immense. Previous gales had had no effect upon it; but this caused the upper stratum of the finished part, 200 yards in length and 30 in breadth, to be stripped, and the huge stones of two to five tons weight to be carried over from the outside, and deposited upon the northern side of the breakwater. The quantity thus removed was estimated at 8,000 tons. Since that time the outer slope has been "cased with regular courses of masonry, dowelled, joggled, dovetailed, and cramped together; the diving-bell being brought into requisition for placing the lower courses, which were of granite, and were laid horizontally on their natural beds, and dovetailed, lewisied, and bolted together." This work was reported by Mr. Stuart, the superintendent of the breakwater, to have been done on a slope of 5 to 1, as the sea had left it. The foot of the outer slope has also been extended further out with loose stones, to give protection to the courses of masonry. The additional cost since 1841 for this and similar repairs has been about £200,000, making a total expense of £1,700,000.—The new breakwater at Dover, in process of slow construction, is formed by an outer and inner wall of ashlar masonry, with a course of granite on the face, and blocks of concrete made with Portland cement and shingle in the core of the work to the level of high water, above which it is filled

FIG. 3.—Section of Dover Breakwater.

with liquid concrete. The masonry commences from the chalk bottom of the bay, the blocks being placed by means of diving apparatus. Both the inner and outer walls deviate from a perpendicular about three inches to the foot, in steps. A parapet 15 ft. above the level of high water surmounts the work on the sea side. All the operations are carried on from timber staging. The water at Dover is very deep, 42 ft. at low tide, and the construction of the breakwater is upon the principle that the motion imparted by waves to water much

below the surface is vertical, and that a vertical wall is best calculated to resist their action. There is a difference of opinion on the subject, and more time than has elapsed since such structures have been commenced will be required to allow a definite conclusion to be reached.—The construction of an important breakwater was commenced at Portland, on the southern coast of England, in 1849. On July 25 Prince Albert laid the foundation stone, and ten years later the works were so far advanced as to afford safe anchorage to vessels. The breakwater commences with a pier which starts from the island of Portland, near the point where it is connected with the mainland. The pier runs due E. for about 1,900 ft., at which point there is an opening 400 ft. wide, with a minimum depth of 45 ft., to admit vessels. On the other side of this opening the outer mole of the breakwater commences, and, after proceeding a short distance in the same direction as the pier, turns, and extends in a N. E. direction for a distance of 6,000 ft. The pier, or inner mole, consists of a rubble mound composed of stones of all sizes, from masses of eight tons weight down to small chippings. After the mound had been well consolidated a trench was excavated in it down to the level of low spring tides and a wall of masonry erected. The face course of this wall is formed of large squared blocks, the body consisting of heavy rubble work set in water cement. The face courses, up to 6 ft. above high-water level, are of hewn granite, and the rest of the face is of the best stone from the neighboring quarries. The outer mole, or breakwater proper, is a rubble bank with a width at the base of 300 ft., at low-water level of from 90 to 100 ft., and at the top of 60 ft. The slopes on the sea face, from the bottom to a height of 12 ft., are 6 to 1; on the harbor face they are $1\frac{1}{2}$ to 1. The sheltered area is about 2,100 acres up to low water line. Connected with the works are two forts, an inner one on the end of the pier, and another at the further end of the outer mole. The inner fort is 100 ft. in diameter, mounts 8 guns, and stands in $9\frac{1}{2}$ fathoms of water. The outer fort has a rubble base 45 ft. high, and containing 140,000 tons of stone. Its diameter is 200 ft., and it stands in 10 fathoms of water. The completion of the work was celebrated with great pomp, Aug. 10, 1872, when the prince of Wales laid the top stone and declared the work finished. The execution of this magnificent work is interesting as affording an example of the economical use of the force of gravity alone as a motive power in moving loads to and from a given point. The quarries from which the stone is obtained are about 380 ft. above the sea level. Three inclined planes, each having two tracks, extended down to the breakwater. A wire rope passing over a drum connected two trains of trucks, one train descending with a load while the other ascended empty. A temporary staging was

constructed along the line of the breakwater on which the trucks were propelled, and from which their contents were dumped into the water. The quantity of stone deposited per day varied from 2,000 to 3,000 tons, the total quantity used in the work being about 6,000,000 tons. It was quarried and landed mostly by convict labor, from 600 to 1,000 prisoners having been employed. About 100 men were engaged in the actual work of construction. The cost of this extensive work has been only about £1,013,000, for which the British nation possesses one of the most magnificent harbors in the world.—In 1828 a commission consisting of Commodore Rogers of the navy, Brig. Gen. Barnard of the engineer corps, and William Strickland, architect and engineer, was appointed by the United States congress to ascertain the most eligible site and to prepare plans and estimates for a harbor near the mouth of Delaware bay. In their report, made Feb. 2, 1829, they selected Cape Henlopen as the site of a breakwater. They said: "The objects to be gained by an artificial harbor in this roadstead are to shelter vessels from the action of the waves caused by winds blowing from east to northwest round by the north, and also to protect them from injuries arising from floating ice descending from the northwest." They proposed two works, a breakwater proper, to secure the first object, and an ice-breaker, as an auxiliary to the breakwater, but chiefly to protect vessels against the ice. The breakwater was designed with a length of 1,200 yards, and on a course N. N. W. drawn from a pitch of the cape. The ice-breaker was designed with a length of 500 yards, on a course W. by S. $\frac{1}{4}$ S., and so placed that the line of the breakwater would meet its S. W. extremity if extended, leaving an opening between the breakwater and cape of 500 yards, and between the breakwater and ice-breaker an opening of 350 yards, with a depth of water of 24 ft. The area protected against all the most dangerous winds, with a depth of 3 to 6 fathoms, is estimated at 360 acres.

FIG. 4.—Section of Delaware Breakwater.

The work was commenced in 1829, under direction of Mr. Strickland, and in 1834 it was so far advanced that vessels found protection behind it. Blocks of rubble from the nearest quarries were thrown in to form their own slopes for a foundation. The outer covering to within 6 ft. of low-water mark was of blocks from 2 to 3 tons weight; from this to low-water mark they were of 3 tons; thence to high-water mark, 3 to 4 tons; and above this, 4 to 5 tons, to a height of 4 ft. 3 in. above highest water. The ordinary rise of tide is nearly 5 ft., equinoctial tides 7 ft., and extreme tides 10 ft. As

the breakwater was built, its exterior slope for the first 16 ft. from bottom was at an angle of 45°, thence to summit 28°, or 3 to 1. The inner slope was 45°. The surfaces of both slopes to the level of low water were paved with rough blocks set at right angles to the slope, and well wedged together, thus presenting as little surface as practicable to the action of the waves. The stone used in this work was obtained from a variety of sources, some trap rock from the Palisades on the Hudson river, greenstone from the northern part of Delaware, and gneiss from different quarries in Delaware. These rocks, though averaging a weight of 175 lbs. to the cubic foot, and employed of the dimensions named, were insufficient to withstand the action of the sea in the course of the construction of the moles. During the winter season, those upon the surface of the work were more or less displaced, and a large piece of 7 tons weight was moved in one storm 18 ft. to the inner slope of the ice-breaker, down which it was lost. At the same time about 200 tons of other heavy stone, that had been thoroughly wedged and compacted together, was torn up and swept over to the inner side. In 1839, according to the report of Major Bache in 1843, the breakwater was in course of construction for 862 yards, and the ice-breaker for 467 yards. Gen. (then Major) J. G. Barnard, in a report of the works made by him in 1853, says: "The last stone was deposited on the work under former appropriations in the year 1839; and since that date a work costing already nearly two millions of dollars, a work in every sense national, has remained in its half finished condition." As long ago as 1843 various plans were proposed for completing the work and rendering the harbor more commodious. Major Bache, in the report before referred to, says: "In order to remedy the defects of the harbor which are caused by the rolling of the sea entering between the works, three modes have been suggested: 1, to cover the gap by extending the ice-breaker; 2, to close the gap by extending the breakwater proper; and 3, to cover the gap by a detached work." He estimates the cost of each of the plans to be as follows: "1, for closing the gap by extending the breakwater, \$551,635; 2, for covering the gap by extending the ice-breaker, \$815,341; 3, for covering the gap by a detached work, \$959,664. To these estimates must be added severally the sum of \$108,921 for raising the existing works to their proper level, and for filling holes in the bottom at their ends." The report of Lieut. Col. J. D. Kurtz, of the engineers, for the year ending June 30, 1870, contains the following: "From July 1, 1869, to the completion of these works in conformity with the present design, Nov. 4, 1869, the work was carried on in furnishing stone by contract as heretofore, the United States performing the labor of placing the large stone in position by days' work. During the fiscal year 10,698 tons of large stone for the

superstructure of these works were received and placed in position, completing 120 running feet of the breakwater and 175 feet of the ice-breaker. In addition, 122 tons of old superstructure have been reset and 2,198 perches of small stone deposited in holes at the extremities of the works and on the sea side of the breakwater opposite the lighthouse. The length of the breakwater on the top is 2,558 ft.; about low-water line the length is 2,603 ft.; length at base, 2,763 ft. The length of the ice-breaker as completed on the top is 1,353 ft.; about low-water line, 1,389 ft.; length of base, 1,601 ft." Col. Kurtz in his report for 1871 says: "The completion of this harbor according to the original project was reported in last year's annual report. This project was devised more than 40 years ago. It is the case here, as in many other government works, that the growth of the country has far exceeded the provision made for its probable wants. Last year's report shows that 15,000 vessels were recorded as visiting this harbor. Adding those entering and leaving without being noted, 20,000 or 25,000 may be taken as the number that used the harbor during the year. Its present capacity is determined by the space that is sheltered by the breakwater proper. This is a straight line nearly half a mile long, and may be taken as the diameter of a half circle behind it, the area of which will represent approximately the sheltered harbor. Northeastwardly of the breakwater is the ice-breaker structure, a quarter of a mile in length, but separated by a gap of nearly equal extent, through which the sea rolls in northwestwardly weather without hindrance. If this were excluded, the sheltered area would be increased three or four fold." Col. Kurtz then presents the plans of Major Bache enumerated above, but is obliged to greatly increase the estimates of cost, viz.: for the first plan, \$1,314,000; for the second, \$1,944,950; and for the third, \$2,278,000. The existing works have cost \$2,127,403. A special board of officers, composed of Gens. Woodruff, Wright, and Newton, and Cols. Kurtz and Craighill, appointed for the purpose of considering the question of further improvements to the breakwater, met in November, 1871, and again in the summer of 1872. At the latter meeting a report was agreed upon favoring the plan of connecting the two moles by extending the breakwater proper until it meets the ice breaker.—Breakwaters are now in course of construction on our northern lakes, which are made of a crib-work of strong timbers filled with stone, and are found to be very effective, and to possess the advantage of economy and facility of construction. It has been found by experience that the cribs will keep in position better if the bottom is formed of latticework, sufficiently open to allow the stones to sift through when the crib is stirred by the waves. The cribs are usually made from 30 to 40 ft. in width, from 60 to 80 ft. in length, and of a depth suited to

the depth of water. They are successively sunk and placed end to end and filled with stone until the work has attained the desired length. There being no tide in these lakes, the top of the crib need not be more than 8 or 10 ft. above the mean water level. Such breakwaters, more or less approaching completion, are in process of construction at Buffalo on Lake Erie, at Oswego on Lake Ontario, at Plattsburgh and Burlington on Lake Champlain, and at other places. Aside from not possessing sufficient strength, these structures would not be practicable on the seacoast on account of the destruction to which the timber would be exposed from attacks of marine worms; but in our fresh-water lakes this objection does not exist. Timber which is placed below the action of the air in fresh water has been found to resist decay for an indefinite time, for centuries at least. If from any cause, however, the framework of the cribs should become weakened, new cribs can be placed on the inner or outer line of the first row, or on both sides, and thus a permanent stone foundation of rubble for a stone breakwater of the ordinary description may be gradually constructed.—The experience acquired by all these breakwaters, and by the action of the waves upon coasts exposed to their greatest violence, establishes the principle that blocks of stone of large dimensions only can be depended upon to retain their places. Mr. James Walker, president of the British institution of civil engineers, advanced the opinion in 1841 that a partial vacuum is created by the action of the waves, and the atmospheric pressure being taken off for an instant, the mass of stone is the more readily influenced by the forces which at the same time solicit it. ("Civil Engineer and Architect's Journal," September, 1841.) If the whole atmospheric pressure were taken off the surface, it would be equivalent to the removal of a weight represented by a column of rock 11½ ft. deep, weighing 175 lbs. to the cubic foot. Under such circumstances, and exposed to the action of a wave 20 ft. high, which is capable of moving masses of rock 7½ ft. deep, stability would be insured only by the addition of this amount to the 11½ ft. But as it is not probable that a large proportion of the atmospheric pressure is ever thus removed, and as 22 ft. is regarded as the maximum height of waves, a depth of solid stone of 15 ft., used as a coping, would probably resist all action of the waves.—The construction and history of the principal breakwaters are fully treated in the great work of Sir John Rennie, president of the institution of civil engineers, upon British and foreign harbors (2 vols. fol., 1854).

BREAM (*pomotis vulgaris*, Cuv.), an acanthopterygian fish, of the family *percidæ*, of which several species are found in North America, and of which the above, called also sunfish, pond perch, and roach, is the most common. In this genus the borders of the preoperculum have a few denticulations; no teeth on the

palatine bones and tongue, but with minute teeth on the jaws, vomer, and pharyngeals; branchial rays 6; a membranous elongation at

American Bream (*Pomotis vulgaris*).

the angle of the operculum. This beautifully colored species is common in fresh ponds, and is an excellent edible fish; the length rarely exceeds 8 inches. The color above is greenish brown, with rusty blotches irregularly distributed, in some specimens arranged longitudinally; undulating deep blue lines longitudinally across the gill covers; opercular membrane black, with a bright scarlet blotch at its posterior portion; abdomen whitish or yellowish; dorsal, anal, and caudal fins dark brown; ventrals and pectorals yellowish. The body is compressed; the back curves very gradually as far as the posterior extremity of the dorsal fin, and then abruptly gives place to the fleshy portion of the tail; the eyes are large and circular; nostrils double, the anterior tubular; mouth small, teeth minute and sharp; the lateral line assumes the curve of the back; the scales of the body are large, and dentated at the base, small at the base of the fins; the pectorals are long, and the caudal emarginate. The bream builds a circular nest along the shore, by removing the weeds and excavating the sand to a depth of half a foot and an extent of two feet; sometimes 20 or 30 occur within the space of a few rods, and often in very shallow water; over the nest the fish hovers, protecting its eggs and young for weeks; it darts against other fishes which come near, and is so intent on its guard duty that a spectator can approach very near, and even handle it. This species is found from Ken-

European Bream (*Abramis brama*).

tucky to the Canadian lakes.—The name of bream is given in Great Britain to several marine species of the family *sparidae*, as to the

cantharus griseus, Cuv., and to two species of *pagellus*; also to some malacopterygians of the carp family, as the *abramis brama*, or carp bream. The last named, the best known European fish of this name, is from 2 to 2½ ft. long, proportionally very deep and thin; yellowish white in color, growing darker by age, with a flesh-colored tinge below. It is found generally on the continent and in Great Britain, in lakes and the deepest parts of still rivers, and affords excellent sport to anglers, but its flesh is coarse and insipid.

BREATH. See RESPIRATION.

BREATHITT, an E. county of Kentucky; area, 600 sq. m.; pop. in 1870, 5,672, of whom 181 were colored. It is diversified by hills and forests, and intersected by the north and middle forks of the Kentucky river. Iron and coal are found. The chief productions in 1870 were 166,729 bushels of Indian corn, 8,205 of oats, 4,066 of wheat, 112,224 of potatoes, and 11,658 lbs. of wool. There were 835 horses, 1,494 milch cows, 3,024 other cattle, 7,629 sheep, and 9,055 swine. Capital, Jackson.

BREBEUF, Jean de, a French Jesuit missionary in Canada, born at Bayeux, March 25, 1593, killed in the Huron country, March 16, 1649. He came to America with Champlain in 1626, and proceeded to the Huron country, but was soon recalled by the disasters of the colony, and in 1629 was carried to England as a prisoner. Returning in 1632, he again visited the Huron country, extending his labors to the Neutres on the Niagara. He appreciated the peculiar character of the Indian mind, and thoroughly acquired their language. His influence and success were accordingly great. In the war waged by the Iroquois against the Hurons, the town of St. Louis, where he labored, was taken in 1649, and the missionary and his associate Lalemant were captured and put to death at St. Ignatius with the most fearful tortures. His head is preserved in the base of a silver bust at the convent of the hospital nuns, Quebec. Of his writings we have a Huron translation of Ledesma's catechism, published in Champlain's *Voyages* (Paris, 1632, 1640; Quebec, 1870); the *Huron Relation* in the Jesuit *Relations* of 1635 and 1636, embracing a treatise on the Huron language, translated by Gallatin in the memoirs of the American antiquarian society; and some letters published by Carayon, Paris, 1870.

BRECCIA (Italian), a compound rock composed of angular fragments, which appear to have once existed in other formations. If the fragments, before being reunited, have been rolled into the forms of pebbles, the new rock is called conglomerate or puddingstone. These and breccias are of frequent occurrence among the stratified rocks. The Potomac marble, of which fine specimens are seen in the capitol at Washington, is a breccia of marble, sandstone, and other minerals found in the new red sandstone formation, where it crosses the Potomac. Its various components having different degrees

of hardness, it is a difficult rock to polish, which prevents its coming into general use, as its beauty would render desirable. When breccias are produced from rocks originally stratified in their layers, it is curious to observe how the lines of these layers are preserved in the broken fragments, and may be traced in the various directions in which they are thrown together. Breccias are also prepared artificially. (See CONCRETE.)

BRECHIN, a royal burgh and parish of Forfarshire, Scotland, on the S. Esk, 8 m. from its junction with the sea at Montrose, and 23 m. N. N. E. of Dundee; pop. in 1871, 7,983. It is the seat of a Scottish Episcopal bishop. The cathedral built in the 12th century is now the parish church. Near the church is an ancient round tower, 103 ft. in height, one of the only two in Scotland. Many of the inhabitants are employed in linen weaving.

BRECKENRIDGE, a N. W. county of Kentucky, bordering on Indiana, bounded N. W. by the Ohio river, and having Rough creek for its S. limit; area, 450 sq. m.; pop. in 1870, 13,440, of whom 1,682 were colored. The surface consists of undulating uplands. The soil has a basis of red clay and limestone, and is fertile and well watered. Sinking creek in this county plunges below the surface, and is lost for 5 or 6 m., when it emerges from the ground, and flows into the Ohio. Penitentiary cave, near this creek, is said to contain chambers of vast size. The Tar and Breckenridge White Sulphur Springs are in this county. The Breckenridge coal is found here. The chief productions in 1870 were 57,921 bushels of wheat, 526,080 of Indian corn, 129,703 of oats, 22,918 of potatoes, 3,476 tons of hay, 139,207 lbs. of butter, 30,081 of wool, and 3,338,471 of tobacco. There were 3,672 horses, 2,565 milch cows, 4,115 other cattle, 13,525 sheep, and 25,386 swine. Capital, Hardinsburg.

BRECKENRIDGE, John, D. D., a Presbyterian clergyman, born at Cabell's Dale, Ky., July 4, 1797, died there, Aug. 4, 1841. He graduated at Princeton college in 1818. While at college he joined the Presbyterian church, and though his father, United States attorney general under Jefferson, had designed him for the law, he preferred the ministry. In 1822 he was licensed by the presbytery of New Brunswick to preach, and shortly after served as chaplain to congress. Having been ordained to the ministry, he was installed pastor of a church in Lexington, Ky. After remaining in this charge four years, during which time he established a religious newspaper entitled "The Western Luminary," he was called to the second Presbyterian church in Baltimore, as colleague with the Rev. Dr. Glendy. Appointed in 1831 secretary and general agent of the Presbyterian board of education, he removed to Philadelphia, and occupied this post for six years, when he was elected by the general assembly professor in the Princeton theological seminary. During his connection with the seminary he engaged

in two public controversies, one written and the other oral, with the Rev. John Hughes of Philadelphia (afterward archbishop of New York), which were published in book form. He took an active part in the controversies which agitated the Presbyterian church, as a leader of the Old School party. All his sermons, speeches, and arguments were extempore, yet correct and logical. In 1838, upon the organization of the board of foreign missions, he was elected its secretary and general agent, and devoted his entire time and energy to the superintendence of its operations till 1840, when his health gave way. At the time of his death he was pastor elect of a Presbyterian church in New Orleans, and president elect of Oglethorpe university, Georgia.

BRECKENRIDGE, John Cabell, an American politician and soldier, born near Lexington, Ky., Jan. 21, 1821. He was educated at Centre college, Danville, studied law at the Transylvania institute, and settled at Lexington. At the breaking out of the war with Mexico he was elected major of the third regiment of Kentucky volunteers, but had little opportunity for active service. After the war he was elected to the house of representatives of Kentucky, and in 1851 was chosen to congress, and in 1853 was reelected after a violent and protracted contest. During the first session of the 33d congress, in the course of the discussion of the Kansas-Nebraska bill, he was involved in a personal altercation with Mr. F. B. Cutting, a member from New York, leading to the preliminaries for a duel, which, however, did not take place. Upon the accession of President Pierce he was offered the ministry to Spain, but declined it. In 1856 he was elected vice president, in conjunction with Buchanan as president. In 1860 the disunion delegates in the democratic national convention, having separated from the supporters of S. A. Douglas, nominated Mr. Breckenridge for president, and he received the electoral votes of all the southern states except Virginia, Kentucky, Tennessee, and Missouri. In the same year he was elected United States senator. After defending the southern confederacy in the senate, he went south, entered the army, and rose to the rank of major general. He was repulsed in an attack on Baton Rouge in August, 1862; commanded a corps under Bragg at Stone river at the end of 1862, and at Chickamauga in September, 1863; defeated Sigel at Newmarket in May, 1864; participated in Early's advance on Washington in July of that year, and shared in his defeat near Winchester in September. In January, 1865, he was appointed confederate secretary of war. After the surrender of Gen. Lee he went to Europe, whence he returned in 1868, and has since lived in Kentucky.

BRECKENRIDGE, Robert Jefferson, D. D., LL. D., uncle of the preceding, and brother of the Rev. John Breckenridge, an American divine, born at Cabell's Dale, Ky., March 8, 1800,

died at Danville, Ky., Dec. 27, 1871. He studied successively in Princeton, Yale, and Union colleges, and practised law in Kentucky for eight years from 1823, being several times a member of the state legislature. In 1829 he joined the Presbyterian church, and in 1832 was ordained pastor of the first Presbyterian church in Baltimore, in which position he remained 13 years. In 1845 he was elected president of Jefferson college, Pennsylvania, where he remained two years, at the same time being pastor of the church in a neighboring village; after which he removed to Kentucky, and became pastor of the first Presbyterian church in Lexington, and superintendent of public instruction for the state. In 1853 he was elected professor of theology in the seminary at Danville, Ky. During the controversies which led to the disruption of the Presbyterian church, he became the acknowledged leader of the Old School. It was chiefly through his agency that the managers of the American Bible society, after voting to adopt the revised edition of the Bible as their standard, subsequently receded from that action. He was the principal author of the common school system of Kentucky. In the anti-slavery discussion he took a decided course in opposition to extreme opinions on either side, and advocated the passage of a law for manumitting the slaves in Kentucky. When the civil war broke out he took a firm stand in favor of the Union, but he wrote against Mr. Lincoln's emancipation proclamation. In 1864 he presided over the republican national convention which renominated Mr. Lincoln for the presidency. While in Baltimore he edited the "Religious and Literary Magazine," and at Danville the "Danville Review." He published two works of foreign travel (1 vol., 1839; 2 vols., 1845); "Papism in the United States" (1841); "Internal Evidences of Christianity" (1852); "The Knowledge of God objectively Considered" (1857); and "The Knowledge of God subjectively Considered" (1859).

BRECKNOCK, or **Brecon**, an inland county in the south of Wales, traversed by the Black mountains and other ranges, containing the Van or Beacon mountain, 2,862 ft. high, and noted for its magnificent scenery; area, 716 sq. m.; pop. in 1871, 59,905. The river Wye bounds it on the N. E. and N., the Usk flows through it, and near its centre is Brecknock Mere, or Llans-afeddar, one of the largest lakes in S. Wales. The soil on the mountains is poor, but the valleys yield grain, potatoes, and turnips in abundance, and these, together with timber, wool, cattle, and dairy produce, constitute the chief resources of the county. About half of the land is under cultivation. The mineral productions, embracing coal and iron, are inconsiderable. There are iron works in the E. part, but they draw both ore and fuel principally from other counties. The manufactures are coarse woollens and worsted stuffs.

BRECKNOCK, **Brecon**, or **Aber-Honday**, a parliamentary and municipal borough and market

town of Wales, capital of the county of its own name; pop. in 1871, 5,845. It is situated in a healthy and beautiful valley, at the confluence of the rivers Honddu or Hondey, Tarrell, and Usk, the first of which is crossed by three bridges, and the last by one. It has three long avenues intersected by a number of shorter ones, all well kept and paved, and most of them straight. The public walks are remarkably beautiful. The Brecknock and Abergavenny canal, 35 m. long, joins with the Monmouth canal, 18 m. long, which connects it with the Usk; and a railway with Merthyr Tydvil, 14 m. S. The town was once surrounded by walls, which were demolished by the inhabitants during the last civil war, in order to avoid a siege. Brecknock was founded about 1092, when a castle was built by Bernard Newmarch, a relative of William the Conqueror. Its ruins are included in the grounds of the Castle hotel.

BREDA, a strong town and fortress of the Netherlands, province of North Brabant, at the junction of the rivers Mark and Aa, 24 m. W. S. W. of Bois-le-Duc; pop. in 1868, 15,265. A canal connects the town with the Maas. Woollen goods, carpets, and tapestry are manufactured here; there are also tanneries and breweries. The town is noted for its military and naval academy. The principal Protestant church contains many interesting monuments and works of art. During the wars of the reformation, of the Spanish occupation of the Netherlands, and the later wars between the Dutch, Spaniards, and French, it was a constant object of contention. It was taken by surprise in 1581, and was recaptured by a skilful stratagem in 1590 by Maurice of Nassau. In 1624-'5 it endured a siege of ten months by Spinola, and again one of four by Henry of Orange, its resistance in neither instance being successful. During the French war of the revolution it was taken by Dumouriez in 1793, but liberated in consequence of his losing the battle of Neerwinden; in 1794 it was besieged by Pichegru, and held out until the whole of Holland surrendered; and lastly in 1813, when on the approach of the Russian vanguard the French garrison sallied against Benkendorff, the townspeople rose and shut the gates on the defenders, and finally surrendered it to the allies for Holland. The famous declaration of Breda, made by Charles II. to parliament previous to his restoration, May 1, 1660, promised a general amnesty, liberty of conscience, a settlement of forfeited estates, and liquidation of arrears to the army. The peace of Breda, between Holland, England, France, and Denmark, was concluded July 31, 1667.

BREDERODE, **Hendrik van**, count, a patriot of the Netherlands, a descendant of the old sovereign counts of Holland, born in Brussels in 1531, died at the castle of Hardenberg, in Germany, in 1568. He was one of the leaders in the rising against the Spanish domination in the Netherlands. In 1562 he made himself conspicuous by his wild demonstrations against

Cardinal Granvelle; and in 1565, at a banquet given to Egmont, he grossly insulted the archbishop of Cambray, who was one of the guests. Brederode, Charles de Mansfeld, and Louis of Nassau were the first three signers of the original protest ("the compromise of Breda"), made early in 1566, against the inquisition. He was chosen as bearer of the memorable petition addressed by the states general to the regent, Margaret of Parma, in which capacity he made his entry into Brussels April 3. On the 8th he gave a banquet, at which the healths of himself and of Egmont and the prince of Orange were drunk. Berlaymont, the state councillor, had told the duchess of Parma that the signers of the petition were a parcel of beggars. This was reported at the banquet, whereupon Brederode exclaimed, "They call us beggars! let us accept the name. We will contend with the inquisition, but remain loyal to the king, even if compelled to wear the beggar's sack!" He then hung a leathern wallet, the badge of a mendicant, around his neck, and gave the toast, *Vivent les gueux*—"Long live the beggars!" which became the war cry of the Dutch uprising. During the autumn and winter of 1566 Brederode excited disturbances near Valenciennes in order to make a diversion in favor of that city, which was then besieged. In January, 1567, he established his headquarters at Vianen, where he had seigniorial rights. He strengthened its fortifications, removed all statues and emblems from the Roman Catholic churches, and assembled turbulent bands, keeping the Spanish authorities in perpetual apprehension. Early in February he visited the prince of Orange at Breda, in order to inform him of the new petition which he had prepared for presentation to the duchess of Parma. The duchess declining to grant him letters of safe-conduct to Brussels, he forwarded the document to her from Antwerp. It claimed the exercise of the reformed religion as a right, and insisted upon the dismissal of the Spanish forces and the faithful fulfilment of the concessions of August, 1565. The regent ordering him to leave Antwerp, he accepted her threatening answer as a formal declaration of hostilities, and began to enlist troops in that city and its vicinity, apparently with a view of making an attempt upon the island of Walcheren. He anticipated the formal proclamation of the prince of Orange against these enlistments by removing the scene of his operations to Holland, saying that he took the field to relieve Valenciennes, and dictate peace in Brussels. But he remained at Vianen and Amsterdam after the disastrous expedition of Marnix de Tholouse to Middelburg, which he had planned, but in which he had not assisted; and in Amsterdam he disgusted even the reformers by spending his time in singing the beggars' songs, without showing any capacity for serious enterprises. At length, in March, 1567, the regent demanded that Brederode should be

expelled from Amsterdam; whereupon he bullied her secretary, and denounced the duchess as a tyrant. But early in April, after hearing of the success of the Spaniards, he begged Egmont to intercede for him with the regent; but as she would not accord him any terms, he set out for Emden in the night of April 25. He died before the lapse of a year, of disappointment and intemperance. His followers dispersed after his departure from the Netherlands, many of them being captured and put to death. His daughter recovered his estates after the restoration of peace; but as she left no issue, they passed into the hands of a junior branch of the family, which became extinct in 1679, when they passed to the counts van der Lippe, who in 1727 sold the principal domain of Vianen to the states general. Mr. Motley charges Brederode with having disgraced his party by his buffoonery, and with having done nothing for the cause of freedom. M. C. van Hall, however, had previously written in his defence, *Hendrik Graaf van Brederode verdedigd* (1845); and P. Scheltema published *Hendrik van Brederode te Amsterdam in 1567* (1847).

BREDOW, Gabriel Gottfried, a German historian, born in Berlin, Dec. 14, 1773, died in Breslau, Sept. 5, 1814. He was a graduate of Halle, forsook theology to devote himself to the study of the geography and astronomy of the ancients, on which he published several works, and was professor in different institutions, and finally in the university of Breslau. His historical works met with remarkable success, especially the *Merkwürdige Begebenheiten aus der allgemeinen Weltgeschichte*, and the *Umständliche Erzählung der merkwürdigsten Begebenheiten aus der allgemeinen Weltgeschichte*; the former passed, between 1804 and 1852, through 26 editions, and the latter through 13.

BREE. I. Mathieu Ignace van, a Belgian painter, born in Antwerp, Feb. 22, 1773, died there, Dec. 15, 1839. He was a pupil of Schaecken in Antwerp, and of Vincent in Paris, and became early distinguished by his rapid execution of large historical pictures. His most celebrated painting, representing the famine of Leyden in 1576, is in the town hall of that city. His "Johanna Sebus" was presented in 1858 to the Prussian town of Oleva, and his "Rubens" is in the possession of the grand duke of Saxe-Weimar. His portraits are also admired. He excelled as a lithographer and sculptor, and was director of the academy of fine arts at Antwerp. **II. Philippe Jacques van**, brother and pupil of the preceding, born in Antwerp in 1786, died there in 1840. He completed his studies in Paris and Rome, and produced many historical and other paintings, including "Oriental Travellers," "A Spanish Nun," "Atala," "Queen Blanche with her Child, the future St. Louis," "Maria de' Medici and Louis XIII. in the presence of Rubens," "Mary Stuart on the Eve of Execution," "Petrarch surprised by Laura," and "The Abdication of Charles

V." His "Interior of St. Peter's" was purchased by the Belgian government.

BREDE (Dutch, broad), a river of Cape Colony, S. Africa, which rises in a mountain basin, and breaking through the mountains, takes a S. E. course to the sea, at Port Beaufort. It is one of the deepest and largest rivers of the country, but navigation is impeded by a bar at its mouth.

BREGENZ (anc. *Brigantium*), a town of Austria, capital of Vorarlberg, situated at the E. end of the lake of Constance, near the mouth of the river Bregenz; pop. in 1870, 3,686. It is well built, and has considerable trade. Wooden houses ready made for the Alpine districts of Switzerland, and vine poles for the vineyards on the lake, are exported in large numbers. Not far from the town is the Bregenzer Klause, a pass formerly fortified. The Bregenzer Wald is a spur of the Allgau Alps. The lake of Bregenz is the name given to the S. E. portion of

Bregenz.

the lake of Constance. A treaty between Austria, Württemberg, and Bavaria against Prussia, in reference to the Hesse-Cassel imbroglio, was concluded here, Oct. 12, 1850. A conference for the regulation of the navigation of the lake of Constance was held here by the riparian powers in October, 1855.

BREGUET. I. Abraham Louis, a Swiss watchmaker, born at Neuchâtel, Jan. 10, 1747, died Sept. 17, 1823. He established a manufactory in Paris, and was appointed chronometer maker to the navy, member of the bureau of longitudes, and member of the institute. His pocket chronometers, marine timepieces, sympathetic pendulums, metallic thermometers, and mechanism of telegraphs, as established by Chappe, attest his skill. **II. Louis**, grandson of the preceding, born in Paris, Dec. 22, 1804. In 1826 he was placed at the head of the chronometer department of the navy founded by his grandfather. He soon turned his attention toward the application of the physical sciences, and especially to the electric telegraph. The timepieces constructed by him maintain the reputation gained by his father and grandfather.

BREHM, Alfred Edmund, a German naturalist and traveller, born at Renthendorf, Feb. 2, 1829. He studied under his father, Christian Ludwig Brehm, an eminent ornithologist (1787-1864). After making zoological collections during five years' travel in Egypt, Nubia, and eastern Soodan, he studied at Jena and Vienna, subsequently visited Spain, Norway, and Lapland, and in 1862 N. Abyssinia, in company with Duke Ernest of Saxe-Coburg-Gotha. He was director of the zoological gardens at Hamburg from 1863 to 1867, when he removed to Berlin, where he established the famous aquarium. He wrote *Das Leben der Vögel* (Glogau, 1860-'61; 2d ed., 1867; English translation, "Bird Life," by H. M. Labouchere and W. Jesse, 4 parts, London, 1872); *Illustrirtes Thierleben* (6 vols., Hildburghausen, 1863-'9); and *Gefangene Vögel* (2 vols., Leipzig, 1870 *et seq.*). Among his books of travel are *Reiseskizzen aus Nordostafrika* (3 vols., Jena, 1855-'63), and *Ergebnisse einer Reise nach Habesch* (Hamburg, 1863).

BREHON LAWS, the ancient body of laws under which the Celtic Irish lived for many ages, to which they clung with reverence until the beginning of the 17th century in at least one province of Ireland, Ulster, and which very gradually gave place to English laws founded on the feudal system, in proportion as British arms and policy completed the conquest of the island. The Brehon laws were not properly a code, but were simply the whole body of ancient legal maxims and usages as administered by the brehons, who were the judges of the land. Brehon (*breithamh*) signified a judge or professor of law; and the root is the Irish word *breith*, judgment or right. The brehons formed a kind of college or faculty; and each great clan had its own brehons, whose office was hereditary, not in the feudal sense, by descent from eldest son to eldest son, but in the Gaelic sense, in which the chiefs of clans and high-kings, or *ardrighs* of Ireland, came to their own offices and dignities. Much light has been thrown upon the whole subject within a few years past by the labors of a government commission. As early as 1783, Edmund Burke suggested the propriety of collecting and publishing in English or Latin these remnants of a former civilization, but it was not till 1852 that the English government consented to lend its aid to the work. In that year, at the special instance of Drs. Todd and Graves, both Protestant clergymen, a commission was issued appointing them and several other scholars "to direct, superintend, and carry into effect the transcription and translation of the ancient laws of Ireland, and the preparation of the same for publication," with power to employ proper persons to execute the work. The persons selected by the commissioners were Dr. O'Donovan and Prof. O'Curry, whose discharge of the duties so assigned them ended only at their death. They were succeeded by others, whose labors are not yet ended; and private

associations have also been busy upon one department of the multifarious materials; so that we have now these two authentic records, edited and annotated with great care: "The Ancient Laws of Ireland," of which two volumes have appeared, the first in 1865; and *Senchus Mor* ("Great Law Compilation") and *Leabhar na g-Ceart* ("The Book of Rights"), published by the Celtic society, with extremely valuable notes by the late John O'Donovan (Dublin, 1847). The two first mentioned volumes can scarcely be called even compilations, because, as their editors avow, they consist of mere fragments, decisions of the brehons, rules and maxims of law, gathered together out of many more or less imperfect manuscripts, of various ages. The principal materials used by the translators are thus described in the preface to the first volume: "I. A comparatively full copy among the manuscripts of Trinity college, Dublin. II. An extensive fragment of the first part, 432, of the Harleian manuscripts in the British museum. III. A large fragment of the latter part among the manuscripts of Trinity college, Dublin. IV. A fragment among the manuscripts in Trinity college." These materials, however, being used with due discrimination, are enough to present in a tolerably consistent form an authentic series of the text books, a much larger, older, and clearer system of the institutions which once prevailed over all western Europe, than any other nation has yet been able to produce from its own archaic resources. Besides the works named above, the student who desires further information concerning the various texts, their origin, their comparative age, and their preservation, may consult O'Curry's published lectures "On the MS. Materials of Ancient Irish History," as delivered in the Catholic university of Dublin.—The principles of the Brehon law were essentially distinct from and incompatible with the feudal; so that when those two systems came face to face on the same small island, it was inevitable that one of the two must succumb. The main basis of every national system of law is of course its land tenure. The possession and inheritance of landed property was regulated by the law called gavelkind (*gavail-kinne*), an ancient Celtic institution, but common to Britons, Anglo-Saxons, and others. By this law, inherited or other property was divided equally between the sons, to the exclusion of the daughters, except in default of heirs male, when females were permitted a life interest. The tenure of land was a tribe or family right, and the whole system of government was far more patriarchal than Teutonic—an indication of an eastern origin. All the members of a tribe or family had an equal right to their proportionate share of the land occupied by the whole. This system created a mutual independence and self-consciousness of personal right and importance, strongly at variance with the subjugation of the Germanic and An-

glo-Norman vassal. One of the most noticeable peculiarities of the Brehon law is the compensation for murder, and for other crimes and wrongs proportionally, called *eric*. This, however, was common to many nations. Its origin is ascribed to the Germans, but the institution was probably far more ancient. We find the *eric* forbidden in the oldest code of laws in existence; and hence it must have existed at an early period of the world's civil history. The law of succession, called *tanaisteacht*, or tanistry, is one of the most peculiar of the Brehon laws. The eldest son succeeded the father to the exclusion of all collateral claimants, unless he was disqualified by deformity, imbecility, or crime. In after ages, by a compact between parents or mutual agreement, the succession was sometimes made alternative in two or more families. The eldest son, being recognized as presumptive heir, was denominated *tanaiste*, that is, minor or second; while the other sons, or persons eligible in case of failure, were termed *righdhamhua*, which literally means king material, or king-makings. The *tanaiste* had a separate establishment and distinct privileges. The primitive intention was that the best man should reign; but practically it sometimes ended in might being taken for right. A very large portion of the *Senchus Mor* relates to the law of distress. The movable wealth of the people consisted mainly of cattle and sheep, a kind of riches easily carried off; and as debts and *eries* were collected chiefly by distraining on the lands of the debtor, the stronger might be easily tempted to oppress the weaker, either by distraining wrongfully or by denying payment and resisting a lawful distress with the strong hand. Therefore we naturally find numerous regulations governing the exercise of this right. Two points are noticeable in this: First, the careful and accurate administration of justice which is indicated by the details of these legal enactments; second, the custom therein sanctioned of the creditor fasting upon the debtor, a custom which still exists in Hindostan. Thus, in some cases, the creditor fasts on the debtor until he is compelled to pay his debt, lest his creditor should die at the door; in other cases, the creditor not only fasts himself, but also compels his debtor to fast, by stopping his supplies. Elphinstone describes this as used even against princes, and especially by troops to procure payment of arrears. This singular method of levying money due is called in Irish *acharitan*, and is known in Cabool and Afghanistan as *dherma*. The student of these laws will find them pervaded on the whole by a spirit of humanity and gentleness. We find this more particularly the case in studying the laws regulating the domestic relations of the family, which, being the unit of which society is but an aggregate, is the most vital and important part of all human arrangements. Ample provision is made for the mutual protection of husband and wife, and the reciprocal rights and

duties of parent and child are minutely defined and carefully guarded. There is also found a universal respect and tenderness toward women, a thing rare in that age. Here is one passage from the *Senchus*: "In the connection of equal property, if with equal land and cattle and household stuff, and if their marriage state be equally free and lawful, the wife in this case is called the wife of equal rank. The contract made by either party is not a lawful contract without the consent of the other, except in cases of contracts tending equally to the welfare of both; such as the alliance of co-tillage with a lawful tribe when they (the couple) have not the means themselves of doing the work of ploughing; the taking of land; the collection of food; the gathering for the festivals; the buying of breeding cattle; the collecting of house furniture; the collecting of litters of pigs; the buying of stacks and other necessities. . . . Each of the two parties has the power to give refection and feast according to their respective dignity." The maxims of law relating to the enforcement of the rights of women are very precise. In case of separation, adequate protection was thrown around the wife's right of property. If her property was equal to that of her husband at the time of marriage, she took an equal moiety of the collective lands, goods, and chattels, and in case of dairy produce and the proceeds of the loom two thirds. If the property had originally belonged wholly to the husband, the wife was entitled to one third on her separation; and if it had been her own before marriage, to two thirds. The institution of the family, on which all clanship rests, is not only found here surrounded by much sanctity and careful guardianship, but the family relation is even extended outside of the mere household, by two institutions called *fosterage* and *gossipred*. When a child was put out to be fostered in another family of the same clan, he grew up with two mothers and two sets of brothers and sisters, and often was more attached to the foster

mother and foster brother than to those of his own household. It was a relation well known in other nations of the west, especially among those other Gael, the Highlanders of Scotland; but nowhere was it regulated by such elaborate laws, as to the food, clothing, and education of the foster child, and its training, if a boy, in all manly exercises, if a girl, in feminine accomplishments suitable to their degree, as it may here be found regulated by the brehons. *Gossipred*, or the relation between a child and his godfathers and godmothers, was also a substantial and legal tie, inferring obligations, not a mere sentimental notion calling only for christening presents. Then there was a literary fosterage, in use only among the professional classes, that is, the *fileas*, *ollamhs*, and *brehons*; concerning which here is a curious extract: "The social connection that is considered between the foster pupil and the literary foster father is, that the latter is to instruct him without reserve, and to prepare him for his degree, and to chastise him without severity, and to feed and clothe him while he is learning his profession, unless he obtains it from another person, and from the school of Fenius Forsaidh onward this custom prevails; and the foster pupil is to assist his tutor in poverty and to assist him in his old age, and the honor price of the degree for which he prepares him and all the gains of his art while he is learning it, and the first earnings of his art after leaving the house of his tutor, are to be given to the tutor."

BREIDENBACH, Bernhard von, a priest of Mentz, who visited Palestine about 1488, died in 1497. On his return to Germany he wrote in Latin an account of his travels, which was published in several editions before his death. This work was accompanied by engravings of the scenery, costumes, and animals of the Holy Land, and contained several oriental alphabets, said to have been the first ever printed.

BREISACH. **L. Alt**, a town of Germany, in Baden, on the Rhine, 12 m. W. of Freiburg;

Alt Breisach.

pop. in 1867, 3,272. It is well fortified, and was formerly a bulwark of Germany on the upper Rhine. It has a fine old cathedral, and the inhabitants are engaged in shipping and in the cultivation of tobacco. The town was captured by Bernhard of Saxe-Weimar in 1638 after a long siege, ceded to France in 1648, and restored to Germany in 1697. The French again held it from 1703 to 1715. **II. Neu** (Fr. *Neuf-Brisach*), a town of Germany, in Alsace, opposite the preceding, about 2 m. W. of the Rhine, on the Rhône and Rhine canal; pop. in 1866, 1,981. After Alt Breisach had been restored to the German empire, Neu Breisach was, by order of Louis XIV., strongly fortified by Vauban. Fort Mortier, 2 m. N. E. of Neu Breisach, capitulated to the German army on Nov. 7, 1870, and three days later the fortress itself surrendered, when 100 officers, 5,000 men, and 100 pieces of ordnance fell into the hands of the victors.

BREISGAU, or **Brisgau**, an old division of Germany, in the S. W. of Swabia. For a long time it was under the authority of the counts of Breisach, and subsequently under the dukes of Zähringen. It was afterward added to the Austrian dominions, and by the treaty of Presburg in 1805 it was ceded to the elector of Baden, excepting a small portion assigned to Württemberg, and subsequently acquired by Baden. It contains 17 towns, among them Alt Breisach and Freiburg (Freiburg im Breisgau). Iron, copper, and lead are extensively worked in Breisgau, and the forest districts are famous for the manufacture of clocks and other articles in wood.

BREISLAK, **Scipione**, an Italian geologist, of German parentage, born in Rome in 1748, died in Milan, Feb. 15, 1826. He has been called abbé from having been destined for the church, though he never became a priest. He early filled a scientific chair at Ragusa, subsequently became professor at the *collegio Nazareno* in Rome, made considerable researches in the volcanic regions of Italy and France, spent some time in Paris with Cuvier, and was appointed by Napoleon director of the powder and saltpetre works in Italy. His works, in which he opposed the system of the Neptunists without indiscriminately accepting that of the Vulcanists, include *Topografia fisica della Campania* (Florence, 1798); *Istituzioni geologiche* (Milan, 1818); *Descrizione geologica della Lombardia* (1822); and *Sopra i terreni tra il Lago Maggiore e quello di Lugano* (1838). His rich geological collections he bequeathed to the Borromeo family.

BREITHAUP, **Joachim Justus**, a German clergyman, born at Nordheim, Hanover, in 1658, died March 16, 1732. He was professor at Halle from 1691 to 1705, and published *Institutiones Theologicae* (1694), *De Credis et Agendis* (1716-'32), and several hymns which were translated into English by John Wesley.

BREITKOPF, **Johann Gottlob Immanuel**, a German printer, born in Leipsic, Nov. 23, 1719,

died there, Jan. 28, 1794. His father was a bookseller, printer, and type founder, and brought up his son as such. The latter changed the form of the types then in general use, improved the composition of type metal and the mechanism of printing presses, and endeavored, unsuccessfully, to print music, geographical maps, and portraits with movable type. He wrote an essay on the history of printing, and labored for several years on a more elaborate work on the same subject, which he did not live to complete; but he published several other works, including one on bibliography and bibliophily (1793). His establishment was continued by his son, Christoph Gottlob, in partnership with Gottfried Christoph Härtel, under the firm name of Breitkopf and Härtel.

BREMEN, one of the three free cities of Germany, forming with its territory a state of the empire, situated on the Weser, 30 m. from its mouth, and 57 m. S. W. of Hamburg; area of the state, 99 sq. m.; pop. in 1871, 122,565, of whom 82,950 resided in the city of Bremen, 10,594 in the town of Bremerhafen, 3,554 in

Statue of Roland.

the town of Vegesack, and 25,467 in the rural districts. More than 97 per cent. of the inhabitants are Protestants. The new and the old town, on opposite banks of the river, are connected by handsome bridges. No dredging being used to deepen the channel, the bed of the river continually rises by the deposits brought down, and the dike is consequently raised year by year, so that in time the bottom of the river will be on a level with the streets. Among the noteworthy buildings are the cathedral, built in 1050 by Archbishop Adalbert, with a tower 324 ft. high, having one of the finest organs in Germany, and a vault (*Bleikeller*) which has the property of preserving free from decomposition, after the lapse of ages, bodies interred in it; the church of St. Anscarius; the council house, with the celebrated wine cellar

and casks, called the rose and the twelve apostles, filled with fine hook, some of which is a century and a half old; the Roland statue, 18 ft. high; the guildhall, called the *Schütting*;

Council House.

the theatre, the post office, the exchange, and the museum. The statue of Gustavus Adolphus was placed in one of the public squares in 1856. Among the other public buildings are the commercial school, two orphan asylums, the infirmary, the naval academy, the institution for deaf mutes, the normal school, the drawing school, the art gallery, the observatory (founded by the astronomer Olbers, a native of the town, to whom a monument was erected in 1850), and the gymnasium. The "Library Association" undertakes to insure that all libraries belonging to the city or to special corporations are accessible to the entire population. There is a merchants' exchange, a bank of issue, a discount bank, several insurance companies, a commercial court, and public institutions for the security and comfort of emigrants. A Lloyd for northern Germany (*der Nord-Deutsche Lloyd*), after the plan of the *Lloyd Austriaco* of Trieste, was founded in 1856. Ship building is carried on to a greater extent than in any other German port. Sugar refineries, iron foundries, lard-boiling, manufactures of oil, soap, and sail cloth, and cotton spinning, are also carried on. More tobacco is imported here than at all the other German ports, the quantity amounting to about 24,000,000 lbs. a year, and cigars are largely manufactured.—The improvements in the navigation of the Weser and its confluent, and the railway connections, have placed Bremen in direct communication with the heart of Germany. Its prosperity depends mainly upon its trade with the rest of the empire, and with the United States and Great Britain. The gold thaler, in which accounts are kept, is equivalent to 79 cents, American coin. The estimated revenue in 1871 was 2,281,463 thalers; expenditures 2,052,775, about one half on account of the public debt, amounting in 1870 to 11,584,513 thalers, of which 4,000,000 were a railway loan, paying 4½ per cent. interest. The com-

merce in 1870 was: exports, 94,920,000 thalers; imports, 90,950,000; of which were with the German Zollverein, exports 41,980,000, imports 28,370,000; the United States, exports 17,520,000, imports 29,960,000; Great Britain, exports 4,120,000, imports 12,100,000; Hamburg, exports 1,870,000, imports 4,050,000; Austria, exports 7,390,000, imports 2,110,000; Russia, exports 6,760,000, imports 1,040,000; Holland and Belgium, exports 2,550,000, imports 1,460,000; France, exports 440,000, imports 540,000; the Antilles, exports 940,000, imports 2,050,000; the trade with other countries being small. The average annual exports from 1861 to 1870 were 78,610,000 thalers, imports 82,920,000; the largest amount was in 1869, when the exports were 94,920,000, imports 103,810,000. In 1869 the total trade with transatlantic ports was, exports 20,813,082 thalers, imports 38,687,533; with European ports and the Levant, 18,516,102; by land and river, exports 52,985,587, imports 83,816,220. In 1869 there were plying to and from the port of Bremen 274 vessels, of 238,148 tons, and 26 ocean steamers, of 51,725 tons. In 1868 the privilege was conceded to Bremen and Hamburg of remaining free ports, exempt from the German customs limits, in consideration of which the state engaged to pay to the Zollverein a tax proportioned to its trade. Bremen is the chief German port for emigration, the emigrants going almost entirely to the United States. In 1843 there were 9,844 emigrants; 1844, 19,863; 1845, 31,158; 1846, 32,372; 1847, 33,628; 1848, 29,947; 1849, 28,629; 1850, 25,838; 1851, 37,493; 1852, 58,551; 1853, 58,111; 1854, 76,875; 1855, 31,550; from 1856 to 1860, average 82,450; 1861-'5, average 20,397; in 1866, 61,877; 1867, 73,971; in 1868, 66,433; in 1869, 68,519. The total number of emigrants from 1830 to 1870 was 1,196,363.—Bremen is connected by railways with the whole interior of Germany, and also with Bremerhafen, 30 m. distant, which is now its port; for the Weser having become too shallow for large vessels to ascend, it became necessary to abandon Vegesack, which had been the port since the 16th century.—Bremen has one vote out of 58 in the Bundesrath, or federal council of the empire, and one out of 382 in the Reichstag or diet of the empire. Its local government is composed of a senate of 18 members, of whom at least 10 must be lawyers and 5 merchants; and a *Bürgerschaft* or assembly of the citizens, consisting of 150 members, of whom 16 are chosen by the citizens who have attended the university, 48 by the merchants, 24 by the trades, 30 by the other inhabitants of the city, 6 by Vegesack, 6 by Bremerhafen, and 20 by the rural districts. The assembly is divided into committees, and is presided over by members of the board of aldermen, in whom is vested a portion of the executive power. Two burgomasters, elected by and from the senate, direct the affairs of state, through eight departments: foreign affairs, church and education,

justice, finance, police, medical and sanitary administration, military affairs, commerce and shipping; all the ministers are senators. In 1854 a law was enacted admitting Jews to the right of citizenship.—Bremen was founded by Charlemagne in 788, and endowed with a bishopric, which was subsequently raised to an archbishopric. In the course of time the city increased in strength, wrested the temporal power from the hand of the church, and became one of the early participants in the league of the Hanse towns. It conquered a number of Norwegian and Livonian ports, founded Riga in 1158, took part in the conquest of Prussia, extorted commercial privileges from all ports between Bremen and Amsterdam, from England and Flanders, and subjected to its control a large strip of land on both banks of the Weser. In common with Hamburg, it purged the North sea of pirates. It was one of the earliest cities to decide for Protestantism, but religious dissensions within the city, and finally the thirty years' war, brought the archiepiscopal territory under Swedish sway, with the title of duchy. The city itself was twice unsuccessfully besieged by the Swedes (1654 and 1666). Both the duchy and city were conquered by the Danes in 1712; the former was subsequently acquired by Hanover, and the latter restored to its independence. In the Napoleonic wars, when the city suffered much, its volunteer militia were among the earliest and bravest defenders of German independence. The treaties of Vienna made it a member of the Germanic confederation, after the dissolution of which in 1866 it joined the North German union, and four years later the German empire.

BREMER, a N. E. county of Iowa, intersected by the Cedar and Wapsipinicon rivers; area, 480 sq. m.; pop. in 1870, 12,528. The Cedar Falls and Minnesota railroad traverses the county. The soil is of good quality, well watered, and abundantly supplied with timber. The chief productions in 1870 were 527,638 bushels of wheat, 423,362 of Indian corn, 387,658 of oats, 15,493 of barley, 77,349 of potatoes, 26,550 tons of hay, 20,101 lbs. of wool, and 400,791 of butter. There were 4,946 horses, 5,101 milch cows, 5,223 sheep, and 9,424 swine. Capital, Waverley.

BREMER, Fredrika, a Swedish novelist, born near Abo, in Finland, Aug. 17, 1801, died at Arsta, near Stockholm, Dec. 31, 1865. Her father was a wealthy merchant, and on the annexation of Finland to Russia in 1809 removed with his family to Sweden. Fredrika was carefully educated, resided for some time in Norway with the countess Sonnerhjelm, and to complete her education was sent for a year to Paris. On her return she became a teacher in a female academy at Stockholm. She began at the age of eight years to write verses, and in 1824 published at Stockholm her first novel, "The Neighbors," which was soon translated into German, French, Dutch, and Russian, and in 1842 into English

by Mary Howitt, who also translated her subsequent works. Previous to 1849 she had published "The Home," "The Diary," "The H—— Family," "The President's Daughter," "Nina," "Brothers and Sisters," "Life in Dalecarlia," and "The Midnight Sun." In 1849 she visited the United States, where she was cordially received. She spent two years in travelling through the country, and made a short visit to Cuba. Her observations were recorded in a work entitled "The Homes of the New World," which was published simultaneously in Sweden, England, and the United States in 1853, and was exceedingly complimentary to this country and to her American friends. On her return to Europe she spent some time in England, and published at Altona in 1852 an account of her visit under the title of "England in 1851." From England she returned to Sweden, where she wrote two more novels of home life, "Hertha" (1856) and "Father and Daughter" (1858). In 1857 she went to the south of Europe, and the result of her travels was published in 1860 under the title of "Two Years in Switzerland and Italy." From Italy she went to Palestine, Greece, and Turkey, and in 1863 published her observations on those countries. A German edition of her works in 30 volumes was completed in 1864.

BREMERHAFEN, or *Bremerhaven*, a town of Germany, belonging to Bremen, of which it is the port, situated on the estuary of the Weser, at the mouth of the river Geeste, 30 m. N. N. W. of Bremen, with which it is connected by railway and the Weser; pop. in 1871, 10,594. The channel of the Weser having become so filled up as to be impassable for large vessels, the spot on which Bremerhafen stands was acquired from the kingdom of Hanover in 1827, and the town was established in 1830. The port, which is accessible for the largest vessels, consists of an outer harbor, a sluiced dock, and an inner harbor. Bremerhafen has become the chief point from which German emigrants sail for America. (See **BREMEN**.) For their accommodation the *Auswandererhaus* was erected in 1849 by the authorities of Bremen, capable of sheltering 2,500 persons at a time, and of feeding 6,000 a day. The town is defended by Fort Wilhelm on the opposite bank of the river. Lines of steamers connect it with London, Hull, and New York.

BRENDAN, or *Brandanus*, an Irish saint, died in 578. He founded religious establishments in Ireland and England, and is the legendary hero of voyages undertaken under the protection of an angel, narratives of which, in Latin and old French, were published in Paris in 1836, from original MSS. of the 11th or 12th century. Blommaert's *Oudvlaemschen Gedichten* (Ghent, 1838-'41) gave a version of another MS. said to have existed in old German. A Low-German dramatic version and German translation of the Latin appeared at the end of the 15th century.

BRENDEL, Franz, a German writer on music, born at Stolberg, Nov. 26, 1811, died in Leipzig, Nov. 25, 1868. He was successively the editor of the *Neue Zeitschrift für Musik* and teacher at the conservatory of Leipzig, and published *Die Musik der Gegenwart* (1854), *Geschichte der Musik in Deutschland, Italien und Frankreich* (4th ed., 2 vols., 1868), and other works. He was a follower of Wagner.

BRENNER, a mountain of Austria, in Tyrol, between the Inn, the Aicha, and the Adige, 6,788 ft. high. The railway from Innsbruck to Botzen, thence to Trent and Verona, crosses the Brenner pass at the height of 4,775 ft. It was constructed by the Austrian government at a cost of \$140,000 a mile, and completed in 1867. There are 23 tunnels on the road, one of which is 2,800 and another 2,200 ft. long.

BRENNUS. **I.** The leader of the Senonian Gauls, who defeated the Romans at the Allia, and took Rome, about 390 B. C. Having quit- ted the city upon receiving a ransom for the capitol, he returned home with his gold. A popular legend, however, relates that a Roman army under Camillus appeared at the moment the gold was being weighed, defeating and slaying Brennus and his followers. **II.** Another warrior of the same name was a leader of the Gauls who made an irruption into Macedonia and Greece, 279 B. C. Having defeated in the following year Ptolemy Ceraunus, and after- ward Sosthenes, the chief who succeeded the Macedonian king, he crossed the pass of Ther- mopylae, and invaded the heart of Greece, but was repulsed in an attack on Delphi with great loss, and subsequently died by his own hand.— By modern historians Brennus is thought to have been, not a proper name, but merely a Gallic title signifying king, chief, or general.

BRENTA (anc. *Medoacus Major*), a river of northern Italy, rises in a small lake about 8 m. S. E. of Trent in Tyrol, flows E. by N. and then E. by S. to a point about 20 m. from its source, where it crosses the boundary of Italy, turns S. near Primolano, and follows a southern course as far as Bassano. Here it emerges from the deep mountain gorges through which it has thus far flowed, and passes S. and S. E. across the level country of the province of Venice. At Limena, and at a point about 6 m. E. of Padua, canals connect it with the Bacchiglione; and at Dolo, 9 m. E. of Padua, another canal runs S. and S. E. from the Brenta to Brondolo at the southern end of the Venetian lagoon. This last-named channel was cut to break the force of the current at the principal mouth of the river; for the Brenta, continuing its course, flows into the lagoon exactly opposite the city of Venice. But this was found insufficient, and a second canal parallel to the first was cut from La Mira, a few miles further east. The main bed of the Brenta below La Mira was at the same time made into a canal with embank- ments and locks; this part of the river is called Brenta Morta, and forms the principal means for the transportation of freight between Venice

and Padua. The whole length of the river is about 120 m.

BRENTANO, Clemens, a German poet and novelist, born at Frankfort-on-the-Main, Sept. 9, 1777, died at Aschaffenburg, July 28, 1842. He studied at the university of Jena, and after- ward taught there as a *Privatdocent*. While here he married in 1804 Sophie Mereau, the divorced wife of a professor, a woman who shared many of the fantastic theories he had already begun to advance, and had written poems and romances of some merit. She died little more than a year after the marriage, in consequence of which he fell into a singular misanthropy. After making his home successively at Frankfort, Heidelberg, Vienna, and Berlin, he withdrew entirely from the world in 1818, retiring to the village of Dülmen near Münster. In the last years of his life, however, he again visited the larger towns, living in Rat- isbon, Munich, Frankfort, and Aschaffenburg. His works, the first of which were published under the pseudonyme of Maria, were wild and fantastic. His original and audacious vagaries, together with the peculiarities of his sister Bet- tina von Arnim, his wife, and others connected with him, made the family name almost prover- bial, and "mad as a Brentano" was a not un- common phrase among German wits. Clemens Brentano's principal works are: *Satyren und poetische Spiele* (Leipzig, 1800); *Gedeci, oder das steinerne Bild der Mutter* (2 vols., Frank- fort, 1801); *Die lustigen Musikanten* (a mu- sical drama, Frankfort, 1803); *Ponce de Leon* (Göttingen, 1804); *Der Goldjude* (Heidelberg, 1809); *Die Philister vor, in und nach der Geschichte* (Berlin, 1811); *Die Gründung Prags* (Pesth, 1815); *Victoria und ihre Ge- schwister* (Berlin, 1817); *Schneeglöckchen* (Ham- burg, 1819); *Geschichte vom braven Kaspar und dem schönen Annerl* (2d ed., Berlin, 1851). Brentano also aided his brother-in-law Achim von Arnim in the preparation of the *Knaben- wunderhorn*.

BRENTFORD, a market town of England, and nominal capital of the county of Middlesex, 7 m. W. S. W. of London; pop. in 1871, 20,279. It is situated on the Thames, is connected by a bridge with Kew, and stands on the line of the Great Western railway. Here are the water works of the West London company, with a chimney 150 ft. high. Near by is Sion house, the seat of the duke of Northumberland, and Osterley park, of the countess of Jersey. Al- though usually considered the county town, the magisterial business of the county is transacted at Clerkenwell. It has some trade, which is facilitated by the Grand Junction canal, con- necting with the Brent river. The town takes its name from the ford, crossed at an early pe- riod by a bridge, in aid of which Edward I. in 1280 granted a toll for three years. In 1016 Edmund Ironsides, after driving the Danes from London, totally defeated them at Brent- ford; and here in 1642 Prince Rupert defeated the parliamentarians under Col. Hollis.

BRENTON, Edward Pelham, captain in the British navy, born July 18, 1774, died April 6, 1839. He was on active service during the wars with France, 1793-1815. He wrote a life of the first Earl St. Vincent, and a "Naval History of Great Britain from 1783 to 1822." He founded the "Children's Friend Society."

BRESCHET, Gilbert, a French physician, born at Clermont-Ferrand, July 7, 1784, died in Paris, May 10, 1845. He was professor of anatomy in the school of medicine at Paris, attending surgeon to the Hôtel Dieu, and member of the academy of sciences. He wrote much upon various anatomical, physiological, and surgical subjects; his most valuable work is that upon the spinal veins, published in 1819 and enriched with carefully executed plates.

BRESCIA. I. A province of Italy, in Lombardy, bounded N. by Bergamo and Tyrol, E. by Verona and Mantua, S. by Cremona, W. by

Lodi and Bergamo; area, 1,784 sq. m.; pop. in 1871, 450,750. The province is mountainous or hilly in the north, and level in the south. It is watered by the Oglio, and its affluents the Mella and Chiese. It embraces Lake Iseo and borders on Lake Garda. The soil is highly fertile. One of the most important branches of industry is the production and manufacture of silk; wool of superior quality is also produced. There are manufactures of woollen and cotton goods, metals, and porcelain. Brescia has long been famous for its iron and steel manufactures, especially of weapons and firearms, whence it was called in former times *l'Armata*. Wheat, maize, hay, butter, cheese, flax, wine, oil, and chestnuts are important productions. The trade of the province is principally carried on in the capital. Among the principal towns are Lonato, Montechiaro, and Salò. **II.** A city (anc. *Brixia*), capital of the province, 50 m. E.

Brescia.

by N. of Milan; pop. in 1871, 38,906. It stands on the rivers Mella and Garza, at the foot of a hill. The strong castle on the top of the hill was in former times called the falcon of Lombardy. It is a well built town, noted for its numerous fountains. It is connected by railway with Verona and other Italian cities, and by the railway through the Brenner pass of the Alps with Austria and the rest of Europe. The ancient cathedral and the other churches contain many paintings of the great Italian masters. The new cathedral, or *duomo nuovo*, was begun in 1604, but the vaulting of the cupola was only completed in 1825. The chief ornament of the church of Santa Afra is "The Woman taken in Adultery," by Titian. Among the public buildings is the palazzo della Loggia in the piazza Vecchia, intended for the town hall, the beautiful façade of which suffered much

from bombardment in 1849. The palazzo Tosi contains, among many famous pictures, the "Saviour," by Raphael. The picture galleries in the palazzi Averoldi, Fenaroli, Lecchi, Martenigo, and in other palaces, are noted for their artistic attractions. A whole street, the corso del Teatro, has the fronts of the second stories decorated with Scriptural, mythological, and historical paintings. The Quirini library, founded in the middle of the 18th century by Cardinal Quirini, contains nearly 100,000 volumes, besides a vast collection of manuscripts and objects of antiquity. The most unique monument of Brescia is the cemetery (*campo santo*), the finest in Italy, built in 1810. Brescia is the seat of the provincial government, of a bishopric, and of a tribunal of commerce. There are various charitable institutions, a theological seminary, gymnasia, a lyceum, a botanical gar-

den, cabinets of antiquities and natural history, an agricultural society, several academies (the philharmonic being one of the oldest in Italy), a casino, a fine theatre, and a large structure outside of the town for the annual fair. A Roman temple of marble was excavated in the vicinity in 1822.—The town was originally inhabited by the Cenomani, and under the Romans became a flourishing colony of Transpadane Gaul. It was pillaged by Attila, and eventually passed into the hands of the Lombards. Otho the Great raised it to the rank of a free imperial city. It joined the Lombard league against Frederick Barbarossa, was besieged by Frederick II., was for a long time distracted by the contests between the Guelphs and the Ghibellines, and many times changed masters. In 1426 it was taken by Carmagnola; in 1488 besieged by Piccinino; in 1509 it surrendered to the French; in 1512 it rose against the conquerors, but was recaptured and sacked by Gaston de Foix. Occupied soon after by Venice, it remained in possession of that republic till its downfall in 1797. During the Napoleonic era it was the capital of the department of Mella, and in 1814 was made over to Austria. In 1849 the Brescians rose against Austria; the town was bombarded, March 30, by Haynau, and held out until noon of April 2, when it was compelled to surrender, and to pay a ransom of \$1,200,000. After the war of 1859 the city and province were incorporated with the kingdom of Italy.

BRESLAU (Polish, *Wrocław*), a city of Prussia, capital of an administrative district of the same

name in Silesia, at the junction of the Ohlau with the Oder, 180 m. S. E. of Berlin; pop. in 1871, 208,025, of whom about 58 per cent. are Protestants, 33 per cent. Roman Catholics, and 7 per cent. Jews. The Oder is navigable from Breslau for large boats. It is the second city in size and importance in Prussia. Its revenue in 1871 amounted to 30,251,651 thalers. It is connected by railway with Cracow, Warsaw, and Vienna, with Berlin and Leipsic, with Posen and Stettin, and with Schweidnitz and the rich manufacturing and mining districts of the Riesengebirge. It is an important emporium, has many mercantile establishments and large annual fairs, and is the most considerable wool market in the world. All the agricultural, manufacturing, and mineral produce of Upper and Middle Silesia comes to its market. Cotton, linen, and woollen goods, metals, coal, spirits, glass, paper, grain, and dyestuffs are among the principal articles of trade. In the city itself there are manufactories of dyed goods, and of leather, needles, liquors, refined sugar, tobacco, oil, cotton, linen, fine iron, gold and silver ware, broadcloths, laces, earthenware, straw hats, beer, vinegar, &c. The town is well built, and has a circumference of 11 m. It has many remarkable buildings, among which are St. Elizabeth's church, begun about 1250, with a tower 354 ft. high, and a celebrated organ, the church of Mary Magdalen, with two towers, the Reformed church, the Catholic cathedral, with many monuments of the 13th century, the *Sandkirche*, the church of St. Dorothea, and St. Michael's church, recently built by the prince

Breslau.

bishop; the council house, the university building, the royal palace, the new hall of the diet, the Jesuits' college, now belonging to the university, the residence of the prince bishop, the palace of Count Henkel, and the central railway depot. The city theatre was burned

in 1865, but soon rebuilt. In the market place is a statue of Frederick the Great, and one of Blücher in the Blücher place. The streets are well paved and broad, with granite sidewalks,

Town Hall.

and lighted with gas. The benevolent institutions are more numerous and better provided than in most cities of Germany. There are four gymnasia, a seminary for classical and one for popular teachers, an architectural and artistic academy, and a university founded in 1702 and enlarged in 1811, which possesses a library of upward of 300,000 volumes and many manuscripts, a botanical garden, an observatory, a clinical institute, and various scientific collections. There is a missionary and a Bible institution, and the Leopold's or imperial society of naturalists has its seat here. A zoological garden was opened in 1865. There are four large libraries besides that of the university, several small but valuable picture galleries, a numismatic cabinet, 18 hospitals, and four orphan asylums.—Breslau is built on originally Polish territory; it was founded about 1000. When in 1163 the surrounding territory was separated from Poland by the emperor Frederick I., who intervened in a quarrel of the sons of Ladislas II., and made two of them, Konrad and Boleslas, independent dukes of what is now Silesia, a city charter was given to Breslau, which was already inhabited by a large population of Germans. In 1335 it came into the possession of the Bohemian kings, and in 1526, with Bohemia, into that of the Austrians, from whom Frederick the Great wrested it by the invasion of 1741 and the seven years' war. Like all Silesia, it shared the good and bad fortune of Bohemia in the 14th, 15th, and 16th centuries, and succumbed in two attempts of the citizens to make themselves independent of the archbishops and the patrician families. It early embraced the reformation. In 1742 the first peace between Frederick the Great and Austria was concluded here. In 1757 the Austrians defeated near the city a weaker Prussian army, but were driven out again in the same year by

Frederick's victory at Leuthen. In 1760 Tanzenzien bravely defended the town against London's besieging army. In 1806-'7 it was beleaguered by the French under Vandamme, taken, and the fortifications demolished.

BRESSANI, Francesco Giuseppe, an Italian missionary, member of the society of Jesus, born in Rome in 1612, died in Florence, Sept. 9, 1672. He was sent to Canada, and spent two years among the Indians near Quebec. In the spring of 1644 he was directed to go on a mission to the Hurons. On the way he was captured by a party of Iroquois, who subjected him to fearful torture. They then made him over to an old squaw, to take the place of a deceased relative; she sent him to the Dutch of Fort Orange, now Albany, who paid a large ransom for him, kept him until his strength was restored, and then put him on board a vessel bound for La Rochelle, where he arrived on Nov. 15. In the following spring, maimed and disfigured, he returned to Canada, and was again sent to the Hurons, with whom he remained till 1650, when, his health being broken down, he returned to Italy. His *Relazione dei missionarij della compagnia de Gesu nella Nuova-Francia* (Macerata, 1653) was translated into English in Montreal in 1862.

BRESSANT, Jean Baptiste Prosper, a French actor, born at Châlon-sur-Saône, Oct. 24, 1815. He made his début in Paris in 1835, and after acting for long terms at the Variétés and Gymnase theatres of that city and in St. Petersburg, he became in 1854 a member of the Comédie Française. He has been distinguished as a light comedian both in the modern and the classic drama; also in such parts as Richelieu in *Dumas's Mlle. de Belle-Isle*.

BRESSION, Charles, count de, a French diplomatist, born in Paris, died by his own hand in Naples, Nov. 2, 1847. His father was one of the chief clerks in the department of foreign affairs. During the restoration he was sent on a special mission to the republic of Colombia. After the revolution of 1830 he entered the service of Louis Philippe, and was appointed chargé d'affaires and afterward minister in Berlin. In 1834 he was made minister of foreign affairs, and afterward sent again to Berlin as ambassador. During this embassy, in 1837, he negotiated the marriage of the duke of Orleans with the princess Helen of Mecklenburg, and was created a peer. In 1841 he was made ambassador to Madrid, where he brought about the marriage of the duke of Montpensier with the sister of Isabella II., and of the queen herself with her first cousin, the infante Francisco de Assis. For this service Bresson expected to be rewarded by the embassy to London, but failed to obtain it, and was sent in 1847 as ambassador to Naples. The king of the Two Sicilies, whose hope of securing the hand of a Spanish princess for one of his brothers had been frustrated by Bresson's negotiations, received him in the most offensive manner; and the affront, preying upon a mind

already smarting under humiliation, led him to commit suicide.

BREST, a fortified town of France, in Brittany, department of Finistère, on a bay of the Atlantic, 310 m. W. of Paris; pop. in 1866, 79,847. It is the chief station of the French marine, and one of the first military and naval ports in Europe. It stands on the N. side of a landlocked haven, accessible only by the Goulet, a narrow fortified entrance about a mile wide, divided in the middle by a rocky island. The town is built on the summit and sides of a projecting ridge, some of the streets being so steep that they can be traversed only on foot. A deep narrow creek runs up from the harbor behind this ridge, separating the town on its left bank from the suburb of Recouvrance on its right, communication being kept up by an iron bridge 65 ft. above high-water mark, with a swing opening to allow ships of war to pass. Just

above the mouth of the creek, which is defended by several tiers of batteries, is an old castle. This creek, which forms the inner port, is so narrow that there is barely space for the merchant vessels, and for 30 or 40 ships of war moored side by side. Above the castle the shores on both sides are enclosed by a high wall, separating the dockyard from the town. Around the harbor run long quays at which the largest vessels can lie, and five artificial basins are excavated out of the rock. There is also a commercial harbor, with a breakwater, extending far into the roadstead. The dockyard is situated on both sides of a narrow creek winding between steep rocks, which have been pared down so as to afford space for the buildings, quays, and yards. Three large dry docks have been cut out of the solid rock. On one side of the creek are the magazine, sail loft, rope yard, and hospital; on the other the foundry and

Brest—Swing Bridge.

sailors' barracks. Slips for building vessels occupy the level space at the water's edge; and above these are the steam-engine factory, from which machinery is lowered into the vessels. On the Recouvrance side of the harbor are the forges, furnaces, and workshops necessary for the construction and repair of steam engines. The galleys or hulks for convicts no longer exist, the prisoners confined in them having been removed in 1860 to the penal colony of Cayenne. Outside the dockyard is the marine hospital, admirably arranged, containing 26 wards, each having 53 beds, attended by a large body of *religieuses* called *sœurs fidèles de la sagesse*, who are lodged within the building. The roadstead of Brest lies between the promontory of Finistère on the N. and the peninsula of Quélern on the S., which have a space of only 1,749 yards between them, and this is still further contract-

ed by a rock in the centre, which compels vessels to pass directly under the batteries on each side. The roads, consisting of several bays, are about 15 m. long, and in some places 8 m. broad; and although there are many shoals and sand banks, several hundred vessels can anchor there. The harbor is so fortified as to be apparently impregnable against any naval attack. Fully 400 heavy guns can be brought to bear from the batteries outside the Goulet, while 60 more sweep the anchorage within. Besides these the fortifications of the town itself mount more than 400 cannon, and behind is an intrenched camp defended by heavy guns. Brest has a considerable trade in wheat, oats, wine, brandy, beer, sardines, mackerel, and water-proof goods. It is connected with America by a submarine cable, terminating near Duxbury, Mass. It has a city hall, chamber of commerce, observatory,

naval school, cabinet of natural history, botanical garden, communal college, public library, and marine library, with 27,000 volumes.—Brest was of some importance during the middle ages. The old castle belonging to the dukes of Brittany fell into the possession of the English, and sustained a long siege by the French under Duguesclin and Clisson. In 1395 it was surrendered by Richard II. in consideration of 12,000 crowns. It was made a fortified port by Richelieu in 1631, and the fortifications were modernized by Vauban in 1680-'88. In 1694 a combined English and Dutch fleet appeared in the roadstead and disembarked a strong force, hoping to take the fortifications by surprise; but a storm dispersed the fleet, and most of the land force were killed. In 1757 an English fleet of 19 vessels approached the mouth of the Goulet, and 20,000 men were landed, but made no attack. Since that time Brest has never been seriously threatened by an enemy; but it was blockaded in 1794 by Admiral Howe, who won a great naval victory in its neighborhood (June 1).

BREST LITOVSKI (Pol. *Brzesz Litewski*), a fortified town of Russia, in the government and 110 m. S. of Grodno, on the right bank of the river Bug; pop. in 1867, 22,793, of whom one half were Jews. It was formerly the capital of a Lithuanian palatinate, and contains an old castle, a Jewish high school, and a military school, and has a considerable transit trade. In 1794 Suvaroff here gained a victory over the Poles.

BRETAGNE. See BRITTANY.

BRETHREN, Bohemian. See BOHEMIAN BRETHREN.

BRETHREN, Plymouth. See PLYMOUTH BRETHREN.

BRETHREN, White, a sect of the 15th century, who first appeared in the Italian Alps about 1399, and were headed by a priest, probably a Spaniard, although some say that he was a Provençal, others that he was a Scotchman. He claimed to be the prophet Elias. He and his followers were arrayed in white, and carried large crucifixes from which a bloody sweat appeared to exude. He affirmed that it was his mission to announce the speedy destruction of the world by an earthquake. He commenced his ministrations in Lombardy, and thence extended them to the Ligurian Alps. His success was at first great. He entered Genoa at the head of 5,000 followers, and the excitement spread to Lucca, Pisa, and Florence. Their leader prescribed and practised mortification and rigorous penances, and endeavored to effect a renewal of the crusades. But Pope Boniface IX. caused him to be apprehended and burnt at the stake, whereupon his followers dispersed, and the sect became extinct, having existed only a few months.

BRETHREN AND CLERKS OF THE COMMON LIFE (*Fratres et Clerici Vitæ Communis*), a religious order established in the Netherlands near the close of the 14th century, by Gerhard de Groot. It was divided into two classes, the

lettered and the illiterate. The first class was mainly composed of the clergy, who gave themselves to study and copying books, while the second class engaged in manual labor. They adopted the rule of St. Augustine, and gave up their property to the common use. Their vows were not considered binding for life. They were sanctioned by the council of Constance, and Luther and Melancthon speak favorably of them. The flourishing period of the order was from 1400 to 1500, most of their houses being built between 1425 and 1451; they had in all from 30 to 50 establishments. By the middle of the 17th century the order became extinct, some of the brethren becoming Protestants, while some were absorbed by the Jesuits and other Roman Catholic orders. This order is frequently confounded with the Beguins and Lollards.

BRETHREN AND SISTERS OF THE FREE SPIRIT, or Spiritualists. See BEGHARDS.

BRETHREN OF THE CHRISTIAN SCHOOLS, an order established at Rheims by the abbé de La Salle in 1679, and sanctioned by Benedict XIII. in 1725, six years after the death of the founder. The object of the order was to provide instruction for the poorer classes. The members take upon themselves the vows of chastity, poverty, and obedience. These vows are first taken for three years only, and then renewed for life by those who desire to remain in the order. Their costume is a coarse black cassock, and a small collar or band around the neck, for the house, and a hooded cloak and a wide hat for outdoor purposes. Their diet is of the simplest kind. Their teaching is mainly rudimentary, although in some of their schools Latin and the higher mathematics form part of the course. Priests may be admitted to the order, but no member may become a priest, and lest they should aspire to that dignity, the brethren are forbidden to study Latin until reaching the age of 30. In 1688 the order was introduced into Paris. In 1792 they refused to take the oath to the civil constitution, and were driven from their houses and debarred the exercise of their functions. At the peace of 1801 they returned to their schools, and soon spread themselves again over France, whence they extended into Italy, Corsica, Cayenne, Belgium, and Algiers. In 1830, in the revolution of July, the persecution which fell upon the Jesuits also visited them. The aid of government was withdrawn. At that epoch they opened evening schools for adults, wherein they received and taught mechanics and laborers who had no time to devote to learning in the day. The chief house of the congregation is at Paris, rue Oudinot, and has generally from 400 to 500 brethren. In 1868 the congregation had upward of 10,000 brethren, and instructed in France alone more than 300,000 pupils. In the United States in the same year 323 brethren instructed about 15,000 pupils. Besides the Brethren of the Christian Schools founded by La Salle, there are a number of other

Roman Catholic congregations devoted to the cause of education. (See SCHOOL BROTHERS AND SISTERS, CONGREGATIONS OF.)

BRETHREN OF THE HOLY TRINITY, a society founded in France near the close of the 12th century, whose members pledged themselves to give a third part of their revenues to procuring the redemption of Christians who had fallen captive to the infidels, and were in Mohammedan slavery. It was established by John of Matha and Félix de Valois.

BRETON, Jules Adolphe, a French painter, born at Courrières. He excels in pictures of rural life and scenery. He began to exhibit about 1855, and in 1859 and 1861 received medals of the first class for landscapes. Among his best works are "The Gleaners," "Blessing the Grain," "Evening," "The Weeders," and "The Turkey Keeper."

BRETON LANGUAGE AND LITERATURE. See CELTIC LANGUAGES AND LITERATURE.

BRETON DE LOS HERREROS, Manuel, a Spanish poet, born at Quel, Old Castile, Dec. 19, 1800. He was a volunteer in the army, and held civil offices at various times, but owing to his liberal politics he was not permanently employed. His comedy, *A la vez viruelas*, composed in 1817, was successfully performed in 1824; and he became the author of upward of 150 plays, original or remodelled from old Spanish comedies, or taken from the French and Italian. His recent dramas have been modelled after the early dramatic school of Spain. Several of his plays were performed in Paris in 1847, and one of them was translated into French under the title of *Le poil de la prairie*. He excels also as a humorous and satirical poet. A collection of his poems was published in 1850-'52 (5 vols., Madrid). He is a member of the royal academy of Madrid.

BRETSCHNEIDER, Karl Gottlieb, a German theologian, born at Gersdorf, Feb. 11, 1776, died in Gotha, Jan. 22, 1848. He became general superintendent at Gotha in 1816, and was appointed superior councillor of the consistory in 1840. His religious works are very numerous. Among the most important are: *Systematische Entwicklung aller in der Dogmatik vorkommenden Begriffe* (1805; 4th ed., 1841), and *Handbuch der Dogmatik der evangelisch-lutherischen Kirche* (1814-'18; 4th ed., 1838). He commenced, under the title of *Corpus Reformatorum*, a collection of the writings of the German reformers, which was continued after his death by Bindseil (28 vols., 1834-'60). He also wrote religious novels: *Heinrich und Antonio* (1826), *Der Freiherr von Sandau* (1829), and *Clementine* (1841). His autobiography was published in 1852.

BREUGHEL, I. Pieter, the first of a celebrated family of Dutch and Flemish painters, born near Breda about 1520, died in Brussels about 1580. He studied with Peter Koeck, travelled through portions of France, Italy, and Switzerland, making sketches, and went to reside at Antwerp, where he was made a member of the

academy in 1551. He painted village festivals, attacks of banditti in wild landscapes, or scenes among the gypsies. **II. Pieter** the younger, son of the preceding, called "Hell Breughel," from the diabolical character of his subjects, born about 1567, died in 1625. His pictures generally represent scenes in which devils, witches, sorcerers, or robbers play a conspicuous part. One of his most famous works is the "Temptation of St. Anthony." **III. Jan**, brother of the preceding, commonly known as "Velvet Breughel," either from his habit of dressing his figures in velvet, or from the softness and delicacy with which he painted flowers, born at Brussels about 1570, died about 1635. His first pictures were miniatures and fruit and flower pieces; but after a tour through Italy he took to painting landscapes, which are remarkable for exquisite finish, and the spirit and character of the minute figures introduced into them. He returned to Flanders with so great a reputation as a landscape painter, that artists frequently applied to him to paint backgrounds and other accessories to their pictures. In this way he assisted Rubens in the celebrated pictures of "Adam and Eve in Paradise," "The Four Elements," and "Vertumnus and Pomona."

BREVARD, a S. E. county of Florida, bounded E. by the Atlantic ocean; area, about 5,600 sq. m.; pop. in 1870, 1,216, of whom 19 were colored. The surface is low and flat and dotted with lakes. The Kissimee river intersects the W. part, and empties into Lake Okeechobee, on its S. W. border. Low sand islands lie along the coast, between which and the mainland is a narrow sound called Indian river. The chief productions in 1870 were 88,650 bushels of Indian corn, 4,000 of peas and beans, 38,700 of sweet potatoes, and 6,450 lbs. of rice. There were 191 horses, 149 mules and asses, 69,390 cattle, and 4,550 swine.

BREVIARY, a book containing the "canonical hours" or "divine office" which the Roman Catholic clergy and monastics are obliged to recite every day, and which was formerly said by the laity likewise. The name, derived from the Latin *breviarium*, *brevia*, is supposed to have been given because the office now in use is an abridgment of one much longer. The origin of the breviary was different in different parts of the church. Thus the diocese of Antioch is said to have received it from Diodorus or Flavian, that of Constantinople from St. John Chrysostom, and that of Milan from St. Ambrose. Rome obtained it probably from Pope Gelasius I., in 494, and the churches of Spain from St. Leander, bishop of Seville about 620. These office books differed greatly both from one another and from the Roman breviary of the present day. In the course of time they became filled with legends of the saints of very doubtful authenticity, and many reforms were attempted, but without much success until Pope Pius V. and the council of Trent established a uniform office for the whole

church. This was subsequently corrected by Clement VIII. and Urban VIII., and is the one now in use. Before the council of Trent, however, Cardinal Quignon had published in France an expurgated and amended breviary, which, though condemned by the Parisian faculty of theology, was approved by Julius III. and Paul IV., passed through several editions, and for many years was generally used by the French clergy. In the Greek church, the office book is called *τάξις* (order), *ὁρολόγιον* (dial), or *εὐχολόγιον* (collection of prayers). It is very nearly the same in all the monasteries and churches, and is divided into two parts, one containing the morning, the other the evening office. The psalter is in 20 divisions, called *καθίσματα* (sittings), because a rest or pause is made after each one. The Armenians and other nations have similar breviaries.

BREWING, the manufacture of beer. The process consists in producing a saccharine extract from barley or other grain, adding to this hops for flavoring and preserving, and causing it to undergo the vinous fermentation. Water, composing as it does about 88 parts in 100 of beer, is an important ingredient, and great attention should be paid to its selection. The freer it is from all decaying and impure matters the better, not only as far as the quality of the product is concerned, but also its quantity, for the elimination of the impurities has been found to involve a loss. There is a difference of opinion as to whether hard or soft water is better for brewing. The celebrated English ales, Allsop's, Bass's, and Salt and co.'s, are made with very hard water containing large quantities of earthy sulphates. The brewers of Bavarian beer, however, prefer either soft water, or that which contains less mineral matter. Although grains and other substances are used in making beer, barley has been found to be the most suitable, being the most easily managed, and furnishing the best beer. There are two species of the grain in this country, *hordeum vulgare* and *hordeum distichum*, the former having four and the latter two rows of seeds in the head. Besides these there is a third species, cultivated in Europe, called *hordeum hexastichum* or six-rowed barley, known in Scotland by the name of bigg, a hardy plant, well adapted to cultivation in that country. The two-rowed yields the larger and heavier grain. The common four-rowed barley of this country is preferred by the maltsters of the United States and Canada. It has a thinner husk, contains a larger proportion of starch, and is said to make the best wort. The hop, the female catkin of *humulus lupulus*, gives the principal flavor, and also aids in clarifying the liquor by the removal of albuminous matter. The various parts of the catkin are the scales, nuts, and lupuline grains, the last being of most importance, but the other parts are all valuable. As the lupuline grains contain about two per cent. of volatile oil, it is important to have the hops well pressed at the

time of gathering. They should have a uniform golden yellow color, and when rubbed in the hands should make a yellow stain and yield a strong odor.—The art of brewing may be divided into—1, malting; 2, preparing the wort; 3, fermenting; 4, clarifying. Malting consists of three distinct stages: 1, steeping; 2, couching, sweating, and flooring; 3, kiln-drying. In making malt great attention must be given to the temperature of the air. It cannot be carried on in hot weather, so that the work of the maltster is confined to the autumn, winter, and spring months. The steeping, which has for its object the expanding of the grain with water to prepare it for germination, is performed in large cisterns of wood, stone, or cement. Water of ordinary temperature is turned in to a certain height, and as much barley is introduced as, when levelled, will allow the water to cover it to a depth of six inches. The steeping generally lasts from 50 to 65 hours. Too long a time is injurious, interfering with the germination and causing waste. The process is completed when the grain may be easily pierced with a needle or easily bent. Some maltsters carry the process further than others, and prefer to have the grain soft enough to be mashed between the fingers. If it is continued too long, so that the contents have become milky, the barley is spoiled for malting; it has lost the capacity to germinate. Barley imbibes about 50 per cent. of its weight of water in the process of steeping, and increases in bulk about 20 per cent. It is well to wash it several times while steeping with fresh water. This causes no waste, prevents souring, and therefore promotes the uniform germination of the seed. After the steeping has been carried to the proper point, the water has to be drawn off and the barley placed upon the couching floor, which is usually constructed of stone or cement. The temperature of the room should be between 50° and 55° F., to allow the maltster to have the best control of the process. Still, the process can be conducted with fair results until it reaches 60°. When it rises above that temperature malting should be discontinued. When taken from the steep the malt is placed upon the floor in beds about 18 inches high, and far enough apart to allow of the necessary spreading afterward, and there allowed to lie for 12 hours, when it is turned over, but without being spread. In 12 hours after this, or 24 after removal from the steep, the grain has attained its greatest bulk. The kernels are no longer wet on the surface, and to the touch feel almost dry. The couch, however, soon begins to grow warm, and gradually increases in temperature, until at about the end of the second day it has reached 60° or 65° F. It gives off an agreeable fruity odor resembling that of apples, and a dew appears upon the surface of the grain. This is the sweating stage, during which the germination commences. The fibrils of the radicle sprout from the tips of the ker-

nels, and a white elevation is formed which separates into three or more radicles. About 24 hours after this, generally toward the end of the third day, the plumula, called the acrospire, appears at the same point, and turns back under the husk, toward the other end of the seed, and would there issue as a green leaf if its growth were not arrested. Consequently the couch is spread out till it is not more than eight or ten inches deep. The temperature, however, continues to rise until the end of the fourth day, varying somewhat, according to circumstances, until it has reached 80° F. This is thought by the best maltsters in this country to be the limit to which it should be allowed to go; and they keep the grain at this temperature until the sprouting has proceeded almost far enough. Then the beds are spread still further, with great care. This is a critical time, and requires much judgment on the part of the maltster. The acrospire has now very nearly reached the other end of the seed, and the transformation of the starch has been carried as far as desirable. The barley, or malt, as it may now be termed, is carefully turned over two or three times a day, being spread more at each turning, until at the end of the process the depth is only three or four inches. This constitutes the flooring, as it is technically termed; but the couching, sweating, and flooring are only different stages of the same process. The temperature at the last spreading is said to be in England about 62° F., and in Scotland, five or six degrees lower. In this country careful maltsters keep the temperature near 70° till very near the close, alleging that by not too suddenly checking the growth of the sprout they secure more uniform development. The couching and flooring occupy about two weeks in England, and in Scotland a somewhat longer time. In this country the grain is usually kept on the floor about nine days in the most favorable weather, and in the spring and fall sometimes only seven or eight days. It is the object of some maltsters to convert as much of the starch as possible into sugar, while others rely upon accomplishing this in the kiln, and in the succeeding operations of the brewer. While the acrospire has been growing a wonderful transformation has been going on within the seed. The contents have become whiter, and crumble between the thumb and finger like meal. The albumen has disappeared and the gluten has diminished in quantity. About half of the starch remains unchanged, but the other half has been converted into dextrine and grape sugar. If the germination continued, the roots and stem would appropriate these substances in their growth. The unchanged starch is not lost, but is converted into sugar in succeeding processes. How has this transformation been accomplished? At the commencement of germination, in malting, as well as when a seed is placed in the earth, a substance is formed at the base of the sprout by a change which has taken place in the albu-

men in consequence of the influence of the vitalizing principle in the germ, which has been awakened under the influence of heat and moisture. This substance is called diastase, and possesses the power at ordinary temperatures of converting starch into dextrine and grape sugar. This transformation can also be effected by gluten, but it requires a longer time. In malting, if the germination is allowed to proceed until the rootlets and stem attain a certain size, it will be found on examination that all the starch, sugar, and gluten have disappeared; the starch having passed into the soluble condition of sugar, and, together with the gluten, having been appropriated by the growing stem and fibrils. The object of the maltster in causing germination is, through the action of diastase, to convert the starch of the grain into dextrine and grape sugar, which is the natural sugar of vinous fermentation. When the greatest amount of dextrine and sugar has been produced, with the least loss in the growth of the rootlets and plumula (acrospire), the operation is arrested by subjecting the malt to the heat and dry air of the kiln. The malt kiln is a chamber having a floor made of sheet iron, perforated with numerous holes sufficiently small to prevent the grain from falling through. This floor is heated by an ascending current of hot air, by means of a furnace below, which not only warms the iron floor, but passes up through the malt, warming and drying it at the same time. The malt should be spread upon the floor about five or six inches deep and raised to a temperature of 80° F., the heat gradually increasing until at the end of the operation it has reached 180° or sometimes 140°. The malt is to be turned over about every three hours, until toward the close, when, the heat increasing, it should be turned every hour, to secure even drying and even color. Kiln-drying usually takes two days, including the time occupied in placing the malt in the kiln and removing it. It is then taken to another apartment and spread out, or it may be put in heaps and further manipulated and improved in color. When it is desired to make beer of a deep color, the heat of the kiln is increased. For the brewing of porter, a portion of the malt is almost charred, or the whole of it may be made of a deeper color. When taken from the kiln the grain has lost about 20 per cent. of its weight before steeping; but as the raw grain would have lost by the same degree of drying 12 per cent., the loss occasioned by malting is only about 8 per cent. The kiln not only dries the grain and prevents the further growth of the rootlets and acrospire, and thereby the loss of sugar, but also serves to convert a considerable portion of the unchanged starch into dextrine. Good malt is plump, sweet to the taste, has a pleasant odor, breaks easily between the teeth, and is full of soft flour. Barley of one grade and age only should be used at one steeping, as new barley germinates more quickly than old. After kiln-drying, the

radicles, which have become brittle and have fallen off, are separated by a wire sieve.—The preparation of the wort is the next process in the art of brewing. Ordinarily the brewer commences here, because he generally buys his malt of the maltster. The process consists of three different stages: 1, mashing, or the extraction of the saccharine material from the malt; 2, boiling the wort and adding the hops; 3, cooling. The mashing is performed in a vessel called the mash tun, which is a large tub from six to eight feet in height and from twelve to fifteen feet in diameter, and capable of containing from 100 to 300 barrels. It is made of wood and bound with iron hoops, like an ordinary tub, which it resembles, except that it is usually larger at the bottom than at the top. It is furnished with machinery for stirring the mash, and has a double bottom, the upper one, which is from five to ten inches above the lower, being perforated with small holes to allow the wort to pass through. Mashing has for its object the conversion of the unchanged starch left in the malt into dextrine and grape sugar, and the extraction of it, together with the dextrine and sugar already formed in the malting, and also of the gluten which remains, by means of water at a suitable temperature; thus forming a solution which is called unhopped wort. An important agent in effecting this is the diastase which was produced during germination, and which still remains in the malt. To appreciate the nature of the operation, it is necessary to be acquainted with the following facts: The dextrine, or starch gum, which is the first product of the action of malt upon starch, may be preserved in that state, or still further changed into grape sugar, according to the temperature at which the mixture is digested. If we take eight or ten parts of malt and stir it in about 400 parts of water at 80° F., then raise it to 140° and stir in about 100 parts of starch, and then further increase the temperature to 158°, and maintain it between that and 167° for about half an hour, the milky, pasty solution becomes fluid and transparent. The starch is converted into dextrine, and if the solution is now raised to the boiling point and evaporated, the dextrine will be obtained in the form of a viscid gum, which is used in the arts under the names of starch gum and British gum, although it is prepared by another process. The raising the temperature of the solution to the boiling point has deprived the diastase of its peculiar property of transforming dextrine into sugar. If, however, the temperature had been kept between 158° and 167° for two or three hours, the dextrine would have been converted into sugar by the continuance of the saccharine fermentation, of which the transformation of starch into dextrine is a part. This is what takes place during the process of mashing, and explains why it is performed at a certain temperature, and why great care ought to be taken that the water is not too hot when turned upon the malt.

Mashing is usually performed in the following manner: Water, at a temperature of 160° to 165° F., is introduced into the tun beneath the false bottom, while at the same time malt which has been crushed between iron rollers is poured in at the top. The proportion of malt and water used in the preparation of wort for beer of ordinary strength, is about one quarter of malt (352 lbs.) to 220 gallons of water, or in the proportion of 1 to 5 by weight. This will yield a wort having a specific gravity of about 1.06, and containing about 14.66 parts of malt extract in 100 parts of liquid. Strong beers, like Burton and India ales, are made from a heavier wort, while schenkier, or draught lager, and other light kinds are made from lighter worts. At the commencement of the mash all the malt is run into the tun at once; if it were not, there would be a difference in time at which different portions would be acted upon, and there would be in other respects interferences with the proper conduct of the process. The water is not all let in at one time. At first enough is added to the malt to allow of thorough mixing by the revolving paddles, or agitators, which move around in the tun. After standing fifteen or twenty minutes more water at the same temperature, or perhaps two or three degrees higher, according to the judgment of the brewer, is turned in, using altogether for the first setting a little less than one half of the whole quantity to be used in the brewing. The mash is again thoroughly stirred and allowed to stand about two and a half hours. Those brewers who do not care to have the starch mostly converted into dextrine and grape sugar during the first setting do not let the mash stand quite so long; but it is generally considered better to have the transformation well advanced during the first setting. The wort, as the liquid extract is called, is now drawn off into an underback (lower vessel), from which it is afterward pumped into the boiler. The underback is frequently dispensed with in modern breweries, and the wort is drawn immediately from the mash tun into the steam boiler which is now preferred to the old copper boiler, with a fire under it. When the wort is run into the boiler it receives its proper allowance of hops. This prevents the occurrence of changes which might interfere with the fermentation, and prevent the beer from attaining its finest quality. The wort, when drawn off, should be transparent and about the color of the malt from which it is extracted. Turbidity indicates that it contains unaltered starch, which would cause the beer to become sour. This danger furnishes an argument in favor of allowing full time for the first setting. A little more than half of the water which remains to be added is now introduced at a temperature of 167° into the tun, stirred with the remaining malt, and allowed to stand from half an hour to fifty minutes. It is then drawn off into the underback, or directly into the steam boiler as

the case may be, and the requisite quantity of hops is added. The remainder of the water is then run into the mash tun at the same, or perhaps a little higher temperature, and the mash stirred and allowed to stand about half an hour. The wort, which has little strength, is then drawn off, and when introduced into the boiler the remainder of the hops is turned in also. The boiling, which has been going on for an hour or more, is continued two and a half or three hours longer. The quantity of hops that should be added varies with the kind of beer which is brewed. In making stock ale, from five to eight pounds, but for the lighter ales and for lager and schenkier, from two to three pounds to the barrel are used. The addition of hops to the wort is an operation about which there is a variety of opinions. Some suppose that the hop is merely added to flavor the beer, but it possesses quite as much value in preserving the beer as it does in flavoring it. The tannin contained in the scales aids in clarifying the wort, by combining with the albuminous matter that may have remained undecomposed. The other principles also, as the lupuline and the odorant oil, exert an influence during the cooling process in checking premature fermentation; and during fermentation the hop moderates the action in such a way as greatly to improve the quality of the beer. A perfectly satisfactory explanation of the manner in which the hop acts has not yet been given, nor has any substitute for it ever been found. The continued boiling of the hop being regarded as necessarily involving a great waste of the odorant principle, attempts have been made to extract its virtues and add them to the wort after it has been boiled; but thus far success has not attended the experiment. The flavor of the beer is good, and if it has been very carefully brewed from the best materials perhaps it has been improved, but its keeping qualities are inferior. Perhaps the addition of a little tannin to the wort during boiling might remedy the defect, but it is questionable, as the hop has other preserving qualities besides the tannin. It is found, moreover, that although in boiling hopped wort a strong odor is perceived, the loss is not as great as is often supposed. It has also been attempted to extract the virtues of the hop in the wort without bringing it to the boiling point, but this experiment has also been unsuccessful. Although the beer had a fine appearance and flavor, it would not keep as well as that made from boiled worts. In fact, the most practical brewers have found it necessary thus far to boil their worts, to arrive at satisfactory results. It is probable that the easily decomposed azotized matters cannot be with certainty eliminated in any other way without injury to the beer. The boiling is known to have continued long enough if the coagulated flocks are distinctly separated from the perfectly clear liquid in which they are suspended; or if they are found collected together in considerable

quantity at the bottom of the boiler. When the boiling is finished, the hopped wort is drawn off into another tun, called a hop back (hop vessel), which has a perforated false bottom, or strainer, for the purpose of retaining the hops. From the hop back the wort is pumped up into the coolers, which are placed in the upper story of the brewery. These coolers are wide, shallow pans, six or eight inches in depth and fifty or more feet square; they cause rapid cooling in consequence of the great amount of surface exposed to the cooler atmosphere and the great evaporation which takes place. In this country, however, this form of cooler is only used for cooling the wort of lagerbier; an apparatus called a refrigerator being used to cool the wort of ale or strong beer. This is not fermented at so low a temperature as lagerbier is, and the necessary cooling can be performed with much greater facility by means of the refrigerator, which is simply a coil or layer of pipe through which a stream of cold water may be made to pass with any required rapidity. A form of hydrometer called a saccharometer is used to measure the degree of concentration of the worts while they are passing through the various stages of preparation. When the wort reaches the cooler or the refrigerator it usually has a temperature of about 200° or more, according to the rapidity with which it has been pumped. It is desirable to have it cool as quickly as possible, so that no premature fermentation may take place before the yeast is added in the fermenting tun. Wort which is to be subjected to the ordinary top or rapid fermentation should be brought to a temperature of 60° or 63°. As soon as it is run into the fermenting tun, yeast is added to induce the vinous fermentation. The quantity used depends upon the extent to which it is desired to carry the fermentation, and also upon the amount of saccharine matter in the wort. For the fermentation of Bavarian beer much less is used, and that of a different kind, than for the ordinary English ale. For the stronger kind about one gallon of yeast is used in fermenting 100 gallons of wort, but for lighter ales one part to 150 or 200 is sufficient. The yeast is taken from the last preceding fermentation, and should have been produced from similar beer. It is generally prepared a short time before using by mixing it with a portion of wort and putting it in a warm place till it begins to ferment. This mixture, which is called lobb, is then stirred into the wort. Too much yeast will cause excessive action, consume too much of the sugar, and make the process more unmanageable. The principal constituents of the wort, or gyle (as it is termed by the English brewers after reaching the fermenting tun), are grape sugar, dextrine which has not yet passed into sugar, gluten, lupuline (the bitter principle of the hop), and other odorant principles. The brewer's problem now is, to produce in this infusion, from the elements it contains, a certain quantity of alcohol

and carbonic acid, and to bring the liquor to a palatable condition, and one in which it may be preserved for use. The yeast is added to convert the dextrine into grape sugar, and this into alcohol. No part of the process of brewing requires such careful attention as the fermentation. A certain degree of imperfection in the wort may be remedied to a large extent by skilful fermentation; but an error in the latter process cannot be corrected. In a space of time varying from six to twelve hours, depending upon the condition of the yeast and the temperature of the wort and of the surrounding air, the fermentation commences, and a foam rises in little hillocks to the surface. This foam, which is composed of yeast, gluten, and sugar, made into fine bubbles by carbonic acid gas, appears in this form because the bubbles of acid ascend in separate columns, which are maintained by the motion which has been established in the liquid. The foam becomes thicker toward the middle of the tun, where it is thickest and rises to the height of two feet or more. After a time the color of the top changes to a light brown, probably the result of oxidation. The fermentation is generally better when this appearance is slight. The disengagement of gas is in proportion to the quantity of sugar converted into alcohol, and the temperature rises correspondingly, or would rise if it were not repressed by passing cold water through a coil of pipe placed in the tun; this is called the attemperator, and may be used for either lowering or raising the temperature. After a time, varying from 24 to 36 hours, the head of yeasty froth falls, and the newly formed yeast becomes more viscid, and the fermentation much less active. If it were allowed to proceed without the removal of this yeast, much of it would be precipitated, and, continuing to act upon the remaining sugar, would in time convert all of it into alcohol, and finally into acetic acid. It is therefore removed by skimming, and in the best breweries the liquid, or gyle, is drawn off into a second fermenting tub, or stillion, as it is sometimes called, and the fermentation allowed to proceed there until the process is completed. Here perfect yeast, formed from the gluten still remaining in the wort, rises to the surface, as a tough, partially organized scum, which is used in the fermentation of the succeeding brewing. The process for strong stock ale is continued for six or eight days, but for lighter ales, such as are called "present use," the time occupied is only four or five days. During the fermentation, from the diminution of the quantity of sugar and the production of alcohol, the fluid becomes thinner, and its specific gravity less; hence the fermenting process is also called by brewers the attenuation. The temperature rises during the fermentation, so that it may reach 80° or more; but the more careful brewers, except for special reasons, repress it, and endeavor to keep it below 70°. In Scotland the fermentation is often conducted at a temperature below 60°,

and the process prolonged considerably, occupying from ten days to a fortnight. In some breweries an apparatus is attached to the second fermenting tubs, or stillions, by which the yeast is carried off as fast as it forms. In others, however, it is allowed to remain floating upon the surface of the beer until the latter is drawn off. When the fermentation has perfectly converted the gyle into beer, it is drawn off into casks, for storage or for sale. This is sometimes done by running it into a third tun, called a racking tub, from which, after standing a short time, it is drawn off into the casks. These are then immediately bunged up and kept at a temperature of from 60° to 64°. The lighter ales may be drawn for use in three or four days after casking, but the stock ales are stored for six or more months. The temperature at which wort is fermented produces not only a difference in the products, but also in the mode in which the process is carried on. The conversion of sugar into alcohol and carbonic acid proceeds very slowly at a temperature as low as 45°; but the conversion of soluble gluten into insoluble ferment, when acted upon by a like ferment in the presence of air at such a temperature, is effected with facility.—The problem solved in the fermentation of Bavarian beer is the elimination of the gluten and other azotized matters that may be present, without the conversion of all the sugar into alcohol and carbonic acid, or the conversion of alcohol into acetic acid, and leaving the beer in a condition in which the sugar and alcohol are not liable to further change from exposure to the air. This is effected by a peculiar kind of fermentation, in which the yeast does not form upon the surface of the wort, but falls to the bottom, where it undergoes but little further change, thus leaving the surface of the liquid freely exposed to the air, by the action of which the soluble gluten becomes oxidized and transformed into insoluble yeast. The reason that ordinary yeast remains upon the surface of the wort is that it is held there by bubbles of carbonic acid, which is generated in great quantity in rapid fermentation. The yeast of slow fermentation falls to the bottom because the carbonic acid, disengaged from the slowly decomposing sugar, ascends in bubbles too minute to give sufficient buoyancy. The reduction of temperature allows the oxidation of the gluten to proceed more rapidly than the conversion of the sugar into alcohol and carbonic acid, so that before all the sugar is consumed the gluten is eliminated and has fallen to the bottom, where it possesses but little power, especially at the low temperature at which the wort is kept. This low temperature also prevents the alcohol from passing into acetic acid. If, after all the gluten is thus rendered insoluble and deposited at the bottom of the vessel, the beer is drawn off, it no longer contains any substance which is capable of being converted by oxidation into a ferment, and therefore possesses the quality of keeping a long time without becoming sour.

In the ordinary process of fermentation, in which the yeast rises to and remains at the surface, the gluten is not all rendered insoluble, but some of it remains in the beer, and on exposure to the air absorbs oxygen, and produces a ferment by which the remaining sugar is transformed into alcohol and carbonic acid, and the alcohol, again, into vinegar. The fermentation of Bavarian beer occupies a much longer time than that of common ale. The latter, as we have seen, occupies only six or eight days, while the other requires from four to six weeks, or even longer. The wort, which is prepared very much in the same manner as for other beers, is pumped from the hop back into the shallow coolers in the upper story of the brewery, and is reduced, either in them or by afterward passing it over the refrigerator, to about 45° F., as speedily as possible. It then passes into the fermenting tuns, which are placed in cool rooms or cellars having a temperature of 40° to 45°. The yeast is stirred into the wort, and in the course of two or three days the fermentation commences with the appearance of very minute bubbles of carbonic acid gas, which ascend and carry some of the yeast and the gluten to the surface, but do not retain it there; for the gluten absorbs oxygen from the air, and the insoluble ferment which it forms is deposited at the bottom of the tun as a viscous sediment, leaving the surface of the liquid exposed to the action of the air. The gluten is thus converted into yeast by atmospheric oxidation, and in time is entirely removed without the decomposition of all the sugar. Only as much has been transformed into alcohol and carbonic acid as it is desirable to have the beer contain. This kind of fermentation is called *Untergährung*, or bottom fermentation, and the yeast, which differs from common yeast, is called *Unterhefe*, or bottom yeast. Ordinary fermentation, in which the yeast forms upon the surface of the wort, is called *Obergährung*, or top fermentation, and the yeast thus formed, *Oberhefe*, or top yeast, and, according to Liebig, is in a state of putrefaction, while bottom yeast is in a state of eremacausis, or decay. The precipitated yeast has not the capacity of exciting ordinary fermentation, but ordinary yeast may be employed in exciting slow fermentation at a low temperature, which causes a yeast to be deposited at the bottom which, by being used a few times, may be converted into the yeast of bottom fermentation. After the beer has been fermented sufficiently it is drawn off into large casks and allowed to lie for several months in cellars or cool rooms, which are kept at a temperature of between 40° and 45° F. A very slight fermentation and fining process here continues, until at last the beer is perfectly transparent and free from all fermentable matter. On account of this treatment it is called *Lagerbier*. Many of the modern lagerbier breweries now use enormous quantities of ice to cool the rooms in which the beer is fermented and stored. These rooms may be so constructed that the temper-

ature can be perfectly controlled; and as the air retains no more moisture than it does in a cellar, it being generally near the dew point in either case, the ice-cooled rooms are liked by those who use them, particularly as the brewing can be conveniently carried on during the summer months. Manufactured grape sugar is now used by many of the lagerbier brewers to furnish an excess of material for the production of alcohol, thus allowing a smaller percentage of gluten in the wort. As the gluten in the Bavarian process is the chief substance to be eliminated, this practice allows the fermentation to be completed in a shorter time than when malt only is used. When the grape sugar contains no acid or other objectionable matters, the practice results in economy, but only on account of the saving of time, as the price of the manufactured sugar is fully equal to the cost of producing it in the wort from malt.—*Adulterations.* A few years ago ale drinkers were alarmed by a report that strychnine was used in the manufacture of ale. Dr. Ure gives the following reasons for considering this report groundless: "1. Strychnine is an exceedingly costly article. 2. It has a most unpleasant metallic bitter taste. 3. It is a notorious poison, and its use in any brewery would ruin the reputation of the brewer. 4. It cannot be introduced into an ordinary beer brewed with hops, because it is entirely precipitated by infusions of that wholesome, fragrant herb. In fact, the quercitannic acid of hops is incompatible with strychnia and all its kindred alkaloids. Hence, hopped beer becomes in this respect a sanatory beverage, refusing to take up a particle of strychnia, and other noxious drugs of a like character." Mr. Herepath has given a test for the detection of picrotoxine, the active principle of the *cocculus Indicus*, which is based upon the property possessed by charcoal of separating it from its aqueous solution. An excess of acetate of lead is added to the beer to throw down the lupuline and other extractive matters, the excess of lead in the filtrate removed by sulphuretted hydrogen, and the excess of this gas removed by boiling. The solution is then evaporated to a sirup, and agitated with animal charcoal, which will absorb any picrotoxine that may be present. On cooling, the charcoal is collected on a filter, washed with a small quantity of water, and dried at 212° F. The charcoal is then boiled in pure alcohol, which being filtered will upon evaporation yield crystals of picrotoxine if the beer was adulterated with it. If the evaporation is slowly and carefully conducted, the picrotoxine will separate in well defined quadrilateral prisms, sometimes in needles, and, when the evaporation has been rapid, in beautiful plumose tufts. Picrotoxine is inodorous, intensely bitter, and neutral to vegetable colors; dissolves in 150 parts of cold, in 25 parts of boiling water, and in 3 parts of boiling alcohol of specific gravity 0.800. Picric acid, which is said to be used in the adulteration of beer, may

be detected by Rohl's test, which is exceedingly delicate, and consists in boiling unbleached sheep's wool in the suspected beer for eight or ten minutes, and then washing the wool. If picric acid is present to the amount of only one part in 125,000, the wool will have a decided canary color. Chalk is sometimes used to neutralize the acid of sour beer. It may be detected by finding more than the usual quantity of lime in the ash. Carbonate of soda is often added to summer beer in kegs, particularly to that which has not been sufficiently fermented, and is liable to become sour. Common salt is frequently used, and can be quite readily detected by the taste, and by the thirst it creates.

BREWSTER, Sir David, a Scottish physicist, born at Jedburgh, Dec. 11, 1781, died at Allerly, near Melrose, Feb. 10, 1868. He was educated at the university of Edinburgh, where his attention was early turned to natural science. In 1807 he received the degree of LL. D. from the university of Aberdeen for his acquirements in this department; and in the following year he projected "The Edinburgh Cyclopædia," of which he continued to be the editor until its completion in 1830. In the mean time he continued those special researches into the composition and influence of light which made him famous. For his papers for the royal society of London upon the polarization of light he received several medals, and in 1816 one of the prizes of the French institute for the two most important discoveries in physical science made during the two preceding years. In 1819, in conjunction with Prof. Jameson, he commenced the "Edinburgh Philosophical Journal," which he afterward conducted alone for 16 years under the title of the "Edinburgh Journal of Science." He was also for many years one of the editors of the "London, Edinburgh, and Dublin Philosophical Journal." From 1827 to 1833 he was engaged in investigating the best means of illuminating lighthouses. In 1830 he received the principal medal of the royal society of London for further discoveries in the polarization of light, and was knighted in the following year. He was chosen principal of St. Leonard's college, Aberdeen, in 1841, and in 1857 he was president of the British association for the advancement of science, of which he was one of the founders. In 1859 he was chosen one of the eight foreign associates of the institute of France, and principal and vice chancellor of the university of Edinburgh. For many years he contributed brilliant articles on scientific subjects to the "North British Review" and the "Popular Science Magazine." He made many improvements in the construction of the microscope and telescope, invented the kaleidoscope, brought the stereoscope into scientific and artistic use, introduced the Bude light, and demonstrated the utility of dioptric lenses and zones in lighthouse illumination. Sir David Brewster did more than any other man of his day to popularize the study of natural science. Besides his numerous contribu-

tions to periodicals and cyclopædias, and to the transactions of learned societies, he wrote "Treatise on Burning Instruments" (1812); "Life and Letters of Euler" (1823); "New System of Illumination for Lighthouses" (1827); "Treatise on Optics," "Letters on Natural Magic," and "Life of Sir Isaac Newton" (1831); "Martyrs of Science" (1841); "More Worlds than One" (1854); and "Memoirs of the Life, Writings, and Discoveries of Sir Isaac Newton" (1855).

BREWSTER, William, an elder of the Plymouth pilgrims, born at Scrooby, England, in 1560, died at Plymouth, Mass., April 16, 1644. He was educated at Cambridge, and entered the service of William Davison, ambassador in Holland, but presently retired to the north of England, where his attention was chiefly occupied by the interests of religion. He was one of the company who with Mr. Bradford attempted to escape to Holland, and were thrown into prison at Boston. Having obtained his liberty, he first assisted the poor of the society in their embarkation, and then followed them to Holland. Here he opened a school at Leyden for instruction in English, and also set up a printing press. He was chosen a ruling elder in the church at Leyden, and accompanied the emigrants to New England in 1620, where until 1629 the principal care of the church devolved upon him, though, as he was not an ordained minister, he could never be persuaded to administer the sacraments.

BREZNŌ BĀNYA. See BRIES.

BRIALMONT, Henri Alexis, a Belgian military writer, born at Venloo, May 25, 1821. He is the son of Gen. Laurent Mathieu Brialmont, ex-minister of war. In 1843 he left the military academy at Brussels with the rank of sub-lieutenant. He was employed as engineer in fortifying Diest and Antwerp. In 1847 he became connected with the ministry of war, attaining in 1861 the rank of major. His principal work is the *Considérations politiques et militaires sur la Belgique* (8 vols., Brussels, 1851-'2). His *Histoire du duc de Wellington* (3 vols., 1856-'7) is also a work of some importance.

BRIAN BORU, or *Boróilme* ("Brian of the tributes"), the most celebrated of native Irish kings, born about 927, slain at Clontarf on Good Friday, 1014. He was the son of Kennedy, king of Munster, and succeeded him in 978. His first exploits were against the Danes of Limerick and Waterford. He confined them within the limits of those cities, and made them pay tribute in pipes of wine. In 1002 he made himself *ard-righ*, or supreme monarch of Ireland, putting aside the legitimate families, the O'Neills and O'Melaghlin, and imposing upon the subordinate kings heavy tributes in cattle, hogs, iron, mantles, and wine. His palace was at Kincora, in county Clare, near the present town of Killaloe. He had also palaces at Tara and Cashel. He caused a road to be constructed round the coast of the whole kingdom. In the latter

part of his reign Maelmora, the king of Leinster, revolted and called in the Danes to his assistance. Brian Boru repulsed the allied Danes and Leinstermen at Clontarf, and died on the battlefield. His son Morrogh also fell in the same fight. The Danes never regained any independent position in Ireland after this defeat. An ordinance of his prescribed that every one should adopt as a surname the name of his father, and thenceforth surnames became permanent in Irish families.

BRIANÇON (anc. *Brigantium*), a fortified town of France, in Dauphiny, department of Hautes-Alpes, 35 m. N. E. of Gap; pop. in 1866, 3,579. It is at the junction of the two sources of the river Durance, and at the foot of Mont Genèvre, and is 4,285 ft. above the sea. It commands the principal pass to the Italian and Swiss frontiers, is a depot of military stores for the French Alps, and is surrounded with a triple line of ramparts. Seven forts whose cross-fires protect all the approaches to the town are connected with each other by subterranean passages cut in solid rock. The principal works

are on the left bank of the Clarée, which is crossed by a bridge of a single arch, 127 ft. in span and 179 ft. above the surface of the water. The position is considered impregnable. The most famous productions of Briançon are chalk and manna (the latter from larch trees, also called Venice turpentine); and scythes, sickles, nails, cutlery, copper ware, and hosiery are manufactured there. It was formerly capital of a district called Briançon-nais, which during the early part of the middle ages was almost independent, then successively annexed to Dauphiny and the crown of France, and at the beginning of the 18th century for some years in the possession of Savoy.

BRIANSK, a town of Russia, in the government and 70 m. W. N. W. of the city of Orel, on the right bank of the Desna; pop. in 1867, 13,881. The town has an imperial cannon foundery, arms manufactory, and arsenal, a convent and many churches, and carries on a brisk trade in grain, hemp, and linen.

BRIAREUS, a renowned giant of Greek mythology, said by Homer to have been called Briareus by the gods, but by men Ægeon. He was

the son of Cœlus and Terra, and brother of Gyges and Cottus, and had like them 100 arms and 50 heads. When the inferior deities conspired against Jupiter and endeavored to dethrone him, Briareus rendered effective aid to the father of the gods; but when Briareus himself rebelled, he was put in durance under Ætna, which belched forth fire and flame as often as the monster struggled in his dungeon.

BRIBERY, at common law, the offering or acceptance of any undue reward to or by any person whose office or ordinary employment relates to the administration of public justice, in order to influence his conduct in such office or employment, and incline him to act otherwise than as a strict and conscientious discharge of duty would require. It extends to the giving or receiving a reward to influence the action of a voter at parliamentary elections, or of a member of parliament, or a cabinet minister or member of the privy council, of a justice of the peace, or officer summoning jurors, or the jurors themselves; and the attempt, though not successful, is a misdemeanor. Formerly very loose notions prevailed in England regarding the acceptance of gifts by judges from the suitors before them; and Lord Chancellor Bacon could make no better apology for the receipt of a great number of such gifts by himself than that the practice was common. The severe punishment inflicted upon him put an end to the practice for a long time; but in the reigns of Charles II. and James II. there was a shameful venality of judges, which, however, terminated at the revolution of 1688, since which the integrity of the English bench has generally been above reproach. The conspicuous exception was that of Lord Chancellor Macclesfield, who was impeached and removed from office in 1725 for making sale of offices in his patronage, and conniving at an illegal use of moneys on deposit in his court. In 1865, also, Lord Chancellor Westbury found it necessary to resign because not able to defend his conduct in the bestowment of patronage. Bribery is also punishable in England under various statutes. By statute 11 Henry IV., all judges and officers of the king convicted of bribery are subject to forfeiture of treble the amount of the bribe, are punishable at the king's will, and to be discharged from his service for ever. The provisions against bribery at parliamentary and other elections are very minute and specific, but no law has yet been able to remedy what is now and has for a long time been a crying evil. It perhaps reached its climax in the time of Sir Robert Walpole, but the enormous sums of money now expended in the parliamentary contests are not consistent with purity in elections. By common parliamentary law bribery of or by a member is sufficient cause for expulsion.—The statutes of the United States prescribe punishments for the bribery of members of congress and other officers of government, and of jurors, and bribery in contracts. Bribery of a member of a legisla-

tive body, or an attempt to bribe a member, or a judge or juror, is also a contempt of the body or the court, and has sometimes been punished as such. In 1870 a member of congress was expelled for a corrupt distribution of his patronage, and another resigned on similar charges being made against him. The charge of corruption has seldom been made against judges of the highest courts in this country, and their integrity has generally been above suspicion. In the state of New York, however, charges of a very gross nature were made against two judges of the supreme court, which resulted in 1871-'2 in the resignation of one and the impeachment and condemnation of the other; a judge of the superior court in the city of New York was also tried by the senate and dismissed from office. The several states have statutes for the punishment of different classes of bribery, and the punishments range from a fine to imprisonment in the penitentiary.—For an account of parliamentary corruption in England, see May's "Constitutional History," chapter vi., and the numerous authorities there referred to.

BRICK, a building material made of clay, moulded commonly in rectangular blocks, and baked. The most ancient records make mention of their use. The early inhabitants of Babylonia found on the plain in the land of Shinar the clay for their construction, and "said one to another, Go to, let us make brick, and burn them thoroughly; and they had brick for stone, and slime had they for mortar." (Gen. xi. 3.) The slime was probably the semi-fluid bitumen used at early periods in Egypt and Babylonia as a cement; and no better building materials have ever since been used than those ancient bricks, and the natural mortar employed to bind them together. The walls of Babylon were built of burnt bricks laid in bitumen, as were the exterior walls of the still existing mounds, the largest of which is supposed to have been the tower of Babel. The interior of this mound is filled with unburnt bricks set in clay, with layers of reeds between every five or six courses. In other parts of the work the bricks were laid in lime mortar of exceeding toughness. From the frequent reference to the making of brick in the Old Testament, the manufacture appears to have been an important one with the Israelites and Egyptians. It was a principal task imposed by the latter upon their captives. The gathering of straw and stubble for mixing with the clay indicates that they were sun-dried, like those seen at this day in some of the pyramids of Egypt. Upon one of these, probably the brick pyramid of Howara, 10 leagues from Cairo, was formerly an inscription, cited by Herodotus, of which the following is a translation: "Do not undervalue me by comparing me with pyramids of stone. For I am better than they, as Jove exceeds the other deities. I am made of bricks from clay, brought up from the bottom of the lake adhering to poles." The same ma-

terial was used for other structures of high antiquity. The Greeks gave particular attention to having them perfectly adapted to the use to which they were to be applied; in some instances, as stated by Pliny, not allowing them to be used until after they had been seasoned five years, and had received the approval of a magistrate. The palaces of Croesus, king of Lydia, of Mausolus of Halicarnassus, and of many other Asiatic sovereigns, some of the temples of Athens, and the walls of that city looking toward Mount Hymettus, were built of this material. The Romans perfectly understood the art, as the bricks in the baths of Titus and Caracalla bear witness. The stone of the Colosseum has not proved so durable. In the ruins of their forts, walls, &c., in Great Britain, they are found of an excellent quality, of a deep red color, well burnt, and very hard. The brick made by their successors in England was not particularly noteworthy until about the middle of the 14th century. In the time of Henry VIII. and Queen Elizabeth so good an article was produced, that it was employed in the construction of many fine edifices. In modern times the manufacture is more remarkable for the immense scale upon which it is conducted, than for the good quality of the product—a fact attributed by English writers to the practice so generally adopted in London of building houses upon lands leased for a certain period, at the expiration of which the property reverts to the owner of the ground. The Dutch appear to have succeeded better than the English to the skill of the Romans. Their bricks have been famous from an early period for soundness and durability. So substantial were they, that they served well for the floors of houses, and even for street pavements. Specimens of Holland brick, brought over by the early settlers, are to be met with in some of the old Dutch houses of New York. Among the Asiatic nations the manufacture has continued at a high degree of excellence from the remotest periods. In the hilly country of Nepal bricks are made of such remarkably compact texture, and so elegantly ornamented upon their surface, as to be peculiarly fitted for architectural decorations. The Chinese give to the face of their brick the texture of porcelain. The ancient Peruvians excelled in the manufacture of brick, as in many other of the useful arts. Ulloa, after carefully examining the large bricks, was confident there must have been some secret in their composition, which was lost in his time, so superior were they to those made by any process then known. They are described by Prescott as large blocks or squares, made of a tenacious earth mixed up with reeds or tough grass.—The plastic nature of clay, and its property of hardening by heat into a substance like stone, are qualities so obviously adapting it for building purposes, that no people requiring permanent dwellings have failed to perceive them, and availed themselves of its use. But clay is not uniform in compo-

sition, and much of it requires some admixture of other substances. The purer aluminous earths consist of about two parts of silica to one of alumina, together with a larger or smaller proportion of water. They are remarkable for their plasticity, and mix freely with any quantity of water. But such materials, if moulded and baked, would shrink greatly and bend and warp; cracks would be produced from the outside hardening before the moisture of the interior could escape through the viscid mass. Such rich or fat clays require to be tempered with sand, or cinders and ashes, which render their texture more open, so that they retain their form; but they may without this tempering serve for baking into thin sheets as tiles. The quantity of sand or other substance required for any clay can only be determined by actual experiment. Some clays contain a proper proportion of sand naturally mixed with them. Others contain too much, and the bricks from these will fall to pieces. Admixture of fatter clays is the only method of making such useful, unless an expensive process be adopted of suspending the earth in water, and drawing off and collecting that which is held longest in suspension. Besides sandy clay or loam, calcareous clay or marl is sometimes used for the manufacture of brick; but if much lime be present, the compound may be too fusible to answer the purpose of making good brick. Oxide of iron is rarely absent. In the process of burning it is converted into the peroxide, and imparts to the whole brick its red color, more or less deep according to the degree of oxidation. The first of the following analyses is of a clay highly charged with oxide of iron, given in Knapp's "Chemical Technology;" it is largely used in the neighborhood of Glasgow, Scotland, for making brick; the quantity of water is less than is commonly given in the analyses of clay; the second is of a clay suitable for potters' use or the manufacture of brick:

	(1)	(2)
Silica.....	49.44	48.5
Alumina.....	84.26	83.2
Protoxide of iron.....	7.74	1.0
Lime.....	1.48	3.5
Water.....	1.94	18.0
Magnesia.....	5.14	Loss, 0.8
	100.00	100.00

The more free the clay is from other ingredients than silica and alumina, the better the bricks made from it withstand high temperatures. Clay taken freshly from its bed, even if of suitable composition, is not in a condition to be at once moulded into brick. It must first be exposed to the weather until its particles are disintegrated, when it can be kneaded into a mass of uniform consistency. This is best effected by the action of frost, the water diffused through the substance expanding by freezing and breaking it in every direction. The longer the exposure is continued, the more effectually is the clay reduced. This is followed by covering the clay with water and leaving it for

a short time in a pit or tank. The kneading was formerly conducted by treading of horses, oxen, or men, and the work was no doubt more efficiently done by the naked feet of men than by the machinery afterward introduced for this purpose; for the lumps, stones, sticks, &c., mixed with the clay were thus readily detected and removed. The pug-mill is the first form of machinery introduced for grinding the clay. It is a conical or cylindrical tub, standing on end, with a shaft passing vertically through it, armed with blades, which cut and knead the clay delivered in the top, forcing it down by their oblique position to the line of the shaft, as this is carried round by a horse attached to a horizontal arm. The clay thus ground and kneaded continually passes through an opening in the bottom of the mill, and is then cut into convenient pieces and stacked away for use. It must then be handled again for moulding it, and the practice was formerly to forcibly throw a quantity into the mould, which was a box of wood or of brass without top or bottom, and then strike off what was superfluous. The mould is always sanded to prevent the clay adhering to it. A box containing a row of five or seven moulds open at bottom was afterward contrived to run in under the lower part of the pug-mill and receive the clay, the further exit of which was at the same time arrested until another box of moulds replaced the one just removed. The work was thus rendered more expeditious with less expenditure of labor. In whatever way the kneading is conducted, especial care is taken to separate from the clay roots, sticks, and pebbles, the presence of which in the bricks would disfigure and weaken them. Even if the stones were buried in the interior of the bricks, a cavity would be left around them, for the reason that the stones first expand while the clay contracts by heating, and afterward contract by cooling in a much greater degree than the clay. In tempering the clay, it was found highly advantageous at the great brick yards near London to introduce a portion of coal ashes, which always contain more or less fine coal. The use of fine anthracite was introduced for the same purpose at the kilns on the Hudson river in 1838, and has been found so serviceable that it has been ever since continued. The quantity employed is about 75 bushels to 100,000 bricks. It is thoroughly intermixed in the kneading, and has the effect of saving a portion of the fuel, while it diminishes the time of burning; the quality of the bricks, however, is not so good as of those made in the old way. For drying the bricks previous to baking, the first requisite is a smooth level yard fully exposed to the rays of the sun, or, if covered by a roof, open to a free circulation of air all around. To this the moulds containing the bricks are brought, and, being placed upon the ground, are cautiously lifted off, leaving the bricks behind. They are arranged in rows, and in case of rain, if not under a roof, must be

covered with boards, as they are in danger of being washed away. The drying should be thorough, or the bricks will be likely to crack in baking. After depositing the bricks on the drying floor, the moulds are taken back, are dipped in water, and then into sand, and are ready to be refilled. When well dried the bricks are removed to be baked. This is effected in England sometimes in permanent kilns, which hold as many as 20,000 bricks, and are filled and emptied like those for baking earthen ware, the burning being completed in about 48 hours. The method in common use in this country of piling the green bricks upon one another to make their own kiln is also adopted there; but the arrangement is called a clamp instead of a kiln. By this method half a million bricks, or even a million, are burned in one operation. A central double wall is built lengthwise along the kiln, its lower portion of bricks already baked, and on each side are parallel longitudinal fire flues built of unburnt brick, laid very open; over them the great body of brick is piled after an exact system, vertical flues ascending to the top, and the whole work being laid in an open manner for the free circulation of the gases. The fires are made in one end of the flues, and the heat is increased by the combustion of the small coal which was scattered throughout the heap as it was built up. The top and sides of these clamps are usually built of bricks that have been already once baked. The underbaked bricks of previous firings may thus be conveniently finished. Over the whole a covering of loam is sometimes laid to prevent the fire from burning too rapidly; and screens of wood or other material are used to protect portions against the wind. The time required to burn a kiln varies with its extent and the manner in which it is fired. The English accounts state: "So very slow is the progress that bricks in the neighborhood of London take about three months in the burning." The time formerly required on the Hudson river for burning the great clamps of from 300,000 to 1,000,000 bricks was about two weeks, and the consumption of oak wood was about 40 cords to 100,000 bricks. The quantity usually regarded as sufficient is, however, 83½ cords. After the introduction of anthracite dust in the clay, the time of burning was reduced to three or four days, and the consumption of fuel to 16 cords to 100,000 bricks. The mere expenses of burning this number of bricks are rated at \$80 for 16 cords of wood, \$3 for 75 bushels of anthracite dust, and \$6 for 4 days' attendance; total, \$89. The preparation of the clay, moulding, drying, building up of the kiln, waste, &c., make all together a larger amount than the burning. As the bricks in a clamp are exposed to great differences of temperature, they are found of various qualities when the process of burning is completed. Those near the flues are partially vitrified and melted together. Many are slightly fused on the surface, and baked to a stony hard-

ness. These are called *clinker bricks*, and are used in situations where they will be exposed to the weather or to rough wear. The soft bricks are selected to be laid for work in sheltered situations. The very slackest baked are returned to the next kiln.—The annular furnace for burning brick, invented by Friedrich Hoffmann of Berlin, is extensively used in Europe, and is said to possess great efficiency and economy. The following description and illustration are taken from Dr. Barnard's report of the Paris exposition of 1867. A large annular chamber, with openings at the sides for the reception of the bricks, is constructed with a central chimney, and with removable divisions for separa-

FIG. 1.—Hoffmann's Annular Brick Furnace.

ting the annulus into different parts. When the furnace is filled with unburnt bricks heat is applied to one division, the smoke and hot air escaping into the adjoining one, which is the next to be burnt, the air for maintaining the combustion being received through the compartment last burned, whereby the bricks in it are cooled. Each compartment of bricks or other articles is thus burned in turn, the waste heat of the burning compartment continually drying the compartment before it, and taking all the heat of the one behind. The letters *a a*, fig. 1, mark the circular arched furnace, furnished with doors, *b b*. Flues, *c c*, lead to the circular chamber *e e*, surrounding the chimney,

d. Valves of cast iron are made to close at pleasure the orifices of the flues. Movable sluices in the dividing walls allow of communication to be made or closed between the chambers; *h h* are plugs through which the coal, in powder, is introduced, undergoing calcination. The advantages of this furnace lie in its great economy of fuel. The heat is very equable, and no smoke is generated, the fuel being burnt while falling to the bottom of the furnace.—The immense consumption of bricks in cities has made it an important object to reduce the labor employed in their manufacture as much as possible, and consequently much ingenuity has been expended in devising machinery for grinding and moulding the clay. A great number of machines have been patented in this country and in Europe, but it has been found exceedingly difficult to render them practically successful. Two kinds of machines have been made, one by which it is sought to prepare the brick from clay which contains so little moisture that they may be immediately taken to the kiln, and another which moulds it in so soft a state that it requires to be dried before baking. The difficulty with the first method is that the bricks do not seem to possess the strength of those which are made of moister clay, and from the immense power required to press them to the proper size in the moulds some parts of the machinery are liable to break. Those machines which employ moist clay have been utilized in manufacturing pipe and tile and peculiar forms of brick; but in making common brick the saving of labor has not been found sufficient to make them take the place of hand labor, by which process nearly all the bricks used in building are made.—The red color of bricks is owing to the peroxidation of the iron contained in the clay. If the iron is deficient or only partially oxidized through insufficient heat, the bricks are of a pale color. The clay in the vicinity of Milwaukee, Wisconsin, is remarkably free from iron, and the bricks made of it are of a delicate straw color. Other colors may be imparted to brick, provided that of the oxide of iron does not overpower all other coloring matters introduced. American bricks vary in size in the different states, running from $7\frac{1}{2}$ to $8\frac{1}{2}$ inches in length, 4 to $4\frac{1}{2}$ in width, and from $2\frac{1}{2}$ to $2\frac{3}{4}$ in thickness. The weight is commonly reckoned at 4 lbs. to the brick; but this varies with the size, the amount of pressure to which the clay has been subjected, and the heat applied in baking. English bricks are commonly 9 inches long, $4\frac{1}{2}$ wide, and $2\frac{1}{2}$ thick.—*Floating Bricks.* A very light silicious earth is occasionally met with, of which bricks have been made that float upon the water. Clay may be added to the silica, if required to bind the material together. Such bricks were made in ancient times, and were described by Posidonius and Strabo, and particularly commended by Vitruvius, Pollio, and Pliny. In 1791 they were again brought into notice by Giovanni Fabroni in Tuscany,

who after many trials succeeded in making bricks which would float upon water. Their strength was but little inferior to that of ordinary bricks. They are remarkable not only for extreme lightness, but also for their infusibility, and for being very poor conductors of heat. They may be held by one end while the other is red-hot. As an experiment Fabroni constructed the powder magazine of a wooden ship with these bricks. The vessel, being set on fire, sank without explosion of the powder. In 1882 Count de Nantes and Fournet, a mining engineer, used them in constructing powder magazines and other parts of ships, lessening danger from fire. Kützing found the material from which these bricks were made to contain immense numbers of microscopic silicious shells of infusoria. Similar earth has been discovered in France and at Berlin, and it is probably the same whitish substance that is often found under our peat bogs.—*Fire Brick.* When bricks are required to withstand high temperatures, they are made of the most infusible clays, such as contain from 63 to 80 per cent. of silica, with from 18 to 25 per cent. of alumina, and the remainder water. Oxide of iron may be present, but the light color of fire brick shows that this is in very small quantity. Lime would render the mixture fusible, and this is necessarily always absent. Such clays are of common occurrence in the bituminous coal measures, where they are found making the floor or underlying stratum of the coal beds. The material is indurated, so that it is broken up like a soft stone. When used, it is ground in a mill, and mixed with fragments of previously baked fire brick, or of some refractory stone, or with a coarse, clean silicious sand and gravel. The materials are made into a paste with water, moulded in hand moulds, and baked in permanent kilns at a very high temperature. Good clay for fire bricks is also found associated with other clays of more recent formations. The potters' clay formation found at South Amboy, N. J., contains beds of excellent quality, together with others of very pure sand, suitable for mixing with the clay. The manufacture of fire brick has long been carried on at this locality. At Athens, opposite Hudson, on the Hudson river, good fire bricks have long been made. At Bennington, Vt., an excellent clay is found of the character of kaolin, from which fire bricks of very refractory quality are made by mixing with it stones that withstand heat, crushed sufficiently fine. These bricks are extensively employed at the blast furnaces in that part of the country. It is for the lining of such furnaces that fire bricks are principally in demand, and for this use they are prepared of a variety of sizes and shapes, adapted to fit the curves in the lining of the stacks and the arches of the flues. The standard size to which all the larger bricks are referred in reckoning their number, is that of the common rectangular fire brick, which measures 9 inches in length, $4\frac{1}{2}$ in breadth, and $2\frac{1}{2}$ in

width; of these the weight is 7 lbs. These bricks, specially adapted to each pattern, are also employed as a lining for the anthracite coal stoves so extensively in use in the United States.—*Bricklaying.* The form and proportions of the faces of brick to each other are such that they may be laid in various methods, according as the object is to produce the greatest strength of wall or the most pleasing effects. Ornamental work, as cornices, beads, &c., is produced by causing courses of brick to project beyond the plane of the rest. By the introduction of mortar, bricks, notwithstanding their rectangular shape, are carried round to form arches of any desired curve; they are easily broken also into any required shape by the trowel, and thus are made to receive, if desired, the approximate form of an arch. Fire bricks, as mentioned above, are moulded in shapes for laying curves, as also common bricks for the lining of wells, &c. In laying walls, the first principle to be observed is causing the bricks of successive courses to overlap each other, so that the joint between two is overlaid by the middle of a brick. The courses are thus bound together, and the greatest resistance is offered to any force tending to separate the bricks. As the width of two bricks laid side by side equals the length of one, the position may be reversed with each course, thus securing additional strength. What is called the old English bond method of laying a wall, which is the strongest mode, is to arrange the bricks in alternate courses of stretchers and headers, the former being bricks laid longitudinally with the wall, and the other transversely, presenting their ends or heads only to the face of the wall. Next the corner,

FIG. 2.—Old English Bond.

a quarter brick on the row of headers must be introduced, so that the stretchers overlying may lap to the middle of the second headers. The headers are also called binders, from their effect in binding the bricks of the other courses together. Owing to their presenting a greater number of joints in the face of the wall, their effect is not so pleasing as is that of the stretchers. In New York city, it is required by the fire laws that one course in five shall be headers. This is effected, while stretchers only are seen on the face, by laying every fifth course in what is called herring-bone, breaking off the back corners of the stretchers to let the corners of the brick behind come nearly to the outside line of the wall. In the Flemish bond the bricks are laid alike in each course, a header and stretcher alternating along the course. The effect is more pleasing than the English

bond, but at the sacrifice of some strength. Walls vary in thickness by the difference of the width of a brick. They are 8 inches or the length of a brick thick, 12 inches or a brick

FIG. 3.—Flemish Bond.

and a half, 16 inches or two bricks, and so on. Laid in English bond, all the bricks on one course must be placed in the same direction, even when the wall turns at right angles; and in turning the corner no two bricks must be arranged side by side, but the end of one must lap to the middle of the next contiguous to it, excepting when the quarter brick is introduced at the corner to prevent a continued upright joint in the face work. The work is strengthened by the occasional introduction of pieces of hoop iron, which bind it together. If bricks were laid dry, they would absorb the moisture of the mortar, and, the pores being filled with air and the surface covered with dust, there would be no adhesion; but when the bricks are wet and the mortar moist, the evaporation makes the attachment complete. As the wall is built up, no part should at any time reach more than four or five feet above the rest; for unless all upon the same level settles together, cracks will be produced where the newer work is joined upon the older. In attaching new walls to old, a brick in every other course of the old work is drawn and the new work is toothed in.

BRIDAINE, Jacques, a French preacher and missionary, born at Chuslan, March 21, 1701, died at Roquemaure, Dec. 22, 1767. He studied for the priesthood in the Jesuit college at Avignon, and the seminary of the royal missions of St. Charles of the Cross in the same town, and on taking orders began to preach at Aigues-Mortes. Failing to secure a large congregation by ordinary means, he one day went into the streets ringing a bell, and continued to walk through the town until he had collected nearly all its inhabitants, whom he induced to follow him to church. Here he addressed them with extraordinary eloquence, and from that time he enjoyed a constantly increasing reputation. He travelled through the villages of the south of France, and his "missions" to different towns reached the number of 256. He was asked to go to Paris, and delivered there, in the church of St. Sulpice, a sermon on eternity, rousing the audience to the highest pitch of excitement, and making, as it has been described, "a terrible impression" on all who heard him. His language was simple, direct, and often rough; but his power over an audience was remarkable. There is a complete edition of his sermons (5 vols., Avignon, 1821).

BRIDGE, a structure, with one or more transverse apertures, for passing a river, canal, or valley, and formed of various materials, as timber, stone, or iron. The construction of perfect bridges is a complex operation, and among ancient nations, even of the highest civilization, did not always keep pace with the progress of the other arts. The type of the primitive bridges of earlier ages is to be found at the present day among rude and uncultivated nations, and consists simply of lintels of wood stretching from bank to bank, or, when the span renders this impracticable, resting on piers or posts fixed in the bed of the river. The inevitable frequency of these in a rapid stream, and consequent contraction of the waterway, would result in a torrent injurious to navigation, and destructive to the piers themselves; hence it would be found essential to the stability of such structures that the openings should be sufficiently wide to allow every facility for the passage of the water, and as this could only be effected by arches or trusses, it is evident that these inventions were perfected before bridges of any magnitude became common. One of the most extraordinary bridges of ancient times was that which, according to Herodotus, Queen Nitocris constructed over the Euphrates at Babylon, and the length of which is given by Diodorus Siculus as five furlongs; the construction of this bridge is supposed to have been of the kind just alluded to, viz., with lintels or architraves extended from pier to pier. The bridges of Darius upon the Bosphorus, Xerxes upon the Hellespont, Cæsar upon the Rhine, and Trajan upon the Danube, are celebrated in history, but were all constructed for purposes of war. The first examples of stone bridges that we can find are those constructed by the Romans. An exception may perhaps be made in regard to the Chinese, as we are not positively acquainted with the date of many of their structures; but in Egypt and India, the birthplaces of so many of the arts and sciences, arched bridges were entirely unknown; neither do we meet with them in the ancient remains of Persia or Phœnicia; and even in Greece, at the period when her architecture was the finest in the world, and when Pericles had adorned Athens with splendid edifices, her people were unprovided with a bridge over the Cephissus, notwithstanding it crossed the most frequented thoroughfare to the city. The principal bridges of Rome were the following: 1. The Pons Sublicius, the first built over the Tiber, and memorable from its defence by Horatius Coclès against Porsena; it was twice rebuilt, and the ruins of the last structure are still visible. 2. The Pons Triumphalis, sometimes termed Pons Vaticanus, from its proximity to the Vatican; it derived its former name from being the bridge over which those to whom the senate decreed a triumph passed on their way to the capitol. 3. The Pons Fabricius, named from its founder, L. Fabricius, *curator viarum*, who erected it during the period

of Catiline's conspiracy. 4. The Pons Cestius, built in the reign of Tiberius, and named from Cestius Gallus. 5. The Pons Janiculi, which led from the Campus Martius to the Janiculum. 6. The Pons Ælius, erected in the reign of the emperor Ælius Hadrianus; it is said this bridge had originally a roof of bronze, supported by forty columns, but was despoiled during an incursion of the barbarians. Clement IX., who restored the bridge, placed on it ten colossal statues of angels, carved in white marble, whence is derived its present name, Ponte San Angelo. 7. The Pons Milvius, built in the time of Sulla, on the ancient Via Flaminia, at a short distance from the city; on this bridge Cicero arrested the Allobrogian ambassadors who were the bearers of letters to Catiline, and here also occurred the celebrated victory of Constantine over Maxentius, when Constantine had the miraculous vision of the cross. 8. The Pons Senatorius or Palatinus, still remain-

FIG. 1.—Pons Senatorius.

ing, though in ruins, near the Palatine hill.—From the fall of the Roman empire, we have for several centuries no account of any bridges worthy of note, except those built by the Moors in Spain, one of the finest of which was the bridge of Cordova, over the Guadalquivir, built by Hashem or Issem, the son and successor of Abderrahman, the first of the Moorish kings of Spain. One of the most ancient bridges of modern Europe is that over the Rhône at Avignon. It was built by a religious society called the "Brethren of the Bridge," which, according to Gautier, "was established upon the decline of the second and commencement of the third race of kings, when the state fell into anarchy, and there was little security for travellers, particularly in passing rivers, on which they were subject to the exactions and rapacities of banditti." This society was founded with a view to remedy these evils, by forming fraternities for the object of building bridges, and establishing ferries and caravansaries on the banks of the most frequently crossed rivers; their first establishment was on the Durance, at Maupas, which name was afterward changed to Bonpas, in acknowledgment of their services. The bridge at Avignon was commenced in 1176, and completed in 1188. The association soon after built the bridge of Lyons, composed of 20 arches, and that of Saint Esprit, over the Rhône, of 19 arches, besides many other structures of less note. One of the oldest bridges in England is that of Croyland in Lincolnshire; it is formed by three semicircles which succeed each other, and are based upon a central arch; the ascent is so steep that only foot passengers can accomplish it. The bridge at Burton over the Trent, now partly removed, was the longest in England, and was built in the 12th

century; it had 36 arches of squared freestone, and was 1,545 ft. in length. The first stone bridge over the Thames, known as the old London bridge, was commenced in 1176 by Pe-

FIG. 2.—Old London Bridge in 1616.

ter of Colechurch, who is supposed to have belonged to the Brethren of the Bridge; Peter died before the completion of his work, and was buried in the crypt of the chapel erected on the centre pier; this was in accordance with a custom of the society, that when any member died during the superintendence of an important work, his remains should be entombed within the structure; the work was completed in 1209, during the reign of King John, and was chiefly remarkable for its massiveness, and enormous surplus of material, having 20 arches in a span of 940 ft., with piers varying in solidity from 25 to 34 ft., so that two thirds of the stream was occupied by the piers, and at low water a still greater proportion, leaving at that time less than one fourth of the whole span for waterway, and causing a most dangerous fall. The bridge of the Holy Trinity at Florence, over the Arno, was built in 1569; it has a total length of 322 ft., is composed of three elliptical arches, and stands unrivalled as a work of art; the material used in its construction is white marble. The Rialto at Venice, designed by Michel Angelo, and erected in 1588-'91, has a single span of 98½ ft., with 23 ft. rise. The total number of bridges in that city was estimated by Gautier at 340. The bridge of Pont-y-Prydd, over the

FIG. 3.—Bridge of Pont-y-Prydd.

Taff in Wales, is considered one of the most extraordinary in Britain; it was built in 1755, by an uneducated mason named Edwards, after the failure of two structures which he had

previously erected at the same spot; the first was carried away by a freshet after standing two and a half years, and the second failed in consequence of the weight on the haunches forcing out the keystone before the parapet was finished; the present structure consists of a single circular arch, with a span of 140 ft. and a rise of 35 ft. The bridge of Mantes, over the Seine, was erected by Perronet and Housseau in 1765, and consists of three elliptical arches, the centre one having a chord of 128

FIG. 4.—Bridge of Neuilly.

ft. The famous bridge of Neuilly was constructed by Perronet in 1774; its total length is 766 ft., with a clear waterway of 639 ft.; there are five arches of equal width, the curves being false ellipses, with chords of 128 ft. and versed sines of 32 ft. The bridge of St. Maixence, over the Oise, was also built by Perronet between 1774 and 1785; it is chiefly remarkable for the flatness of its arches, the chords being 76 ft. 8 in., while the versed sines are only 6 ft. 3 in., and the thickness of the voussoirs at the vertex of the arch 4 ft. 8 in. Waterloo bridge, over the Thames in London, built by Rennie in 1811-'17, is 1,240 ft. in length, and composed of nine elliptical granite arches, each of 120 ft. span, and a versed sine of 32 ft.; the piers are fronted with coupled Doric columns, producing an elaborate effect; another peculiarity is that the roadway is level, differing in this respect from the other bridges across the Thames. Westminster bridge, completed in 1750, by Labeleye, is remarkable as inaugurating a new era in bridge architecture; the novelty consisted in the manner of laying the foundations, which was effected by means of caissons, the depth of water and rapidity of the current rendering the expense of coffer-damming un-

FIG. 5.—New London Bridge.

desirably great; the bridge is 1,220 ft. in length, and has in all 15 semicircular arches, two of which, however, are quite small. The new London bridge is an imposing structure of granite, and was completed by Rennie in 1831; it has a total length of 928 ft., with five elliptical arches, the span of the centre arch being 152 ft., and its versed sine 29 ft. 6 in. In the United States there are comparatively few stone bridges of great size. Perhaps the finest example we have is the High bridge of the Cro-

ton aqueduct, over the Harlem river at New York; its total length is 1,460 ft., and the top of the parapet is 116 ft. above high water; there are in all 15 semicircular arches, 8 of which are of 80 ft. span, and 7 of 50 ft. (See *AQUEDUCT*.)—The arches of bridges are of three principal kinds: 1. The semicircular; these were anciently most in use, and have the advantage of being easy to construct, and forming a solid structure; their span is, however, restricted, on account of the great relative height of this form of arch, and as they are usually made of moderate size, they have the inconvenience of considerably obstructing the passage of the water. 2. Arches of a flat vault, either forming portions of an ellipse, or else described by several arcs of circles of different radii. Elliptical arches are pleasing to the eye, but troublesome to construct, on account of the continual change in the form of the successive voussoirs; hence it is usual to employ curves composed of a certain number of arcs of circles, varying generally from three to eleven. The use of flat-vaulted arches was introduced into France about the close of the 17th century, and their adoption was due to the necessity of affording a wider discharge without considerably augmenting the height of the arches. This form not only answers this object effectually, but, when the two diameters are not very unequal, presents as much solidity and facility in construction as the semicircular arch. 3. Arches formed from an arc of a circle, which are of two principal kinds: first, those in which the springing planes are under water, examples of which are seen in the bridge of Saint Esprit, and the ancient bridge of Avignon; this form has the disadvantage of greatly reducing the discharge. In the second kind the springing planes are on a level with the highest water of the river, as in the bridge de la Concorde at Paris. In this case the arc is necessarily very low, and the lateral pressure of the voussoirs so considerable as to require great care in the construction. Besides the three of which we have spoken, there is the Gothic arch, composed of two arcs of a circle, sometimes though rarely employed; it has the fault of greatly reducing the outlet. Though the size of the arches is usually determined by local circumstances, yet there are a few general principles to be considered. Small arches are best adapted to quiet rivers, whose waters do not rise to any considerable height, while large arches are best suited to torrents, where it is difficult to lay the foundations, and where the piers are exposed to damage by obstacles brought down against them by the current. Arches of stone cannot be applied, however, to the wide rivers of Europe or America. In fixing the width of arches two plans are pursued: in one, the apertures are all equal, giving the tops of the vaults the same elevation above the water, and enabling the constructor to use the same centering for all the arches. The economy of this arrangement may, however, be counterbalanced

by the necessity of forming considerable embankments at the termini of the structure. In the other plan, the diameters of the arches are unequal, allowing a reduction of the embankments, thus diminishing the obstacles to the approaches. The advantages of both systems are sometimes combined by forming the arches of the same width, and placing the springing planes at heights decreasing from the centre to either extremity of the bridge. The breadth of the bridge depends wholly on the locality, and should be proportioned to the importance of the road on which it is built. For country roads a width of 14 to 16 ft. will be sufficient, particularly if the bridge be a short one. On what are termed roads of the second class, 20 to 25 ft. should be allowed, which will afford sufficient room for two carriages to pass at once, besides a space for foot passengers. On roads of the first class, 30 to 35 ft. is considered a fair allowance, while in the interior of cities from 30 to 60 ft. will be required. The Pont Neuf at Paris, which is perhaps one of the greatest thoroughfares in the world, has a width of about 70 ft. between the parapets.—Timber, as a material for bridges, is much less costly and more easily worked than stone; but all such structures lack the advantage of durability, and are more troublesome to keep in repair. The oldest wooden bridge of which we have any account is the Pons Sublicius already mentioned; it is supposed that no iron whatever was used in its construction. Caesar's bridge was also of wood, and so was Trajan's across the Danube, though it is probable that the piers of the latter were of stone. One of the most famous wooden bridges on record is that of Johann Ulrich Grubenmann, an uneducated carpenter of Switzerland; it was built at Schaffhausen in 1757, and was composed of two wooden arches with the respective spans of 193 and 172 ft., supported at either terminus by abutments, and at their junction by a stone pier. After Grubenmann's death the bridge began to settle, as the oak beams, which had been placed too low, and not sufficiently exposed to the air, rotted at their points of contact with the stone abutments. Owing to the peculiar arrangement of the structure, by which the principal supports were so intimately connected together, it became necessary to support the whole bridge before a single part could be removed; this was performed by means of screw jacks, and the decayed timbers replaced. No other repairs were ever required, and the bridge excited much attention as a remarkable specimen of carpentry. It was burnt by the French in 1799, having lasted 42 years. In modern times, the wooden bridges of Germany and France have taken high rank from their scientific combination in arrangement, but during the last few years the United States have justly claimed the precedence for simplicity and boldness of design. The upper Schuylkill bridge at Philadelphia, which was burned in 1838, had the remarkable span of 340 ft. It was de-

signed and built by L. Wernwag, and consists of five ribs, each formed of a curved, solid-built beam, connected with an upper single beam by radial pieces, diagonal braces, and in-

FIG. 6.—Schuylkill Bridge.

clined iron stays. In the Trenton bridge, the roadway bearers are suspended from curved, solid-built beams, by iron bar chains and suspension rods; it consists of five spans, the central and widest being 200 ft. Burr's plan, which at one time received considerable favor on railroads and aqueducts, particularly in Pennsylvania, consists essentially of open-built beams of straight timber, connected with curved, solid-built beams, termed arch timbers, and which are formed of several thicknesses of scantling, between which the framework of the open-built beam is clamped. Town's plan, commonly known as the lattice truss, consists of two main strings, each formed by two or three parallel beams of two thicknesses, breaking joints with a series of diagonal pieces, crossing each other and inserted between the parallel beams, being connected with the strings and

with each other by treenails. As the timbers are of a uniform cross section and length, the construction is simple and economical, though the plan is not well adapted to the resistance of variable strains and jars. Long's truss consists in forming the upper and lower strings of three parallel beams, between which are inserted the cross pieces, or posts, which are formed of beams in pairs, placed at regular intervals along the strings, and connected with them by wedge blocks; between each series of posts are placed braces and counterbraces, suitably connected by treenails, and in long spans arch braces are also introduced. In Howe's truss, the upper and lower strings are each formed of several thicknesses, breaking joints, while on the upper side of the lower string, and the lower side of the upper, are placed blocks of hard wood or cast iron, inserted in notches, and bevelled on each side to form a support for the braces and counterbraces; through the blocks are passed bolts of iron to connect the two strings, and by means of a nut and screw any desired amount of tension can be given to the truss. The preceding combinations are those which are in general use in the United States. One of the most remarkable wooden bridges is that at Havre de Grace, over the Susquehanna river; this is 3,271 ft. long, divided

FIG. 7.—Bridge over the Susquehanna at Havre de Grace.

into 12 spans, resting upon granite piers. It is constructed upon Howe's plan, and combines great lightness and strength. There are many works of this character throughout the country, where, owing to the cheapness of timber, they can be built with great economy. The practice of American engineers in this class of structures has been taken as a guide in similar works throughout the world. The modern tendency is, however, toward the substitution of iron and steel for timber.—Suspension bridges are of very remote origin. Kirchen, in his "China Illustrated," mentions one which is still to be seen in the province of Yun-nan, and according to tradition was built by the emperor Ming in A. D. 65; it is formed of chains, supporting a roadway of plank resting directly upon them, and is 330 ft. in length. The ancient Peruvians

also constructed numerous bridges over the Andes, the principal material being ropes formed of the bark of trees; sometimes a roadway was constructed, and at others the transit was effected by means of a basket supported by the rope, and drawn over alternately from one side to the other. The same plan is used at the present day. Rope suspension bridges have also been used in Europe; they were employed in France, at the siege of Poitiers, to cross the river Clain, and Douglass mentions their use in Italy in 1742. Iron suspension bridges of large span, however, are of modern date. The first of this kind erected in England was in 1819, and was built across the Tweed at Berwick by Capt. Sir Samuel Brown; it was constructed with chain cables, 12 of which were used in all, six being placed on

either side of the roadway; its span was 449 ft. and versed sine 30 ft. The same engineer constructed the Brighton chain pier, and the bridge at Montrose. The former was built in 1823, and destroyed by a gale of wind in November, 1836; its entire length was 1,186 ft., in four openings, each of 255 ft. span and 18 ft. deflection. The latter was erected in 1829, and in October, 1838, the roadway was totally destroyed by a hurricane; Mr. Rendell reconstructed it, and materially stiffened the structure by the system of trussing he adopted. The bridge over the Menai strait, by Telford, was built in 1819-'25; its span was 580 ft., and the clear height of the roadway above the water 102 ft.; it was seriously injured by a violent gale, which produced so great an oscillation of the main chains as to dash them against each other and break off the rivet heads of the bolts; a recurrence of the accident was provided against by suitable bracing, and the iron roadway beams strengthened by an additional number constructed of timber, as it was found that the former were frequently bent and even broken by the undulations of the bridge in a gale. The Conway bridge was also built by Telford, being completed in 1826; it crosses an estuary that divides the towns of Bangor and Chester; its span is 327 ft., with a deflection of 22½ ft. The Hammersmith bridge over the Thames was built by Tierney Clark in 1824-'7, and has a span of 422 ft. One of the most remarkable suspension bridges in Europe is that of Fribourg in Switzerland; the cables are of wire, and the span is 870 ft.; it was erected in 1831-'4 by M. Chaley; the roadway is 174 ft. above the surface of the river, and although the whole is remarkably light and fragile in appearance, it has withstood several severe tests uninjured, and is still considered a safe bridge. The Pesth suspension bridge over the Danube was com-

menced in 1840 by Tierney Clark, and opened in 1849, when it was crossed by a part of the Hungarian army retreating before the Austrians, and followed immediately by the latter, both armies with their heavy trains of artillery, ammunition, and baggage wagons; it is estimated that of the Austrian troops alone 30,000 crossed the bridge in two days; the clear waterway is 1,250 ft., and the centre span 670 ft., while the towers are 200 ft. in height from the foundations. In the United States, the first suspension bridges were built by Mr. Finley between 1796 and 1810, and were all of small dimensions, and constructed with chain cables. During the last 25 years, however, a large number of structures have been erected, and some of great size; the plan of wire cables has been universally adopted in their construction. The Wheeling bridge over the Ohio was built in 1848, by C. Ellet, and blown down in May, 1854; its span was 1,010 ft. The Belview bridge at Niagara, a slight structure, was built by the same engineer in 1848, and had a span of 759 ft.; it was removed in 1854, and its cables incorporated in the bridge constructed by Mr. Roebling. One of the finest structures of this kind in the country, and perhaps in the world, is Roebling's railway bridge at Niagara; its span is 821 ft., and deflection 59 ft.; 14,560 wires are employed in the cables, and their ultimate strength is estimated at 12,000 tons; the elevation of the railway track above the water is 245 ft., and so great is the stiffness of the roadway that the passage of ordinary trains causes a depression of only three to four inches; the bridge was completed in 1855, and, though continually subjected to the passage of heavy trains, has thus far proved a complete success. This able engineer has added to his fame by the construction of a suspension bridge over the Ohio river at Cincinnati. It has a total

FIG. 8.—Suspension Bridge over the Ohio at Cincinnati.

length of 2,220 ft. and a clear span of 1,057 ft., and is 103 ft. above low water in the river. The two cables supporting the roadway are 12½ inches in diameter. A still more remarkable work of this kind was designed by Roebling to connect New York city and Brooklyn, and is now (1873) in process of construction, under the charge of his son, Washington A. Roebling. It will be 3,475 ft. long between the anchorages, with a clear span over

the East river of 1,595 ft., the bottom chord of which will be 135 ft. above the water. The superstructure will consist of an iron framing 85 ft. wide, suspended from four main cables, each 16 inches in diameter, composed of galvanized cast-steel wire, having a strength of 160,000 lbs. per square inch of section. The aggregate strength of the main span will be 5,000 tons.—Cast-iron bridges are of recent origin. The first that was erected in England

Fig. 9.—New York and Brooklyn Suspension Bridge.

was at Colebrook Dale in 1779, and consists of five curved ribs, nearly semicircular in shape, and each formed of three concentric arcs, connected by radial pieces; its span is 100 ft., and rise 40 ft. The Wearmouth bridge was built in 1790, and has a striking appearance from its great span as well as height above the water; it is 100 ft. above high-water level, and has a span of 240 ft., with a rise of 80 ft. The pont d'Austerlitz, at Paris, has five arches, each with a span of 107 ft., and a rise of $\frac{1}{10}$ the span; it was erected in 1801-'7 by Lamande. The pont du Carrousel, in the same city, was built by Polonceau in 1838, and consists of three arches, with a span of 150 ft., and a rise of 16 ft. The largest iron arch bridge is the Southwark bridge over the Thames, built by Rennie in 1815-'19; it consists of three arches, 240 ft. in span, and with a rise of 24 ft. A remarkable cast-iron bridge, combining the purposes of viaduct and aqueduct, was designed and constructed by Capt. M. O.

Fig. 10.—Washington Aqueduct Bridge.

Meigs, for the purpose of carrying the Washington aqueduct over Rock creek, between Georgetown and Washington: the peculiarity of this bridge is that its arches are constructed of cast-iron pipes, which carry the roadway and the water supply at the same time; its span is 200 ft., its rise is 20 ft., and the diameter of the two pipes of which it is formed is 4 ft. in the clear.—Of wrought-iron bridges, the

Britannia and Conway tubular bridges, both erected by Stephenson, are widely celebrated. The Britannia bridge crosses the Menai strait at 103 ft. above high water, and consists of four spans, two of 230 ft. each, and two of 459 ft.; forming a huge tube of wrought iron, through which passes the Chester and Holy-

Fig. 11.—Britannia Bridge.

head railway. The Conway bridge has a single span of 400 ft., and is only 18 ft. above the level of high water; it was finished in 1848, and the Britannia bridge in 1850. The tubes were constructed, in each instance, at a distance from their respective destinations, and afterward floated to their places by pontoons, and raised by hydraulic presses, forming the most gigantic application ever made of these powerful machines. The Victoria railway bridge, over the St. Lawrence at Montreal, constructed after the plan of the Britannia bridge, is two miles long, cost over \$5,000,000, and contains 10,500 tons of iron and 3,000,000 cubic feet of masonry. Since 1860 many iron viaducts have been built in the United States. Among the most notable of these are the rail-

road bridge across the Ohio river at Louisville, constructed under the supervision of Mr.

FIG. 12.—Lattice Girder.

Albert Fink, and in accordance with the system known by his name, the essential feature of which is that the bridge carries its load

FIG. 13.—Lattice Girder.

by the aid of suspension rods, and at the same time possesses the stiffness of a truss. The

length of this bridge is 5,218½ ft., divided into 25 spans, supported by 24 stone piers. Its entire cost was \$2,016,819. Its height is about 96½ ft. above low water. Its width is about 27 ft. The drawing (fig. 15) will show at a glance the peculiarities of this structure. The railroad bridges over the Mississippi river at Quincy,

FIG. 14.—Modified Fink trussed Girder.

Keokuk, and Burlington, and over the Missouri river at St. Charles, are good examples of truss bridges constructed exclusively of wrought iron.—Many modifications have been made in the form of the truss since the substitution of iron for wood. A very remarkable bridge, the superstructure of which is mainly composed of

FIG. 15.—Viaduct Bridge at Louisville.

steel, is now (1873) in the process of construction over the Mississippi river at St. Louis. It was designed by James B. Eads, and was begun in 1869. The piers, four in number, are composed of granite and limestone, and rest on the bed rock of the river, to which they were sunk through the sand, in one case as much as 120 ft., by the use of wrought-iron caissons and atmospheric pressure. There will be one span of 520 and two spans of 515 ft. each over the waterway. The rise of the arches

is 60 ft., sufficiently high to permit the passage of steamboats at all stages of water. The two roadways, one for railways and one for carriages, will be carried by four arched trusses connected with each other by diagonal braces, the top and bottom chords of which are composed of steel tubes 16 inches in diameter. These tubes are made in sections of about 12 ft., and consist of steel staves, banded and held together by jackets or hoops of the same material; the segments being con-

FIG. 16.—Truss Bridge at Rock Island.

neeted with each other by steel thimbles or couplings, accurately fitted and firmly secured over and about the joints. The top and bottom chords or tubes are 12 ft. apart, connected with each other by a triangular system of bra-

cing so arranged as to constitute, with the tubes, an arched truss of great lightness and strength. The width of this bridge is 54 ft., and its cost, together with the tunnel under the city of St. Louis by which access is gained to its western

FIG. 17.—St. Louis Bridge.

end, will be about \$9,000,000. (See fig. 17.) —Movable bridges are of several kinds, and receive different names from the manner in which they are constructed and operated. The term is usually applied to a platform properly supported between two points of a fixed bridge, and so constructed as to be readily removed and replaced. Drawbridges are those which are raised or lowered by means of a horizontal axis and counterpoise connected with the platform. Turning or swinging bridges are those which turn horizontally about a vertical axis, while rolling bridges are those which rest upon rollers, and can be propelled horizontally on them, so as to close or open the passage. We sometimes meet with a still different class of movable bridges, where the platform is supported by boats, or any other buoyant body, and which can be introduced in the waterway, or withdrawn from it, at convenience.

BRIDGE, Military. The art of constructing temporary bridges for the passage of troops across large rivers and narrow arms of the sea, was well known to the ancients. Darius passed the Bosphorus and Danube, and Xerxes the Hellespont, by bridges of boats. The army of Xerxes constructed two bridges across the latter strait, the first of 360 vessels, anchored head and stern alongside each other, their keels in the direction of the current, the vessels connected with each other by strong cables, over which planks were laid, fastened by a rail on either side, and covered in by a bed of earth. The second bridge had 314 vessels, and was similarly constructed. According to Arrian, Alexander had a regular pontoon train of light boats attached to his army. The Romans had wickerwork vessels, covered with hides, destined to support the timber platform of a bridge; these formed a part of the train of their armies until the end of the empire. They, however, also knew how to construct a more

solid kind of military bridge, whenever a rapid river had to be crossed; witness the famous bridge on piles, on which Cæsar passed the Rhine from Gaul into Germany in 55 B. C. The bridge was built, according to the best authorities, somewhere in the region between Coblenz and Andernach. Its construction occupied the army for ten days. During the middle ages we find no notice of bridge equipages, but during the thirty years' war the various armies engaged carried materials with them to form bridges across the large rivers of Germany. The boats used were very heavy, and generally made of oak. The platform of the bridge was laid on trestles standing in the bottoms of these boats. The Dutch first adopted a smaller kind of vessel, flat-bottomed, with nearly vertical sides, pointed head and stern, and both ends projecting, in an inclined plane, above the surface of the water. They consisted of a framework of wood, covered with sheets of tin, and were called pontoons. The French, too, according to Follard, claim the invention of pontoons made of copper, and are said to have had about 1672 a complete pontoon train. By the beginning of the 18th century all European armies had provided themselves with this kind of vessels, mostly wooden frames, covered in with tin, copper, leather, or tarred canvas. The latter material was used by the Russians. The boats were small, and had to be placed close together, with not more than 4 or 5 ft. clear space between them, if the bridge was to have any buoyancy; the current of the water was thereby greatly obstructed, the safety of the bridge endangered, and a chance given to the enemy to destroy it by sending floating bodies against it. The pontoons now employed by the continental armies of Europe are of a larger kind, but similar in principle to those of 100 years ago. The French have used since 1829 a flat-bottomed vessel with nearly vertical sides, di-

minishing in breadth toward the stem, and also, but a little less, toward the stern; the two ends rise above the gunwales and are curved like those of a canoe. The dimensions are: length, 31 ft.; breadth at top, 5 ft. 7 in.; at bottom, 4 ft. 4 in. The framework is of oak, covered with fir planking. Every pontoon weighs 1,658 lbs., and has a buoyancy (weight of cargo which would sink the vessel to the top of the gunwales) of 18,675 lbs. When formed into a bridge, they are placed at intervals of 14 ft. clear space from gunwale to gunwale, and the road of the bridge is 11 ft. wide. For the advanced guard of an army a smaller kind of pontoon is used, for bridging over rivers of less importance. The Austrian pontoons are similar to the larger French pontoon, but divided transversely in the middle for more convenient carriage, and put together in the water. Two vessels placed close alongside each other, and connected by short timbers, a longitudinal timber supporting the balks of the platform, constitute a floating pier of a bridge. These pontoons, invented by Birago, were introduced in 1823. The Russians have a framework of wood for their pontoons, so constructed that the centre pieces, or thwarts, may be unshipped; over this frame is stretched sail cloth, covered with tar or a solution of india rubber. They are in length 21 ft. 9 in., breadth 4 ft. 11 in., depth 2 ft. 4 in., and weigh 718 lbs. each. Breadth of road of bridge, 10 ft.; distance from pontoon to pontoon, 8 ft. The Russians also have pontoons with a similar framework, covered over with leather. The Prussians are said to have been the first to divide their pontoons transversely into compartments, so as to prevent one leak from sinking them. Their pontoons are of wood and flat-bottomed. The span or clear distance between the pontoons, in their bridges, varies from 8 to 16 ft., according to circumstances. In all continental armies small boats to carry out the anchors accompany the pontoon train. Pontoons of inflated india rubber were introduced in the United States army in 1846, and used in the war against Mexico. They are easily carried, from their lightness and the small space they take up when folded; but besides being liable to be damaged and rendered useless by friction on gravel, &c., they partake the common faults of all cylindrical pontoons, and have been discarded both by the United States and England. —A pontoon train contains, besides the pontoons, the oars, boat hooks, anchors, cables, &c., necessary to move them about in the water, and to fix them in their position, and the balks and planks (chesses) to form the platform of the bridge. With boat pontoons, every pontoon is generally secured in its place, and then the balks and chesses stretched across; with cylindrical pontoons, two are attached to a raft, which is anchored at the proper distance from the end of the bridge, and connected with it by balks and chesses. Where circumstances admit of it, whole links, consisting of three,

four, or five pontoons bridged over, are constructed in sheltered situations above the site fixed on for the bridge, and floated down successively into their positions. In some cases, with very experienced pontoniers, the whole bridge has been constructed on one bank of the river and swung round by the current when the passage was attempted. This was done by Napoleon when crossing the Danube, the day before the battle of Wagram.—Pontoon trains are, however, not always at hand, and the military engineer must be prepared to bridge over a river, in case of need, without them. For this purpose a variety of materials and modes of construction are employed. The larger kind of boats generally found on navigable rivers are made use of for bridges of boats. If no boats are to be found, and the depth or configuration of bottom of the river renders the use of floating supports necessary, rafts of timber, floats of casks, cotton bales, and other buoyant bodies may be used. If the river is shallow, and has a hard and tolerably level bottom, standing supports are constructed, consisting either of piles, which form the most durable and the safest kind of bridge, but require much time and labor, or of trestles, which may be easily and quickly constructed. Sometimes wagons loaded with fascines, &c., and sunk in the deeper places of the river, will form convenient supports for the platform of a bridge. Inundations, marshes, &c., are bridged over by means of gabions. For narrow rivers and ravines, where infantry only have to pass, various kinds of suspension bridges are adopted; they are generally suspended by strong cables.—The construction of a military bridge under the actual fire of the enemy is now a matter of but rare occurrence; yet the possibility of resistance must always be provided for. On this account the bridge is generally constructed in a reëntering bend of the river, so that the artillery placed right and left sweeps the ground on the opposite bank close to where the bridge is to land, and thus protects its construction. The concave bank, moreover, is generally higher than the convex one, and thus in most cases the advantage of command is added to that of a cross fire. Infantry are rowed across in boats or pontoons, and established immediately in front of the bridge. A floating bridge may be constructed to carry some cavalry and a few light guns across. The division of the river into several branches by islands, or a spot immediately below the junction of some smaller river, also offers advantages. In the latter, and sometimes in the former case, the several links of the bridge may be composed in sheltered water, and then floated down. The attacking party, having commonly to choose between many favorable points on a long line of river, may easily mislead his opponent by false attacks, and then effect the real passage at a distant point; and the danger of scattering the defending forces over that long line is so great, that it is pre-

ferred to keep them concentrated at some distance from the river, and march them in a body against the real point of passage as soon as it has once been ascertained, and before the enemy can have brought over all his army. It is from these causes that in none of the wars since the French revolution has the construction of a bridge on any of the large rivers of Europe been seriously contested.

BRIDGE, Natural. I. In Rockbridge co., Virginia, 115 m. W. of Richmond, and 160 m. S. W. of Washington. It is distant by stage road from Lexington, the capital of the county, 14 m.; is 30 m. from Bonsack's, the nearest station on the Virginia and Tennessee railroad, and 86 m. by canal boat from Lynchburg. It is situated at the extremity of the deep chasm in which flows the little stream

Arch of the Natural Bridge of Virginia.

called Cedar creek, across the top of which, from brink to brink, there extends an enormous rocky stratum, fashioned into a graceful arch. The bed of the stream is more than 200 ft. below the surface of the plain, and the sides of the chasm, at the bottom of which the water flows, are composed of solid rock, maintaining a position almost perpendicular. The walls do not seem to be water-worn, but suggest the idea of an enormous cavern, that in remote ages may have been covered for miles by the continuation of that stratum of which all that now remains is the arch of the natural bridge. A plumb line dropped from its centre down the vertical face of the rocks

swings clear at the depth of 40 ft., which is the thickness of the crown of the arch. Toward its sides this regularly increases with a graceful curve, as in an artificial structure. Its breadth is full 60 ft., and the stone is a highly silicious limestone, extremely hard to break, formed in massive blocks and strata, with no evidence upon its weathered surface of a tendency to decompose and crumble away. It is thus apparent that the insignificant little stream which now runs in this deep gorge has had no agency in shaping and producing this wonderful channel. Mightier forces have worn away the hard strata, more powerful torrents than any that now flow over the surface—set in motion probably when this portion of Virginia was shaken by those great convulsions which displaced its piles of strata to the depth of thousands of feet, bringing into juxtaposition, along the line of fissures which are still to be traced, groups of rock everywhere else found separated by other formations, the aggregate thickness of which might be measured by miles. The mineral springs so common in this region, and particularly along the lines of these disturbances, flow up from great depths, as is made evident by the high temperature of many of them. Across the top passes a public road, and being in the same plane with the neighboring country, one may cross it in a coach without being aware of the interesting pass. There are several forest trees of large dimensions growing near the edge of the creek directly under the arch, which do not nearly reach its lowest part. The most imposing view is from about 60 yards below the bridge, close to the edge of the creek; from that position the arch appears thinner, lighter, and loftier. A little above the bridge, on the western side of the creek, the wall of the rock is broken into buttress-like masses, which rise almost perpendicularly to a height of nearly 250 ft., terminating in separate pinnacles which overlook the bridge. On the abutments of the bridge there are many names carved in the rock of persons who have climbed as high as they dared on the face of the precipice. Highest of all for nearly three quarters of a century was that of George Washington, who when a youth ascended to a point never before reached, but which was subsequently surpassed in 1818 by James Piper, a student in Washington college, who actually climbed from the foot to the top of the rock. **II.** In Walker co., Alabama, is a natural bridge said to rival that of Virginia. It is in the sandstone called millstone grit, which underlies the coal formation. It spans about 120 ft., and its height is about 70 ft. A smaller bridge connects it with the bluff beyond. The lines of stratification of the sandstone give the structure the appearance of having been artificially built up with massive blocks. It is in the midst of a region of wild and romantic beauty, high escarpments of the same sandstone being seen standing out in the face of the hills around. There is a similar bridge

in Christian co., Kentucky, 180 ft. high, with a span of 70 ft. **III.** California has five natural bridges, the largest of which is on a small creek emptying into the Hay fork of the Trinity river, where a ledge of rock 3,000 ft. wide crosses the valley. Under this runs the creek, through an arch 20 ft. high by 80 ft. across. The rock above the arch is 150 ft. deep. On Lost river, in Siskiyou co., there are two natural bridges about 30 ft. apart. The rock is a conglomerate sandstone, and each bridge is from 10 to 15 ft. wide, while the distance across the stream is about 80 ft. One of these bridges is visited regularly by travellers. On Coyote creek, in Tuolumne co., 10 m. N. of Sonora, are two natural bridges, half a mile apart. The upper bridge is 285 ft. long with the course of the water, and 36 ft. high, with the rock 30 ft. deep over the water. The lower bridge is similar in size and height to the other.

BRIDGEND, a market town of Glamorgan-shire, Wales, 17 m. W. by N. of Cardiff, 190 m. from London by rail; pop. about 3,000. It is beautifully situated in a fertile district on the Ogmore, which divides it into two parts called Oldcastle and Newcastle, connected by two stone bridges. The Welsh name of the place is Pen-y-Bont-ar Ogwr. Its general appearance is picturesque; the streets are irregular, and the houses mostly of stone and well built. The town is lighted with gas, and contains a new Gothic church and several other fine public buildings. Its chief support arises from its position as a market town placed between a mineral and an agricultural population. The river Ogmore is much resorted to for salmon fishing, and also for trout and a fish called the gwyniad, which is very abundant. About two miles from Bridgend are the extensive ruins of Coity castle.

BRIDGENTHORTH, a parliamentary and municipal borough and town of Shropshire, England, on both sides of the Severn, 18 m. S. E. of Shrewsbury; pop. of the town and borough in 1871, 15,436, of whom 5,871 were in the town. It is said to be of Saxon origin, and was anciently called Brugia, Brug, or Bruges. The town consists of an upper and a lower part, connected by a handsome bridge of six arches. The upper town is built on a rock, on the summit of which stand an old castle and two churches. A free grammar school founded in 1503, a national school founded in 1847, a town hall of considerable antiquity, a public library, and a theatre are among the most notable buildings in the place. An extensive carrying trade is maintained on the Severn, and there are carpet manufactories and large mills for spinning worsted; tobacco pipes and nails are also manufactured.

BRIDGEPORT, a city and half shire town of Fairfield co., Conn., situated on Long Island sound, 59 m. N. E. of New York, by the New York and New Haven railroad. It is the most important station on the road, and a terminus

of the Housatonic and Naugatuck railroads. The mouth of the Pequonnock creek furnishes a harbor safe and capacious, but somewhat injured by a sand bar. Much coasting business is done here, and steamboats make daily passages to and from New York. Near the shore the land is level, but soon rises to an elevation of 100 ft., called Golden hill, commanding a beautiful view of the sound, and crowned with elegant residences. The city is well built, has a gas and a water company, and many of its streets are shaded with large elms. The immediate vicinity was settled in 1639, but the city (formerly called Newfield) is almost wholly the growth of the present century. The town, formerly a part of Stratford, was incorporated in 1821, and the city charter was obtained in 1836. The population of the city in 1850 was 6,080; in 1860, 13,299; and in 1870, 18,969; of the town in 1870, 19,835. The value of the taxable property of the town in 1871 was \$10,512,156, which amount was exceeded only by that of three other towns in the state, Hartford, New Haven, and Norwich. In 1871 there were in the town 18 schools, with 7 male teachers, 43 female teachers, 3,605 pupils registered in the public schools, and 498 in private schools. The city contains 5 national banks and three savings banks, with deposits aggregating, Jan. 1, 1871, \$4,473,102. Bridgeport is noted for its manufactures of firearms and sewing machines. Among the most extensive establishments are those of the Wheeler and Wilson and Howe sewing machine companies, the Union metallic cartridge company, the New Haven arms company, and one of the largest carriage manufactories in the United States. There are seven other carriage factories, several iron foundries, manufactories of locks, saddles, harness, carriage springs, and coach lace, and two daily newspapers.

BRIDGET, or *Bride, Saint*, patroness of Ireland, born at Fochard, county Armagh, about the end of the 5th or the beginning of the 6th century. She withdrew from the world in early youth, received the habit of a nun at the hands of St. Mel, nephew and disciple of St. Patrick, and built herself a cell under a large oak, calling it Kill-dara, or Kildare, the cell of the oak. She was soon followed by other virgins from the surrounding country, and in a short time found herself at the head of a flourishing order, which extended into different parts of Ireland, and even passed into England, Scotland, Germany, and France. It subsisted for many centuries, but is now extinct. Several biographies of this saint have been written, but they contain little more than a recital of her miracles. It is related that her body was discovered in 1185, at Down-Patrick, and was there kept until the destruction of its shrine by Henry VIII. The head is said to be still preserved in the Jesuits' church at Lisbon. Her feast falls on Feb. 1.

BRIDGET, *Sisters of Saint*, a religious order founded in 1806 by Dr. Delany, bishop of Kil-

dare and Leighlin, Ireland, and subsequently approved by the pope. The rule embraces the three vows of poverty, chastity, and obedience, and has special reference to the direction of parish schools. The habit is black, similar to that of the Presentation nuns and the Sisters of Mercy. The first convent of the order was opened at Tullow, county Carlow, and the second at Mount Rath, in 1808. One was established at Buffalo, N. Y., about 1853.

BRIDGETON, a city, port of entry, and the capital of Cumberland co., New Jersey, situated on both sides of Cohansey creek, 20 m. from its entrance into Delaware bay, 60 m. S. S. W. of Trenton, and 40 m. S. of Philadelphia, with which it is connected by the West Jersey railroad; pop. in 1870, 6,830. The city is divided into three wards, is neatly built, and its opposite parts are connected by a drawbridge across the creek. It contains 8 churches, a court house, a bank, two academies, a public library, and two newspaper offices, also an extensive iron foundry, a rolling mill, nail, glass, and woollen factories, besides other manufactories. Ship building forms an important industry; 18 vessels (12 sailing and 1 steam) of 389 tons were built here in 1870. The trade of the city employs a large number of schooners and sloops. In 1871 the total number of vessels registered, enrolled, and licensed here was 282, with an aggregate tonnage of 15,118 tons. The town of Cohansey was annexed to Bridgeton in 1868.

BRIDGETOWN, a city and the capital of Barbadoes, situated on Carlisle bay at the S. W. end of the island; pop. about 24,000. It is about 2 m. long and half a mile wide, and is the principal port of the island. Besides many fine houses surrounded with extensive grounds, it contains a handsome square, called Trafalgar square, in which a bronze statue of Lord Nelson was placed in 1818. There are also a cathedral, a Jewish synagogue, numerous churches and schools for blacks and whites, a handsome market place, the barracks, and several hospitals. The town contains some excellent literary and scientific societies and good libraries; a free public library was established in 1847. Bridgetown is the residence of the bishop of Barbadoes and of the governor general of the Windward Islands. The town was founded about the middle of the 17th century, but was almost entirely destroyed by fire in 1766. It also suffered severely from fire in 1845.

BRIDGEWATER (Indian name, *Nunketess*), a township of Plymouth co., Mass., on the Fall River and Bridgewater branch railroads, 27 m. S. E. of Boston, and 20 m. N. W. of Plymouth. It once formed part of Duxbury, was purchased of the Indians in 1645 by Capt. Miles Standish, and was incorporated as a separate precinct in 1716. In 1790 it contained 4,975 inhabitants; three new townships were afterward separated from it, and incorporated as East, North, and West Bridgewater.—**OLD BRIDGEWATER** is plea-

santly situated on Taunton river, embraces some of the best land in the county, and possesses considerable commercial importance; pop. in 1870, 3,660. It is the seat of a state normal school, with a library of 5,000 volumes; of an academy, incorporated in 1799; and of a state almshouse. There are 15 or 20 public schools, and Episcopal, Swedenborgian, and Congregational churches. The town contains 2 rolling and slitting mills, a forge manufacturing anchors, chain cables, &c., a brass foundry, a paper mill, 3 saw mills, 2 manufactories of hollow ware and castings, 2 of cotton gins, 1 of cotton, woollen, and other machinery, 1 of metal sheathing for vessels, and 2 of tin ware. A weekly newspaper is published here.—**EAST BRIDGEWATER** is about 25 m. S. S. E. of Boston, on Beaver and Santucket rivers, branches of the Taunton; pop. in 1870, 8,017. It has important manufactures, some of which have been carried on since its first settlement, about 1688. Cannon were cast here during the revolution. The town contains 2 shoddy mills, 2 rolling and slitting mills, 2 forges manufacturing bar iron, 6 saw mills, 1 manufactory of cotton gins, and 2 of tacks and brads; 299 males and 97 females are engaged in the manufacture of boots and shoes. A weekly newspaper is published here. There are several churches and good schools.—**NORTH BRIDGEWATER** is about 20 m. S. E. of Boston, on the Fall River railroad, and is watered by the Salisbury river; pop. in 1870, 8,007. It has a good soil, adapted to grazing, and contains Congregational, Swedenborgian, Baptist, and Methodist churches, a weekly newspaper, and good schools; 1,059 males and 208 females are employed in the manufacture of boots and shoes. There are also manufactories of mechanics' tools, tacks, brads, lasts, shoe pegs, blacking, musical instruments, tin ware, &c.—**WEST BRIDGEWATER** is about 25 m. S. E. of Boston, on the Fall River railroad; pop. in 1870, 1,808. A branch of the Taunton river flows through it, affording motive power to several mills and factories. There are 4 saw mills, 3 manufactories of hollow ware and castings, and 1 of soap; and 144 hands employed in the manufacture of boots and shoes. There are churches of various denominations and several schools.

BRIDGEWATER, a seaport, parliamentary borough, and parish of Somersetshire, England, on the river Parret, the Bristol and Exeter railway, and the Taunton and Bridgewater canal, 29 m. S. W. of Bristol; pop. in 1871, 12,101. It is a place of much antiquity, mentioned in "Domesday Book" by the name of Brugie. The Parret admits vessels of 200 tons, and opens on the Bristol channel. The foreign trade is principally with the United States, Canada, the West Indies, and Russia. About 8,500 tons of shipping belong to the port. Brick and tile making is carried on in the neighborhood, the making of white brick, known as Bath brick, constituting a staple trade of the town. The parish church is a fine structure. There

are places of worship for Unitarians, Quakers, Independents, Methodists, and Baptists; also various schools and charitable institutions. In the neighborhood is the isle of Athelney, in which Alfred took refuge from the Danes. At the conquest many Saxons were settled here. It was a place of importance in the various civil wars of England, and attained a celebrity from the part taken by its inhabitants in the Monmouth rising, and the retaliation therefor.

BRIDGEWATER, Francis Egerton, second and last duke of, an English nobleman, born in 1736, died March 8, 1803. He is chiefly known for having opened the first navigable canal in England, from his coal mines of Worsley to Manchester, which was subsequently extended to connect the Trent and Mersey. This canal, which was wholly constructed by the duke, not only largely increased his revenue from the mines, but reduced the price of coal at Manchester 50 per cent. (See BRINDLEY, JAMES.)

BRIDGEWATER, Francis Henry Egerton, earl of, born Nov. 11, 1758, died in Paris, Feb. 11, 1829. He was the second cousin of the preceding, and the youngest son of John Egerton, bishop of Durham, grandson of John, 8d earl of Bridgewater, whose direct ancestor was Sir Thomas Egerton, lord chancellor of England. (See EGERTON.) He graduated at Oxford in 1780, in which year his father appointed him a prebendary of Durham. His relative, the last duke of Bridgewater, presented him to valuable rectories in Shropshire in 1781 and 1797. His brother John succeeded to the earldom on the extinction of the dukedom of Bridgewater in 1803. Twenty years later Mr. Egerton himself became the eighth and last earl, dying a bachelor. He resided during the latter part of his life in Paris, where he was distinguished for his eccentricities. His house was nearly filled with cats and dogs; out of fifteen dogs, two were admitted to his table, and six, dressed up like himself, were frequently seen alone in his carriage, drawn by four horses and attended by two footmen. His own publications are a splendid edition of the "Hippolytus" of Euripides, with scholia, notes, various readings, and a Latin version; a "Life of Lord Chancellor Egerton;" a "Letter to the Parisians on Inland Navigation;" and "Anecdotes" of his own family. He bequeathed his manuscripts and autograph letters to the British museum, with £12,000, the interest of which was to be expended in taking care of and increasing them. Further, by his will, dated Feb. 25, 1825, he left £8,000 to the president of the royal society, to be given to some person or persons named by him, who should write, print, and publish 1,000 copies of a work "on the power, wisdom, and goodness of God, as manifested in the creation." Mr. Davies Gilbert, who occupied the chair of the royal society when the earl died, decided that eight treatises, devoted to the illustration of separate branches of the subject, should be written. Thus originated the "Bridgewater Treatises,"

whose authors were Thomas Chalmers, D. D., John Kidd, M. D., William Whewell, D. D., Sir Charles Bell, Peter Mark Roget, M. D., William Buckland, D. D., the Rev. William Kirby, and William Prout, M. D. These works have had a large and continuous sale; and, by the terms of the bequest, the profits of the treatises are appropriated to their respective authors. The earl's immense property, about £100,000 a year, in the first instance, came into possession of his kinsman, the duke of Sutherland. On his death in 1833, it devolved upon the duke's second son, Lord Francis Leveson Gower, who then took the name and arms of Egerton only, and was created Viscount Brackley and earl of Ellesmere in 1846.

BRIDGMAN, Laura, a blind deaf mute, born at Hanover, N. H., Dec. 21, 1829. Up to the age of two years she possessed all her faculties, but a severe illness at that time occasioned the loss of sight and hearing, and consequently of speech, while the sense of smell was also destroyed, and that of taste greatly impaired. She recovered her health gradually, but none of her lost senses were restored. At the age of eight she became an inmate of the Perkins institution for the blind in Boston, under the care of Dr. S. G. Howe, and soon acquired such a familiarity with the building and its various apartments that she could wander at will through it unattended. Dr. Howe resolved to undertake the task of instructing her, a work which until that time had never been attempted with success. The first step was to teach her the names of objects; for this purpose an object with which she was familiar, such as a fork or spoon, was put into her hand, and with its name in raised letters. This was repeated many times and with different objects, till she had learned that the word bore some relation to the object. As yet, however, her idea of this relation was very vague. The next step was to present her the separate letters in relief, at first so arranged as to form the name of an object which she knew. Finding that she recognized the word, her teacher disarranged the letters, and taking her hands in his own proceeded to reconstruct the word, causing her to observe each letter which composed it; having done this several times, she constructed the word herself without assistance. The same process was then repeated with other words, and before the close of her lesson the idea had evidently dawned upon her mind that this was a means by which she could communicate her own thoughts to others. This process was continued until she had become familiar with a considerable number of words. She was then furnished with type having the letters in relief, and a board which had been pierced with holes for the reception of the type. Objects known to her were then presented, and she would compose the names with the type. This afforded her great delight. She was next taught the manual alphabet, which she acquired very

readily. This having been attained, her teacher presented her with an object with which she was not familiar, and left her for a time to inform herself concerning its form and use. The teacher then spelled its name with the manual alphabet, the child following each letter till she had comprehended that it was the name of the object, when she herself spelled it in the same way, then composed it with her types, and finally, as if to make assurance doubly sure, placed the word thus composed by the side of the object. All this was accomplished in the first three months. The same course, together with some lessons on the physical relations of objects, was continued through the year. Laura never wearied of this instruction, but when left to herself was constantly spelling words either with her type or the manual alphabet. Her instruction was confined for the first two years to the names of objects; the attempt was then made to instruct her in their qualities, and subsequently in their relations to each other. There were many difficulties connected with each step, but patience and perseverance overcame them all. She was next taught to write, and her first effort was to write a letter unassisted to her mother. She subsequently acquired the rudiments of arithmetic; took lessons on the piano, on which she became a skilful performer; and acquired a practical knowledge of needlework, and of some household duties. The ideas she acquired were constantly the subjects of thought and inquiry. She one day addressed to Dr. Howe this question: "Man has made houses and vessels, but who made the land and the sea?" The answer that it was God who made all things, and the explanation of his character, affected her deeply. She sought to know more of this wonderful being, and did not rest satisfied till her teachers had explained to her the great truths of revelation. The fear of death, which had formerly distressed her, passed away with the entrance of the hope of a resurrection. In deportment she is modest almost to diffidence. She possesses a decided love of system and neatness, never leaving her room in disorder, and exhibiting great solicitude for propriety and taste in the arrangement of her dress. She exhibits a marked regard for the rights of others, and is at the same time jealously mindful of her own. She is now (1873) in her 44th year, and makes her home most of the time at the Perkins institution. Dr. Howe writes: "She enjoys life quite as much, probably more, than most persons do. She reads whatever books she finds in raised point, but especially the Bible. She makes much of her own clothing, and can run a sewing machine. She seems happiest when she can find some person who knows the finger alphabet and can sit and gossip with her about acquaintances, the news, and general matters. Her moral sense is well developed."

BRIDLINGTON (formerly written **BRELLINGTON**, and usually called **BURLINGTON**), a parish

of the East Riding of Yorkshire, England, on the railway from Hull to Scarborough, on the North sea, 6 m. W. S. W. of Flamborough Head and 25 m. N. N. E. of Hull. It includes the market towns of Bridlington and Bridlington Quay; pop. in 1871, 9,662. The town of Bridlington is built chiefly along one narrow street, and contains the remains of a priory built in the 13th or 14th century, and now used for the parochial church. There are also places of worship for several dissenting sects, three or four schools, and manufactories of hats. It gives the title of earl to the Cavendish family.—Bridlington Quay is situated on a fine bay about a mile from Bridlington, and is much resorted to in summer for bathing. There is here a chalybeate spring. The town has a good harbor, formed of two handsome piers, and an active export trade in corn. Paul Jones captured here the convoy of the Baltic fleet, Sept. 21, 1779.

BRIDPORT, a seaport town and municipal and parliamentary borough of Dorsetshire, England, 127 m. S. W. of London; pop. in 1871, 7,666. It is an ancient town, consisting mainly of three spacious streets. The fine old parish church of St. Mary was restored in 1865; among other places of worship is a handsome Congregational church. The town hall, completed in 1860, is a good building. There is a literary and scientific institution, and a school of art. The coasting trade, which was formerly considerable, was diminished by the railways; but it has recently increased owing to the improvement of the harbor, which is 1½ m. from the town, at the mouth of the Brit, and can accommodate vessels of 200 tons. Ship building is carried on to some extent; there are two weekly markets and two annual fairs for cattle, sheep, cheese, and small wares. Bridport was a borough during the Saxon period, and under Henry VIII. enjoyed the monopoly of supplying the navy with cordage. The name "Bridport dagger" was formerly applied to the halter.

BRIE (anc. *Brigensis pagus* or *saltus*), a former district of France, lying between the Seine and the Marne, and now contained in the departments of Aisne, Seine-et-Marne, Marne, and Seine-et-Oise. It was divided into Brie Française, which belonged to the government of Île de France, and Brie Champenoise, comprised in the government of Champagne. A third division once existed, called Brie Pouilleuse, comprising the environs of Château-Thierry; this was afterward incorporated with Brie Champenoise. The latter was the largest of the divisions, and had for its capital Meaux, the most important town in the whole district. Its chief wealth was in vineyards and pastures; and its butter and cheese are celebrated. Brie Française produced grain in great abundance, and was likewise a good grazing country. Its capital was Brie-Comte-Robert. Corbeil, one of its principal towns, was an independent earldom from 946 to 1122, when it was taken from

Count Hugues du Puiset by Louis the Fat. In ancient times this district was partly covered by a vast forest, portions of which are still to be seen. It is believed by some to be the much disputed country of the Meldi, of whom Cæsar makes mention. It was subjugated by the Franks, and formed part of the kingdom of Neustria. In the 9th century it was ruled by its own counts, who took their title from Meaux, but are also styled counts of Brie. Herbert of Vermandois, one of these feudal lords, having obtained the county of Troyes or Champagne, in 968 united the two districts. Both passed to the crown in 1861.

BRIEF (Lat. *brevis*, *breve*; Fr. *bref*, short). **I.** A writ issuing out of any court in the name of the king; though more strictly the name of the original writ by which a suit was commenced, it was afterward applied to all judicial writs. The reason of the name, as explained by Bracton (which, however, was only in reference to the original writ), was that it briefly set forth the subject matter of the action and the claim of the plaintiff. **II.** In ecclesiastical law, a pontifical letter addressed to inferior ecclesiastics or to temporal princes upon some matter of discipline or claim of the church, called an apostolical brief. This designation may have been used as expressing the concise form of the brief as compared with the more ample phraseology of the pope's bull. A similar use of the term was made in respect to a letter from the king in reference to ecclesiastical matters. **III.** In modern law, a summary of a case made out for the use of counsel, containing an abstract of the pleadings, a statement of the facts that can be proved, and a list of witnesses with a specification of what each can testify to. In England this is prepared by the attorney. In this country counsel often make up their own brief, and the word generally denotes the heads of a law argument, with citations of authorities, which are not only used for the convenience of counsel, but are furnished to the court.

BRIEG, a town of Prussian Silesia, on the left bank of the Oder, and on the railway from Breslau to Vienna, 28 m. S. E. of Breslau; pop. in 1871, 15,367. It contains a castle, the residence of the old counts of Brieg, several churches, a synagogue, a lunatic asylum, a gymnasium, and an arsenal. Its fortifications were destroyed by the French in 1807. Its principal trade is in cloths, tobacco, and starch,

and its cattle fairs are the most important in the province. There are extensive manufactories of linens, woollens, and cottons.

BRIEL, **Brill**, or **Brielle** (properly **BREEDE HIL**), a fortified seaport town of Holland, province of South Holland, on the left bank and near the mouth of the Maas, on the N. coast of the Voorne island, 14 m. W. of Rotterdam; pop. about 7,000. The principal church is that of St. Catharine's, and among other public buildings are a synagogue, a Latin school, an ancient orphan asylum, and an arsenal. There are several manufactories, and the principal trade is in cereals and madder. About 5 m. above the town is the entrance to the new Voorden canal across the Voorne island, by which large ships pass from the Maas to Hellevoetsluis. Admiral Marten van Tromp and Vice Admiral Van Almonde were natives of Briel. The first victory of the Dutch patriots over Spain was achieved here, April 1, 1572.

BRIENNE, or **Brienne-le-Château**, a town of France, in the department of Aube, 14 m. N. W. of Bar-sur-Aube; pop. in 1866, 2,078. It takes its name from a magnificent château erected in the 18th century by Louis de Loménie, the last count of Brienne. The military college of Brienne, founded in 1770, was attended by Napoleon from 1779 to 1784. It was suppressed in 1790, and the buildings no longer exist. On Jan. 29, 1814, Napoleon attempted here the manoeuvre of cutting the Silesian army in two, by marching suddenly from Châlons, and inter-

Military School of Brienne.

posing his forces between Schwarzenberg and Blücher, so as to prevent their junction. A severe contest ensued, with advantage to the French, but without important results. By his will Napoleon left 1,000,000 francs to the town and 200,000 to the inhabitants.

BRIENZ, **Lake of**, in the S. E. part of the canton of Bern, Switzerland, formed by the expansion of the river Aar, and connected with

the lake of Thun. It is about 8 m. long and 2 m. broad, and is embosomed in mountains, some of which, on the south, project in high promontories into the lake. Cascades from these mountains are abundant, the principal of which is the Giessbach. The surface of the lake is about 1,700 ft. above the sea. In the river Aar, E. of the lake, are the falls of Reichenbach and Alpbach, the former celebrated for its cascade of 2,000 ft., and the latter for its triple iris in the morning. The village of Brienz is at the N. E. end of the lake, near the entrance of the Aar; pop. in 1868, 4,168.

BRIER CREEK, a small stream rising in Warren co., Ga., flowing S. E. for about 100 m., and entering the Savannah river a few miles E. of Jacksonborough. After the American victory on Kettle creek, in February, 1779, Gen. Ashe was sent at the head of about 1,200 continental troops to drive the British from Augusta. The latter, under the command of Gen. Campbell, evacuated the city, retreated to Brier creek, and after crossing destroyed the bridge. Ashe pursued them, arrived at the creek Feb. 27, and while halting to form a camp, March 3, was surprised by 1,800 British under Gen. Prevost, who crossed the stream 15 m. above, made a wide circuit, attacked his rear, and routed him with a loss of about 150 killed and 189 prisoners, besides all the baggage, 7 pieces of cannon, about 500 stand of arms, and much ammunition. The British had only 5 killed and 11 wounded, and were enabled by this victory to reoccupy Augusta and open a free communication with the Indians and Tories in Florida, western Georgia, and the Carolinas.

BRIES (Hun. *Breenó-Bánya*), a town of Hungary, in the county of Zólyom, on the Gran, 24 m. N. E. of Neusohl; pop. in 1870, 11,776, nearly all Slovaks. The inhabitants are chiefly engaged in agriculture and cattle breeding. The cheese of Bries is famous.

BRIIGGS, Charles Frederick, an American author and journalist, born on the island of Nantucket about 1810. Early in life he removed to the city of New York, where he edited several periodicals, and became a constant contributor to others. In 1839 he published a novel entitled "The Adventures of Harry Franco, a Tale of the great Panic." Four years later his "Haunted Merchant" appeared, and in 1847 "The Trippings of Tom Pepper, or the Results of Romancing." In 1844 he commenced the "Broadway Journal," of which in the following year Edgar A. Poe became his associate editor. He was an editor of "Putnam's Magazine" from 1853 to 1856, in connection with George William Curtis and Parke Godwin, and also of the new series of the magazine in 1869. He was for some years one of the editors of the "New York Times," and is now (1873) one of the editors of the "Brooklyn Union."

BRIIGGS, Henry Perronet, an English painter, born in 1793, died in London in January, 1844. He first exhibited portraits in the royal acad-

emy in 1814, and in 1818 appeared as a historical painter. His best known works are "Othello relating his Adventures to Desdemona," and the "First Interview between the Spaniards and Peruvians."

BRIGHAM, Amariah, an American physician, born at New Marlborough, Berkshire co., Mass., Dec. 26, 1798, died at Utica, N. Y., Sept. 8, 1849. He commenced the practice of medicine in 1821, resided successively in Enfield and Greenfield, Mass., and in Hartford, Conn., and spent a year in European travel and study. In 1837 he delivered a course of lectures before the college of physicians and surgeons at New York. In 1840 he was appointed superintendent of the retreat for the insane at Hartford, and in 1842 of the New York state lunatic asylum at Utica. Here he had the personal care and supervision of 450 or 500 patients, besides which he delivered popular lectures on the treatment of the insane, and established a "Journal of Insanity." He published in 1832 a small work on "Asiatic Cholera," and soon afterward a treatise on "Mental Cultivation and Excitement;" in 1836, "The Influence of Religion upon the Health and Physical Welfare of Mankind;" in 1840, "The Anatomy, Physiology, and Pathology of the Brain;" and in 1849, a small volume of aphorisms and maxims for the use of those who had been under his care, under the title of the "Asylum Souvenir."

BRIGHAMIA (Gray), a curious genus of plants, of the family *lobeliaceæ*, discovered in the Hawaiian Islands, and named for William T. Brigham of Boston, Mass. In *B. insignis* the co-

Brighamia.

rolla is showy, white with a tinge of cream color; the long slender tube (4 inches) slightly incurved; lobes 5, about 1 inch long, vulvate in æstivation; stamens united in a column around the pistil and adnate to the lower half of the calyx tube; stigma 2-lobed, naked; ovary 2-celled; leaves obovate, about 6 or 8

inches long, clustered in a head at the summit of the column or stem. The flowers, which are abundant and last for several months, are sweet-scented. The plant has been cultivated in England, and makes a very ornamental appearance in conservatories. The juice is not milky as in most of the arborescent *lobeliaceæ*, and is reputed a remedy for skin diseases applied externally.

BRIGHT, Jesse D., an American senator, born at Norwich, Chenango co., N. Y., Dec. 18, 1812. He settled in Indiana, where he practised law, and held several offices, among which were those of state senator and lieutenant governor. He was chosen United States senator in 1845, and reelected for two successive terms. He was a strong adherent of the democratic party. Early in 1862 he was charged with disloyalty, the principal evidence being that on the 1st of March, 1861, after the organization of the confederate government, he wrote a letter addressed to "Jefferson Davis, president of the Confederate States," recommending to him a person who was desirous of furnishing arms. For this he was, by a vote of 82 to 14, expelled the senate, Feb. 2, 1862. He afterward settled in Kentucky.

BRIGHT, John, an English statesman, born at Greenbank, near Rochdale, Lancashire, Nov. 16, 1811. He is a member of the society of Friends, and head of a firm of cotton spinners and manufacturers in Rochdale. When the anti-corn-law association was formed in 1838, he entered heartily into its plans, coöperating with Mr. Cobden, and the two became the leading spirits in the league. In 1843 he was chosen member of parliament for Durham, took an active part in the measures for free trade, and had much to do with the bill of 1846 for the immediate modification of the corn laws, and their total repeal at the end of three years, or on Feb. 1, 1849. In 1847, and again in 1852, he was returned to parliament from Manchester. In 1854 he sanctioned the sending a deputation of Friends to dissuade the czar from entering upon hostilities with Turkey, and also deprecated the policy of England in taking part in the war. In 1857 his opposition to the war with China rendered him unpopular with his constituents, and he was defeated in Manchester by a large majority. He was, however, returned for Birmingham, and vigorously urged the passage of a vote of censure against the Palmerston administration for introducing the foreign conspiracy bill, in consequence of which the ministry resigned, Feb. 20, 1858. Shortly afterward he made a speech in favor of the reduction of the British military establishment, and condemning the policy of Asiatic conquest. In 1860 he took a leading part in bringing about the commercial treaty with France. During the American civil war he was a firm friend of the Union, and supported its cause both in and out of parliament. In 1865 he entered upon the agitation in favor of the extension of the elec-

tive franchise, which finally resulted in the passage of the reform bill of Aug. 15, 1867. He also urged the necessity of reform in Ireland, and the disestablishment of the Irish church, a bill for which was introduced into the house of commons March 1, and passed July 26, 1869. At the parliamentary election of 1868 a large majority of liberals were returned; the Disraeli administration resigned Dec. 2, and in the Gladstone ministry which succeeded it Mr. Bright became president of the board of trade, being the first Quaker who ever held a seat in the British cabinet. In consequence of the failure of his health, he resigned his seat in the cabinet Dec. 20, 1870. In 1872, having partially recovered, he resumed his place in parliament, but has not since been able to take any prominent part in public business. Mr. Bright's eloquence, energy, probity, and uniform adherence to principle, have placed him at the head of the liberal party in England. A collection of his "Speeches on Questions of Public Interest" has been published (2 vols., London, 1868).

BRIGHT, Richard, an English physician, born at Bristol in 1789, died Dec. 15, 1858. He took his medical degree at the university of Edinburgh in 1812, and afterward settled in London, where he practised with great success, and became licentiate of the royal college of physicians, and physician to Guy's hospital. He sought especially to trace the connection between morbid symptoms and alterations in structure of the internal organs; and in this way he discovered that the dropsical effusions and albuminous condition of the urine, present in the disease which bears his name, were dependent on a peculiar degeneration of the substance of the kidney. He wrote on morbid anatomy, on diseases of the brain, on abdominal tumors, and other similar subjects. His publications illustrating disease of the kidney appeared in 1836, 1839, and 1840.

BRIGHTON, a town of Middlesex co., Mass., on the Boston and Albany railroad, 4 m. W. of Boston; pop. in 1870, 4,957. It contains the principal cattle market of New England. There are 84 slaughter houses, employing 122 hands, and slaughtering annually 25,088 cattle, 170,517 swine, 23,781 sheep, and 1,200 calves. It also contains a planing mill, and manufactories of cordage, candles, oil, varnish, neatsfoot oil, bone, and glue stock.

BRIGHTON (formerly **BRIGHTHELMSTONE**), a watering place and parliamentary borough of England, in the county of Sussex, on the English channel, 51 m. S. of London by the London, Brighton, and South Coast railway; pop. in 1871, 90,013. It extends for more than 8 m. along the coast from Kemptown on the east to Hove on the west. The eastern half of the town stands on the ridge of high chalk cliffs which stretch away to Beachy Head; the western half is seated on a low pebbly beach, and is sheltered by Selsea Bill. The foundation of its prosperity was chiefly laid in the

middle of the 18th century, by Dr. Richard Russell, whose work on the use of sea water attracted much public attention. Its celebrity as a fashionable watering place was due to the prince of Wales, afterward George IV., who made it his place of residence, and commenced in 1784 the erection of the pavilion, which was completed three years afterward. The town subsequently purchased it from the crown for the sum of £53,000, and threw it and the pleasure grounds attached to it open to the public. The chain pier was erected by a joint stock company in 1822-'3, at an expense of £30,000. It is 1,134 ft. long, and extends into the sea 1,014 ft. Another pier 1,115 ft. long was completed in 1867. The east side of Brighton is protected by a sea wall 60 ft. high and 23 ft. thick at the base. In the western quarter is a battery, consisting of six 42-pounders, erected in 1793. On the eastern side is the Queen's park, and on the western a chalybeate

There are 5 banks and 6 newspapers in the town. The coasting and foreign trade is transacted at Shoreham, 7 m. W. There are about 100 fishing boats, manned by 500 men. Mackerel, herrings, soles, brill, and turbot most abound; mullet and whiting are also met with. BRIGHTHELMSTONE is mentioned in "Domesday Book." It has frequently suffered from hostile invasion. The French plundered and burnt it in 1518. During the reigns of Henry VIII. and Elizabeth fortifications were erected to protect it. In the 17th century it contained 600 families, mostly engaged in fishing.

BRIGIDA, Bridget, or Bright, Saint, born in Sweden in 1302, died in Rome, July 23, 1373. She is thought to have been the daughter of Birger, prince of the royal blood of Sweden, and of Ingeburgis, a descendant of the Gothic kings. At the age of 16 she was given in marriage to the councillor Ulpho or Ulf Gudmarson, by whom she had eight children, the youngest of

whom is honored in the Roman calendar by the name of St. Catharine of Sweden. After the birth of these children the parents took a vow of continence, built a charity hospital which they served in person, and made a pilgrimage to Santiago de Compostella, on returning from which Ulpho resolved to enter the Cistercian monastery of Alvastre. He died in 1344. Brigida now divided the estate among her children, and built a large monastery at Wadstena, in which she placed 25 monks and 60 nuns, prescribing for them the rule of St.

Brighton.

spring. There are 25 churches and chapels belonging to the established church, and 30 other places of worship. Its institutions of learning are numerous. The Brighton college, founded in 1847 for the sons of the middle classes, has a more modern course of studies than the other great English schools. The benevolent institutions of Brighton are almost as numerous as its schools. Foremost stands the Sussex county hospital, established in 1828, and since thrice enlarged. The town hall is a large building. Fairs are held near the town on Holy Thursday and Sept. 4. There are a theatre, an assembly room, and two club houses. The literary societies are the royal Brighton scientific and literary institution, the Brighton Athenæum, and the Brighton workingmen's institute. A great marine aquarium was opened in August, 1872. There is every species of bathing establishments, and a good supply of fresh water and gas. The only manufacture is that of wooden wares.

Augustine. Here she spent two years in close seclusion, and then set out for Rome. After founding in that city an asylum for pilgrims and Swedish students, she went to Jerusalem, visited the holy places, and then returned to Rome. She was canonized by Boniface IX. in 1391, and Oct. 8 was appointed as her festival. In the church of Rome St. Brigida is best known by her revelations, chiefly concerning the passion of Jesus Christ, and events which were to happen in certain kingdoms. They were written after her narration partly by her confessor Peter, a Swedish Cistercian monk, partly by a Spaniard called Alfonso the hermit. Gerson attacked them with great severity; but the council of Basel gave them its approbation after they had been thoroughly examined by John de Turrecremata. Among her other works are a discourse in praise of the blessed Virgin, and a series of prayers on the sufferings and love of Christ.

BRIGITTINS, or *Order of our Saviour*, a branch of the Augustinians, founded about the year 1344 by St. Brigida of Sweden, and approved by Urban V. in 1370. It owes its origin to the monastery built by Brigida at Wadstena, near Linköping, in Sweden. It embraces both monks and nuns, who occupy contiguous buildings, and celebrate the divine office in the same church, but never see each other. The prioress is superior in temporal concerns, but spiritual matters are managed by the monks. All the houses of the order are subject to the bishop of the diocese, and no new one can be founded without express permission of the pope. The number of monks in each monastery was fixed by the rule at 25, that of nuns at 60; but this regulation was not always strictly enforced. Denmark, Norway, the Netherlands, Germany, Portugal, and several other countries had convents of this order, most of which, including the parent house at Wadstena, were destroyed at the reformation. The only house of the order in England was the rich institution known as Sion house, founded by Henry V. on the Thames, 10 m. from London. It was suppressed by Henry VIII., restored by Queen Mary, and again dissolved under Elizabeth. The monks of this order are now extinct, but a few convents for nuns existed in 1860 in Bavaria, Poland, Holland, and England.

BRIGNOLES, a town of Provence, France, in the department of Var, on the Calami, 21 m. N. N. E. of Toulon; pop. in 1866, 5,945. It is well built, and contains several squares planted and adorned with fountains, a public library, a normal school, an ecclesiastical school, and manufactories of silk, cloth, hardware, soaps, and of other articles. A good trade is carried on in wines, olive oil, liqueurs, and dried fruits; the prunes of Brignoles, produced in the country around Digne, enjoy a high reputation.

BRIHUEGA, a town of New Castile, Spain, in the province and 19 m. N. E. of the city of Guadalajara, on the Tajüña; pop. about 4,500. It was the scene of a decisive victory gained by the French, under the duke de Vendôme, over the allied forces, under Lord Stanhope, in 1710. A branch establishment of the royal cloth manufactory of Guadalajara occupies a splendid edifice built under the reigns of Ferdinand VI. and Charles III. A considerable trade in cloth and woollen goods is carried on.

BRIL, Paul, a Flemish painter, born at Antwerp in 1556, died in Rome in 1626. He aided his brother Matthew in decorating the Vatican, and executed some important works for the Sistine chapel. Some of his landscapes contain figures by Annibale Carracci. His finest composition is a landscape in the Vatican.

BRILLAT-SAVARIN, Anthelme, a French author and magistrate, born at Bellay, April 1, 1755, died in Paris, Feb. 2, 1826. He was a deputy to the states general in 1789, a judge of the court of cassation in 1792, and mayor of Bellay in 1793, in which year he fled to Switzerland and the United States to escape from the revo-

lutionary tribunal, and resided nearly three years in New York, where he supported himself by teaching French and by performing in the orchestra of a theatre. He returned to France in 1796, and during the consulate again became a judge of the court of cassation, which position he held till his death. He is known to literature by his anonymous writings on political economy, and on the archæology of the department of Ain, also by a work on duels; but chiefly by his famous book on gastronomy, entitled *Physiologie du goût*, published in 1825, which has been translated into English and several other languages.

BRINDISI (anc. *Brundisium* or *Brundisium*), a seaport of Italy, on the N. E. coast of the province of Terra d'Otranto, lying at the head of a deep and sheltered harbor of the Adriatic between the promontories Perno and Cavallo, in lat. 40° 38' N., lon. 18° E., 44 m. E. N. E. of Taranto; pop. about 12,000. The town has comparatively few objects of interest, its castle, called Forte di Terra, being the most noteworthy building of the place. This is a strong and well placed fortress, with immense round towers, and is the most conspicuous object in every view of the city. The cathedral, a large Norman structure, has little architectural beauty, and its walls have been much injured by earthquakes. Near it stands an ancient marble column about 50 ft. high, probably once a portion of a temple. The Appian way terminated at Brindisi. There is a public library in the town, and a valuable collection of ancient coins. Improvements are going on in the harbor, which has greatly deteriorated in value since the Roman times, in part on account of dikes erected by Cæsar and intended to add to the safety of the port; instead of doing so, they aided the accumulation of sand, and narrowed the entrance, to the great detriment of the inner bay. It is expected that the measures now in progress will restore the ancient value of the roadstead, secure a great depth of water along the piers, and materially advance the prosperity of the town. The importance and prosperity of Brindisi have of late years been greatly increased by the completion of the railway extending along the eastern coast from northern Italy. Thus connected with all the railways of the continent, it has been selected as the place of embarkation for the mails to the East. Steamers carrying these mails and passengers ply between Brindisi and Alexandria, connecting with the regular mail steamers of the Peninsular and Oriental steamship company. Letters for India and all the East can thus be posted at London some days after the departure of the company's vessels from England, and still overtake them at Alexandria.—According to ancient tradition, Brundisium was founded by Orestans in a very remote time. It flourished as an independent city, governed for some time by princes of its own people. In 267 B. C. it was taken by the Romans. It

now gained the greatest importance as a commercial city, and its excellent harbor, near the narrow extremity of the Adriatic, caused it to be selected for the principal Roman naval station. Hannibal made an unsuccessful attempt to capture it. The chief fleets sent out for eastern conquest set sail from its harbor. Sulla landed at Brundisium when he returned in 83 B. C. from the Mithridatic war, and accorded the city many privileges for its kind

reception of him. Cæsar unsuccessfully endeavored to blockade Pompey and a part of his fleet in the bay before the city. Brundisium was again besieged by Antony in 40 B. C., but his reconciliation with Octavius prevented his pushing the siege to its end. Cicero landed here when he returned from exile in 57 B. C.; Horace visited the city in company with Mæcenas and Cocceius; Virgil died there in 19 B. C. After the fall of the Roman empire,

Castle of Brindisi.

Brindisi, after being at different times under the dominion of Goths, Saracens, and Greeks, fell into the hands of the Normans, and under their rule formed an important port of embarkation for the crusaders; but it soon lost its commercial prosperity. Louis of Hungary and Louis of Anjou each sacked the town in the 14th century, and in the 15th it was nearly destroyed by an earthquake. Frederick II. began the castle, and Charles V. completed it; but Brindisi even in his time had lost its prominence as a point either of attack or defence; and until the present century it remained an entirely insignificant seaport.

BRINDLEY, James, an English mechanic and engineer, born in Derbyshire in 1716, died at Turnhurst, Sept. 27, 1772. He was apprenticed to a millwright at the age of 17. After entering upon business he devised in 1752 an improved water engine for draining the coal mines at Clifton. In 1755 he built the machinery for a silk mill at Congleton. His reputation recommended him to the duke of Bridgewater, who employed him to construct a canal from his estate at Worsley across the river Irwell to Manchester; in 1761 he completed this watercourse, the first of the kind in England; it had no locks, and was in some parts a subterraneous tunnel and in others an elevated aqueduct. He revived the idea of canal communication across the country by uniting the rivers Mersey and Trent, and tunnelled the Harecastle hill, which had before been deemed an insurmountable obstacle. This tunnel is 2,280 yards in length, and 70 yards below the surface. It was begun in 1766, and finished after Brindley's death by his brother-in-law, Mr. Henshall, in 1777. He superintended the construction of the Coventry and Oxford canals, by means of which, together with the Mersey

and Trent canal, he connected the Thames, Humber, Severn, and Mersey. His education was very meagre. It was his custom when perplexed with any extraordinary difficulty to retire to bed, and lie there sometimes for two or three days till his plan was clear.

BRINE, the salt water naturally produced in many parts of the world beneath the surface of the earth, which is more or less saturated with chloride of sodium or common salt, and which flows out in springs or is pumped up for the use of the salt manufactories.—Brine is also the artificial saline solution used for preserving meats. By a paper communicated to the imperial academy of medicine of France, it appears that brine thus used acquires poisonous properties in a few months, so that its use with food continued for some time may produce fatal effects. The symptoms are first noticed in the effect of the poison upon the nervous system. Tremblings, convulsions, and loss of sensation are caused. The secretions of the skin and kidneys are also increased, and violent congestion and inflammation of the intestines ensue. The council of health in Paris, after examining into this subject, recommend that "in all cases brine preserved too long, or in contact with rancid meat, should not be employed, except with the greatest care, and after it has been purified by skimming all the scum which forms on the surface." The salt pickle can be removed from brine by a process termed *dialysis*, and the juice then has the property of fresh soup. It is proposed in this way to make use of the extract of meat contained in all brines which have not been in contact with rancid meat.

BRINKMANN, Karl Gustaf, a Swedish diplomatist and poet, born Feb. 24, 1764, died in Stockholm, Jan. 10, 1848. He studied in Ger-

many, and was in the diplomatic service from 1792 to 1810. The university of Upsal, to which he presented his library, made him doctor, and he was also made a baron and a member of the academy. His first poems were published in Leipsic (2 vols., 1789), under the name of Selmar; his *Philosophische Ansichten und Gedichte* appeared anonymously in Berlin (1801); and his poem *Die Welt des Genius* (1821) received the first prize of the academy. He was erroneously regarded as the author of K. L. von Woltmann's anonymous *Memoiren des Freiherrn von S—a* (3 vols., Prague, 1815).

BRINVILLIERS, Marie Marguerite d'Aubray, marchioness de, a French woman, convicted of poisoning her father, her brothers, and many others, executed at Paris, July 16, 1676. She was highly educated, and moved in the best French society. Her father was Dreux d'Aubray, a prominent public officer of Paris. In 1651 she married the marquis de Brinvilliers. Shortly after the marriage she fell in love with one of his friends, an adventurer named Gaudin de Sainte-Croix. Her husband did not interfere, but her father caused the arrest of Gaudin, who was incarcerated in the Bastille. Having there been taught by an Italian named Exili the preparation and application of a peculiar kind of poison, he became the instructor of the marchioness, who initiated her husband into the secret. The marquis having ruined himself by extravagance, the death of his wife's family was resolved upon, that they might obtain the property. He prepared the poison, and she experimented with it upon the sick in the Paris hospital, upon her guests, and upon her chamber maid. She made eight unsuccessful attempts upon her father before causing his death. She next poisoned her two brothers, and then attempted the death of her husband, who was saved by an antidote. Her paramour died of the effects of the poison while he was preparing it; a box was found in his house containing the poison and her love letters and other conclusive evidences of her crime, and she left Paris. Lachaussée, a servant who had assisted her in poisoning her brothers, put in a claim upon the effects of Sainte-Croix for wages due him. Being suspected, he was arrested and sentenced to death. Before his execution he made a full confession. Madame Brinvilliers, who had taken refuge in a convent at Liège, was arrested by a policeman, who gained access to her cell under the garb of a priest, and to her confidence under the character of a lover. He also secured her papers, among which one was found intended to be read after her death, in which she confessed that she had set fire to a house and poisoned her father, her brothers, one of her children, and herself. This paper was put in as evidence at the trial. On her refusing to admit its truth, she was taken to the torture room, when she confessed not only the crimes enumerated in the paper, but others which the government withheld from

public knowledge. Madame de Sévigné in her letters gives a graphic account of her execution. The poison she used was *aqua tofana*.

BRION, Luis, admiral of Colombia, born at Curaçoa, July 6, 1782, died Sept. 20, 1821. He was sent at an early age to Holland to receive his education, his father being a native of that country; he entered the Dutch army, and afterward visited the United States, where he studied navigation. Upon the death of his father he bought a vessel, made several voyages, established a mercantile house at Curaçoa, and in 1811 was appointed captain of a frigate in the service of the republic and state of Caraccas. At his own expense he fitted out a fleet of vessels, and attacked the Spanish forces at the island of Margarita, where he gained a signal victory. Brion distinguished himself at the conquest of Guiana, and also at Santa Marta and Cartagena. The latter part of his life was rendered unhappy by a misunderstanding with Bolivar, which so preyed upon his mind that he became ill, and leaving the squadron returned to Curaçoa, and soon died in poverty.

BRIOUDE, a town of Auvergne, France, in the department of Haute-Loire, near the left bank of the Allier, on the site of the ancient town of Brivas, 29 m. N. W. of Puy; pop. in 1866, 4,982. The old bridge at La Vieille Brioude, long celebrated as being the widest in span of any known, fell down in 1822. In the 16th century many of the inhabitants of Brioude rose in favor of Protestantism, but were subdued by the Roman Catholic party. Lafayette was born near this place, at Chadagnac. A considerable traffic in grain, hemp, and wine is carried on. The principal buildings are the college and the church of St. Julian. There is also a small public library. The railway from Clermont to Le Puy passes through it.

BRISACH. See BREISACH.

BRISBANE. I. A N. E. county of the colony of New South Wales, Australia, bordered on the S. by Hunter and Goulbourn rivers, and on the N. by the Liverpool mountains; area, 2,344 sq. m.; pop. in 1866, about 1,400. It consists chiefly of table land, diversified by a few plains and some high peaks, one of which, called the Burning mountain, or Mount Wingen, is in a state of combustion. The burning portion is from 1,400 to 1,500 feet above the sea. In 1866 there were 3,500 acres of land under cultivation, chiefly in wheat. There were 5,866 horses, 29,154 cattle, and 175,786 sheep. The principal towns are Murrumbidgee and Scone. II. A town of Australia, capital of Queensland and of Stanley county, situated on the river Brisbane, about 25 m. from its entrance into Moreton bay, and 440 m. N. N. E. of Sydney; pop. in 1871, 19,418, of whom 15,029 belonged to the city proper and the remainder to the suburbs. The town is divided into four parts, North and South Brisbane, Kangaroo Point, and Fortitude Valley. The two former are connected by an iron bridge. It is the seat of a Roman Catholic and an Anglican bishop, and has a

mechanics' institute, school of arts, general hospital, and botanical gardens which are laid out with great taste and excellently kept. There were published in 1871 one daily newspaper, two tri-weeklies, one weekly, and one monthly. Steamers run to Sydney, and to the northern ports; there is also regular communication with London by sailing vessels. Owing to the bar at the mouth of the river, only vessels of a limited size can come up to the city.

BRISSON, Mathurin Jacques, a French savant, born at Fontenay-le-Comte, April 30, 1723, died at Boissy, near Versailles, June 23, 1806. He was instructor to the children of the royal family of France in physics and natural history. He was also royal censor, member of the academy of sciences and of the institute, and succeeded Nollet in the chair of natural philosophy at the college of Navarre. He translated Priestley's work on electricity, although he opposed his theories, and still more those of Franklin. The best of his writings are on specific gravity and on ornithology. Buffon quotes frequently from the latter work.

BRISSOT, Jean Pierre, a Girondist leader, surnamed De Warville after the village of Ouarville, near Chartres, where he was born, Jan. 14, 1754, died by the guillotine, Oct. 31, 1793. He had abandoned the law for literature, when a seditious publication, wrongly imputed to him, caused him to be imprisoned. Afterward he repaired to London, where he conducted a French journal; he then went to the United States, where he wrote against slavery, having previously been one of the original founders of *la société des amis des noirs*. Returning to France on the outbreak of the revolution of 1789, he became the editor of *Le Patriote Français*, and a member of the commune of Paris; and having labored assiduously, and with uncommon ability, in the interest of the revolution, he was chosen member of the legislative assembly, where he soon took a conspicuous position as a leader of the Girondists, who from him were frequently called Brissotins. After the king's flight, he put himself at the head of those who demanded his deposition, and eventually taking his seat in the convention as a representative of the department of Eure-et-Loire, he was instrumental in bringing about the declaration of war against Austria, England, and Holland. He made himself obnoxious to Robespierre and his party by opposing the immediate execution of the king, though he voted for his death, and was finally doomed to die on the same day with 20 of his political associates. (See GIRONDISTS.) He was the author of a great number of works and memoirs, chiefly on law, politics, and metaphysics. His work on the United States (1791) was translated into English, German, and Dutch. His biography was published in 4 vols. (Paris, 1829-'32).

BRISTED. I. John, an Episcopal clergyman and author, born in Dorsetshire, England, in 1778, died at Bristol, R. I., Feb. 23, 1855. He was educated at Winchester, studied law, came

to America in 1806, and practised in New York. In 1820 he married a daughter of John Jacob Astor. Having studied divinity under Bishop Griswold, he succeeded him in 1829 as rector of the church of St. Michael at Bristol, which office he discharged till 1843. Among his works are: "A Pedestrian Tour through part of the Highlands of Scotland" (2 vols. 8vo, London, 1804); "Critical and Philosophical Essays" (1804); "Edward and Anna," a novel (1805); "The Resources of the United States" (New York, 1818); and "Thoughts on the Anglican and Anglo-American Churches" (1822). **II. Charles Astor**, an American author, son of the preceding, born in New York in 1820. Having completed the course at Yale college, he entered in 1840 the university of Cambridge, England, and graduated at Trinity college in 1845, with high honor as a classical scholar. He has since passed many years in Europe, has written much for newspapers and magazines, usually under the signature of Carl Benson, and has published several books, among which are: "Selections from Catullus," with notes (1849); "Letter to Hon. Horace Mann," being a reply to attacks made upon Stephen Girard and John Jacob Astor; "The Upper Ten Thousand of New York" (1852); "Five Years in an English University" (1852; new ed., 1873); and "The Interference Theory of Government" (1867). He was one of the original trustees of the Astor library.

BRISTOL. I. A S. E. county of Massachusetts, bounded S. E. by Buzzard's bay, and W. by Rhode Island, and drained by Taunton and Pawtucket rivers; area, 517 sq. m.; pop. in 1870, 102,886. It is diversified by many irregularities of surface. Its seacoast, about 18 m. in extent, is indented by numerous bays and good harbors. Iron ore is found in large quantities. Manufacturing is extensively carried on, particularly at Fall River. New Bedford is the chief whaling port of the country. The Boston and Providence, New Bedford and Taunton, Taunton branch, and Fall River railroads pass through the county. There are 27 cotton mills, 2 calico print works, 2 woollen mills, 4 shoddy mills, 6 brass foundries, 13 flour mills, 6 tanneries, 54 saw mills, 3 manufactories of spool cotton, 10 rolling and splitting mills, and numerous other manufactories. The chief productions in 1870 were 7,928 bushels of rye, 82,256 of Indian corn, 40,003 of oats, 237,675 of potatoes, 27,091 tons of hay, and 223,986 lbs. of butter. There were 2,668 horses, 5,671 milch cows, 3,908 other cattle, 2,281 sheep, and 3,773 swine. Capitals, New Bedford and Taunton. **II.** An E. county of Rhode Island; area, 25 sq. m.; pop. in 1870, 9,421. Mount Hope and Narragansett bays bound it E., S., and W. The surface is uneven, and presents a variety of beautiful scenery. The soil is very fertile. A railroad from Bristol to Providence passes through the county, and another extends from Fall River to Warren. The chief productions in 1870 were 13,521 bushels of Indian

corn, 5,934 of oats, 34,996 of potatoes, and 2,551 tons of hay. There were 399 horses, 664 milch cows, 571 other cattle, 473 sheep, and 648 swine. Capital, Bristol.

BRISTOL, a town, port of entry, and the capital of Bristol co., R. I., 16 m. by rail S. E. of Providence, and 11 m. N. of Newport; pop. in 1870, 5,802. It is pleasantly situated on a peninsula stretching out toward the south, between Narragansett bay on the west and Mount Hope bay on the east. The town is 5 m. long and 3 m. broad, and has an area of 12 sq. m. It includes Mount Hope, a beautiful eminence 300 ft. above water, noted for the fine view from its summit, and interesting as the ancient residence of King Philip, who was killed here in 1676. The soil is very fertile, and a considerable portion of the inhabitants are engaged in raising onions and other market vegetables. The village is a place of summer resort, and contains a newspaper office, several churches, banks, manufactories, and good schools. During the revolutionary war it was bombarded by the British, and a large part of it burned to the ground. A railroad connects it with Providence, and steamers from Fall River to the latter city also stop here. For the year ending June 30, 1871, the imports from foreign countries into the district (which also includes Warren) amounted to \$37,161; exports, \$30,329. There were registered 22 vessels with a tonnage of 2,139.

BRISTOL, a post borough, and formerly the capital of Bucks co., Penn., on the right bank of the Delaware river, nearly opposite Burlington, N. J., and about 19 m. above Philadelphia; pop. in 1870, 3,269. It is a pleasant, neat-looking town, with several churches, a bank, a flour mill, a mineral spring, and abundant means of communication with the chief cities of the Union. A quarterly periodical is published here. A railroad from New York to Philadelphia passes through it, a line of steamboats connects it with Philadelphia, and the Delaware branch of the Pennsylvania canal terminates here in a large basin communicating with the river.

BRISTOL, a seaport and city of England, on the borders of Gloucestershire and Somersetshire, but independent of both, situated at the confluence of the Avon and Frome, 8 m. from their entrance into the estuary of the Severn, the head of Bristol channel, 12 m. N. W. of Bath, and 118 m. W. of London; pop. in 1871, 182,524. The Avon being navigable for large vessels up to this point, gives to Bristol great commercial advantages, which have been further improved by dock accommodation. The British docks, which were originally formed in the reign of George III., at an expense of £600,000, were purchased in 1847 by the corporation, and are now the property of the city. Bristol was long the second city of the kingdom, and from 1750 to 1757 the average net receipts of the customs there amounted to £155,189 sterling, while those of Liverpool

were £51,136. But in the latter part of that century the advantages of Liverpool in natural position, and her vicinity to the northern coal, iron, and manufacturing districts, rapidly secured her the superiority; and the West India trade, which formerly belonged exclusively to Bristol, has been in the present century transferred to London, since the completion of the West India docks. The growth of railway communication has also partly deprived Bristol of its long standing character as the commercial depot of the west of England. It is still the great point of shipment between the south of Ireland and England. Numerous manufactures are carried on, among which are refined sugar, brass and copper wares, soap, glass, chain cables, anchors, machinery, tobacco, earthenware, floor cloth, wire, pins, shot, sheet lead, zinc, saltpetre, tin pipes, hats, spirits, malt liquors, and soda. There is a large cotton factory, employing 1,700 hands, and other manufacturing establishments are on a large scale. There are seven banking establishments, including a branch of the bank of England, a savings bank, and a gas company. The tides in the Bristol channel rise 48 ft. at springs and 23 at neaps, and at the floating harbor often to 30 ft., so that vessels of the largest draught come to the city. To obviate the risk of damage at the rise, and of grounding at low tide, a floating harbor or wet dock has been constructed, by changing the bed of the river Avon for a length of 3 m. There is a quay of a mile in length, and a number of basins. Five bridges connect the opposite sides of the floating harbor and river. There are also graving docks and ship yards, suitable for vessels of the largest size. The Great Western and Great Britain, besides many other large steamers,

Church of St. Mary Redcliff.

were built at this port. Three railways, the Bristol and Gloucester, the Great Western, and the Bristol and Exeter, have termini in this

city. There are numerous interesting monuments of antiquity, among which the church of St. Mary Redcliff is conspicuous both for its beauty and for Chatterton's connection with it. The cathedral has a fine Norman gateway. Among the modern buildings are the council house, in the Italian style, the guildhall, in the

The Guildhall.

Tudor style, the Victoria rooms for concerts and exhibitions, the Bristol institution, with a fine gallery of art, and the bridewell prison, rebuilt after the riot of 1831. The Bristol library, founded in 1772, has 50,000 volumes. Clifton, a suburb of Bristol, is a noted watering place. (See CLIFTON.)—Bristol dates from before the Roman invasion, but did not become a place of strength and importance till after the Norman conquest. In the 12th and 13th centuries it was noted both for its trade and manufactures. By the enterprise of Bristol merchants some of the early expeditions for the extension of discovery in the western world were fitted out. Sebastian Cabot passed his early life in Bristol, and a Bristol ship first touched the American continent. Martin Frobisher brought one of the Esquimaux to Bristol in 1578. Hakluyt belonged to Bristol, and Newfoundland was colonized from Bristol. It figured in the wars of the roses, and was a commanding position during the war between Charles I. and the parliament. It was carried by storm by Prince Maurice and Prince Rupert in 1643, but after the defeat of Charles at Naseby was surrendered by Prince Rupert to Sir Thomas Fairfax, after a brief resistance. It was the scene of riots on account of local disputes in 1793, and of a disastrous riot in 1831, on occasion of a visit from Sir Charles Wetherell, an opponent of the reform bill.

BRISTOL BRICK, a sort of brick used for cleaning steel, manufactured for some years exclusively in Bristol, England. A small vein of the sand required for this purpose was found near Liverpool, but was soon exhausted. One of the owners or operatives, who had been concerned in the works at Bristol, visited the United States in 1820, where by accident he discovered that the same kind of sand which was used for the Bristol bricks might be procured at South Hampton, N. H. Since that period bricks fully equal to the imported article have been manufactured in this country.

BRISTOL CHANNEL, a body of water separating the southern portion of Wales and Monmouthshire in England from the counties of Devon and Somerset, and composed of the estuary of the river Severn and the broad arm of the sea into which that river empties. It may be said to extend from the mouth of the Bristol or lower Avon, where its width is about 5 m., to the Atlantic, into which it enters between Hartland point, in Devonshire, and St. Gowan's head, in Pembrokeshire, Wales. Its width between these capes is about 40 m. It is bounded by shores as irregular in outline as they are various in their general features, and the whole coast, but especially that on the north, is remarkably picturesque.

BRIT (*clupea minima*, Peck), a small species of herring, varying in length from one to four inches, found at some seasons of the year in immense numbers on the coast of New England; it serves as food for the bluefish and other predatory species. The back is nearly black, the upper part of the sides dark green, and the sides silvery with roseate and golden reflections; the lateral line is very high up, and the abdominal ridge is serrated; the lower jaw rather projects beyond the upper. It used to be very abundant in the bay of Fundy, but is rare there of late years; it is said to be frequently met with in the gulf of St. Lawrence, and is mentioned by De Kay in his "Fishes of New York." In the young specimens the dorsal ridge is a black line, and the space between this and the lateral line is light green, with small darker points. Its immense numbers might make it of value in some localities as a manure, and as a bait for other fish.

BRITAIN, or *Britannia*, an ancient name of the island of Great Britain. The first name given to the island by the earliest Greek writers whose works have come down to us was Albion, which is supposed to have been formed from the Celtic *alb* or *alp*, meaning according to some authorities white, according to others high, and applied to the island either from the white appearance of its chalky cliffs on the south, or from its northern mountains. The natives themselves are said to have called it Eilanban, "the white island," from which Albion could easily be formed. The origin of the word Britain is even more uncertain than that of Albion. Camden supposed it to be formed from *brit*, a Celtic word signifying painted, and that it therefore means the land of the painted people. Carte more probably derives it from Brydtrain, the name which the natives called themselves by, and which was easily latinized into Britain. The aboriginal or at least the earliest inhabitants of Britain were of Celtic origin and race, as is evident from the fact that nearly all the names of mountains, lakes, and rivers in the island are still descriptive and significant in the Celtic language. At a very early period, however, and before we have any authentic knowledge of Britain, its Celtic population seems to have been conquered and dis-

placed by Gothic tribes who at the time of Cæsar's invasion, when the history of Britain begins, occupied the S. E. part of the island, and had driven the Celts into the remoter and less accessible districts. Before the time of Cæsar, however, nothing is really known of Britain beyond some vague allusions by Herodotus and a statement by Aristotle that in the western ocean there were two large islands, Albion and Ierne, which were called Britannia. The Phœnicians and Carthaginians knew the island and traded with the natives for tin, but they have left no record of their knowledge of it. (See ENGLAND.)

BRITANNIA METAL, also called white metal, an alloy of 86 parts of tin, 10 of antimony, 3 of zinc, and 1 of copper. Its composition, however, is somewhat variable. Dr. Thomson gives the analysis of one specimen: tin, 85·72; antimony, 10·39; zinc, 2·91; copper, ·98=100. It is cast into ingots and rolled into thin sheets. It is an alloy of great use for the manufacture of domestic utensils, and is very generally employed as the base of articles designed to be plated with silver. It was first manufactured in England about 1770, by Jessop and Hancock.

BRITANNICUS, son of the emperor Claudius and Messalina, born in A. D. 42, in the second consulship of his father, died in 55. His original name was Claudius Tiberius Germanicus, but when the senate conferred the title of Britannicus on the emperor, the infant prince was allowed to participate in the honor, which henceforward became his distinctive appellation. After the death of his mother, and the marriage of his father with Agrippina, that unscrupulous woman prevailed on Claudius to set aside the claims of Britannicus to the throne, and to make her own son Nero his heir. After the accession of Nero, Agrippina, having quarrelled with him, threatened to present Britannicus to the legions, and Nero determined to rid himself of so dangerous a rival. A dose of poison was dissolved in a goblet of wine and handed to him at a banquet. He drank, and immediately expired. As his funeral passed to the Campus Martius a storm raged, and the rain, according to a somewhat doubtful statement in Dion Cassius, washed from his visage the paint with which it had been smeared, and exposed his swollen and blackened features.

BRITISH AMERICA, the whole of North America N. of the United States, with the exception of Alaska, the N. W. corner of the continent. The boundary line between British America and the United States was mainly determined by the conventions of 1889 and 1846; and finally, as to the disputed possession of the island of San Juan, in 1872, by the arbitration of the emperor of Germany. The extreme southern point of British America is on or near Middle island, in Lake Erie, lat. 41° 40' N. British America is bounded N. by the Arctic ocean, N. E. and E. by Baffin bay, Davis strait, and the Atlantic ocean, S. by the United States,

and W. and N. W. by the Pacific ocean and Alaska. The total area about 3,500,000 sq. m.; pop. 4,455,000. British America, as organized under regular governments, comprises the Dominion of Canada, Prince Edward Island, and Newfoundland. (See those titles.)

BRITISH BURMAH. See BURMAH, BRITISH.

BRITISH COLUMBIA, a province of the Dominion of Canada, on the Pacific coast, between lat. 48° 19' and 60° N., and lon. 118° and 186° W., bounded N. by the 60th parallel, E. by the Rocky mountains, which extend N. W. and S. E. from lon. 120° to 118° S. by the United States, and W. by the Pacific ocean and Alaska; area, including Vancouver and other islands, about 283,000 sq. m. The population, according to an enumeration made in the spring of 1871, consists of 8,576 white, 462 negroes, and 1,548 Chinese; total, 10,586, exclusive of Indians, estimated at 35,000 to 40,000, who subsist by fishing, hunting, and trapping fur-bearing animals. The coast line is deeply indented. Vancouver island extends from lat. 48° 19' to 50° 53' N., a distance of 278 m., along the southern portion of the mainland, from which it is separated by the gulf of Georgia, 90 m. in width. The N. entrance to the gulf is Johnston's strait, and the S. entrance is the strait of Juan de Fuca, which separates the S. shore of the island from the territory of the United States. Queen Charlotte islands, lying between lat. 52° and 54° N., and lon. 181° 25' and 184° W., are separated from the N. portion of the coast by Queen Charlotte sound. The country is generally mountainous, though the interior is much diversified. There are extensive tracts of arable land, and large sections suitable for grazing purposes. The E. portion is occupied by the Rocky mountains, the highest summits of which are Mt. Hooker, 15,700 ft., and Mt. Browne, 16,000 ft. The Cascade mountains, a continuation of the Sierra Nevada range of California, intersect the country from N. to S. about 100 m. from the coast. Contiguous to the coast is another lofty range extending N. into Alaska. Between Fraser and Thompson rivers is a large tract of level forest. The surface of Vancouver island is very mountainous and covered with forests of pine and cedar; it contains little agricultural land, but is supposed to be rich in minerals. The rivers are numerous and large, but their navigation is much interrupted by frequent rapids and falls. The Columbia rises in the vicinity of the Rocky mountains, in lat. 50° 30' N. and lon. 116° W., and flows N. W. to lat. 52° 10', when it takes a S. course to the United States. It is navigable as far as the head of Upper Arrow lake, lat. 50° 30'. Fraser river has its sources on the W. slope of the Rocky mountains, in lat. 52° 25' and lon. 118° 40', and after a N. W. course of about 160 m. to lat. 54° 30', turns abruptly and flows nearly due S. to lat. 49° 30', when it turns W. and flows to the gulf of Georgia near the United States border. It drains the E. slope of the Cascades and the W. slope

of the Rocky mountains. In a right line it is less than 500 m. long, but with its meanderings 800 m. The river is navigable for about 100 m. of its lower course, and about 80 m. midway between its source and mouth. The Fraser has several affluents, the chief of which are Thompson, Harrison, and Lilloet rivers. The first named rises in the Rocky mountains, flows W., and joins the Fraser in lat. 50°. Peace river rises on the N. slope of the range which deflects the Fraser from its N. to S. course, and flows N., where it joins the Finlay. The Stikine and Simpson are also considerable rivers, in the north of the territory, flowing into the Pacific. There are numerous lakes, the largest of which, the Upper and Lower Arrow, are connected with the Columbia river. Lake Okanagan has for its outlet the river of the same name. Pitt, Harrison, Lilloet, Anderson, Quesnelle, and Caribou lakes are connected with Fraser river. Some of these lakes are navigable. The open country around Lake Okanagan varies in height up to 1,500 ft. above the level of the sea; round Nicola lake up to 2,000 ft.; round Lake La Hache to over 2,500 ft. The plateau between Clinton and Bridge creeks has an elevation of from 3,500 to 4,000 ft. The climate is healthy, and generally milder than in the corresponding latitude eastward of the mountains. On the coast the winter is more humid than cold. The lakes are never wholly frozen, and travel is never impeded by the snow except in the mountain passes. All the harbors remain open throughout the winter except that of New Westminster, where the floating ice is dangerous to shipping from January to March. From the middle of October till March there is much rain, with high winds. Winds from the S. and S. E. bring rain, and from the N. and N. W. fair weather. The central and eastern districts have from their elevation a severer climate, and in the upper country the thermometer in winter sometimes indicates 40° below zero.—The soil of the valleys is generally fertile, but is subject to floods. The plateaus are barren, while the hillsides are generally covered with good timber. The districts fit for agricultural settlement are thus estimated: On Fraser and Thompson rivers, 60,000 sq. m.; sources of the upper Columbia, 20,000; Athabaska district, 50,000; Vancouver island, 16,000. The tract extending from Thompson river to the Rocky mountains is described as eminently suitable for colonization. It possesses abundance of timber and of bituminous coal, is diversified by hill and dale, watered by numerous streams and lakes, and has boundless pasturage. The soil, as elsewhere throughout the country, varies from a deep black vegetable loam to a light brown loamy earth, the hills supplying slate and building stone. The land on the lower course of Fraser river is also good, but it is covered almost entirely with dense forests. Wheat, oats, barley, Indian corn, peas, beans,

potatoes, turnips, carrots, &c., have been successfully raised; while garden produce, tomatoes, cucumbers, &c., ripen early. There is abundance of grass for cattle and flocks during the summer, and plenty of hay obtained for their support during the winter. Agriculture, however, is in a backward state. In the forests are found cedar, pine, fir, maple, hemlock, birch, poplar, willow, alder, and cottonwood trees, besides a variety of grasses and flowers. Sheep raising has been introduced with success. The country is rich in fur-bearing animals, chiefly black, brown, and grisly bears, lynx, marten, and beaver. It was formerly the richest fur district of the Hudson Bay company. Fish abound in the lakes and rivers; salmon are especially plentiful, and of four species, the largest being from 10 to 20 lbs. in weight. They proceed up Fraser river in countless numbers, till stopped by shallow water, few of them returning to the sea.—Although gold has been discovered in almost every part of the territory, and especially upon and E. of Fraser river, the fields which have been most extensively worked are in the Caribou district, which lies in the N. bend of Fraser river, about lat. 53° 20'. Gold is also found in the Thompson and many of its smaller tributaries, on the Peace, and also on Gold stream and Leech river in Vancouver island. The gold is mostly in grains, few large pieces or "nuggets" having been found. Mining operations have been limited mainly to alluvial deposits, quartz crushing not having been introduced. The Caribou mines have been worked without interruption since their discovery, but for some years have yielded less than \$1,500,000 per annum. The number of miners is about 2,000. According to the report of the commissioner of mines, the total amount of gold exported from the colony in 1869 was \$2,417,873, exclusive of about \$1,000,000 taken away by individuals. In 1870 it sank to \$1,002,717, and in 1871 to \$734,792, exclusive of what was taken away privately, about one third more. From 1862 to Sept. 20, 1871, the whole amount publicly exported was \$16,650,036. The tardy development of the mines is attributed to the want of a geological survey, which has now, however, been undertaken. Veins of silver have been discovered near Fort Hope and on Cherry creek near Shushwap lake, but are yet undeveloped. Nuggets of native silver have been found on Peace river, indicating the presence of extensive deposits in that region. Veins of copper and lead are numerous, and prospecting has been done on the former, but without satisfactory results. Rock crystals, cobalt, talc, and iron ore exist near Fraser river. Platinum, cinnabar, plumbago, and agate have also been found. Coal abounds in several localities. Beds of valuable bituminous coal have been profitably worked on Vancouver island, where the annual produce amounts to about 50,000 tons, of which about 20,000 tons were exported in 1869. It is about 10 per cent.

lighter than Welsh coal, and its consumption is so much more rapid. The anthracite contains 70 per cent. of carbon, and is of superior quality. A large area of the N. W. portion of the island is mainly of the bituminous coal formation. Similar beds exist also on Queen Charlotte island. The annual exportation of coal, chiefly to San Francisco, amounts to about \$200,000.—The chief port and commercial town is Victoria, the capital, on Vancouver island, containing about 4,000 inhabitants. New Westminster is on Fraser river, about 15 m. from its mouth, and has about 1,000 inhabitants. The other principal points are Langley, Fort Hope, Fort Yale, and Lilloet on Fraser river, and Douglas on Harrison lake. Most of these places are connected with the United States by telegraph. The exports are gold, coal, furs, spars, lumber, fish, fish oil, wool, and cranberries; the imports are provisions, clothing, furniture, and tools. Large numbers of spars, unequalled in length and quality, are exported. The exports of lumber amount to about \$120,000 annually. The aggregate value of imports which passed into the colony through the port of Victoria in 1869 was \$1,776,623, and of exports, including gold, \$719,203. In 1870 the exports, exclusive of gold, amounted to \$208,364. The entrances in 1869 were 864 vessels, of 199,634 tons, and the clearances 896 vessels, of 202,551 tons. The next year, 835 vessels of 173,209 tons entered, and 804 of 170,624 tons cleared. The total exports from British Columbia and Vancouver island to the United Kingdom amounted to £63,681 in 1867, £76,614 in 1868, £51,490 in 1869, £60,751 in 1870, and £76,644 in 1871. The chief articles of export in 1871 were train or blubber oil, to the value of £9,651; seal skins, £6,850; other skins and furs, £41,472; hewn wood and timber, £16,819; wool, £268; other articles, £1,584. The imports from Great Britain amounted to £103,206 in 1869, £73,581 in 1870, and £78,481 in 1871. The total revenue raised throughout the colony in 1869 amounted to \$530,470, and the expenditures to \$517,332.—British Columbia is represented in the parliament of the Dominion of Canada. The territorial officers are a governor, appointed by the English crown, a secretary, a commissioner of lands and public works, and a collector of customs. The law officers are two judges, an attorney general, a registrar, and a high sheriff. The legislative council consists of 15 members, 5 of whom are public officers, 5 are selected by the governor, and 5 are elected by the people subject to the approval of the governor. The elected assembly of Vancouver has been discontinued, and that island is represented in the legislative council of British Columbia. Four newspapers, of which two are daily, are published in the province, and there are three libraries with 4,000 volumes.—British Columbia, comprising the territories formerly known as New Caledonia, New Georgia, New Norfolk, and

New Cornwall, was prior to 1858 entirely under the control of the Hudson Bay company, whose trading posts were stationed at various points on the coast and in the interior. The discovery of gold in that year caused an influx of population and the formation of a colony. It is estimated that the number of immigrants in 1858, chiefly from California, was not less than 20,000. On the first influx, the governor of Vancouver island took prompt measures to secure to the British government the royalty of the minerals by imposing a license tax, and to maintain the Hudson Bay company's monopoly by forbidding the importation of goods other than through the company's agencies. He also forbade to foreign ships the navigation of Fraser river. By an act of parliament passed Aug. 2, 1858, British Columbia was created a distinct colonial government, comprising the territory as far N. as Simpson river and the Finlay branch of Peace river. In 1863 the N. boundary was extended from about lat. 56° to 60° N. The colony included all the adjacent islands except Vancouver, which was incorporated with British Columbia under one government in 1866. In 1871 British Columbia was admitted into the Dominion of Canada. The leading condition of the union was an agreement on the part of the Dominion government to construct a railroad connecting the Pacific coast with the eastern provinces. This railroad, the Canadian Pacific, is to be not less than 2,500, and may be 2,700 m. long, extending from Victoria to some point in the province of Ontario, possibly to Lake Nipissing, about 200 m. N. of Toronto. It is to be completed by 1881. It is expected to develop the valuable mineral districts of the province, and divert the China and Japan trade from its present channel.

BRITISH EMPIRE, a vast complex of states in various parts of the world, subject to the crown of England. Its different portions will be treated under their several names. We here present a condensed view of them all together:

IN EUROPE.—The *United Kingdom of Great Britain and Ireland*, with the adjacent islands in the British seas, including the Shetlands, Orkneys, Hebrides, Scillies, Man, the Channel islands, and the Isle of Wight; area 121,115 sq. m.; pop. in 1871, 81,317,108. Wales was incorporated into the kingdom of England in the reign of Edward I. Scotland, whose sovereign became king of England in 1603, long continued distinct for administrative and legislative purposes. It was fully joined to England by the act of union in 1707, by which the Scottish legislature was dissolved, and the Scotch were admitted to representation in the British houses of lords and commons. The Scotch still maintain their own peculiar laws, customs, and national church. Ireland was nominally annexed to the crown of England in 1172; but for centuries it resisted the invader, and can scarcely be said to have been subjugated until it was reduced by Cromwell. It was governed by its own parliament till 1800, when by an act of union it was united to England, and, like Scotland, admitted to the rights of representation both by peers and commoners in the British parliament. Its laws are essentially the same as those of England, though passed specially for Ireland. The Anglican church was imposed upon Ireland as a state church, with all the endowments of the ancient Catholic church, although less than one eighth of the population are members of its communion; but it was finally disestablished in 1871. *Heligoland*, a small island in the German ocean, inhabited chiefly by fishermen, taken from the Danes in 1807; area, 0·21 sq. m.; pop. in 1860, 3,173. *Gibraltar*, taken from the Spaniards in 1704, consisting of a lofty steep rock, bristling with guns, and

regularly fortified, and a small space of sloping ground at its foot on which stands its town; area, 2 sq. m.; pop. in 1871, 18,695. *Malba*, a strongly fortified naval and military station, with its dependency Gozo, taken from the French in 1800; area of both, 143 sq. m.; pop. in 1866, 189,502.

IN ASIA.—*British India* is divided into British possessions and native states more or less under the control of the British government. Since Aug. 2, 1858, all the territories heretofore under the government of the East India company have been vested in the crown, in the name of which all authority is exercised. The executive authority is vested in a governor general, who acts under the orders of the secretary of state for India, and also appoints various lieutenant governors and commissioners for the several presidencies and provinces. The provinces of Hyderabad, Mysore, and Coorg (47,661 sq. m., pop. 6,389,792) are under the direct administration of the governor general. The remainder is under the following functionaries: Lieutenant governor of Bengal, 239,591 sq. m., pop. 85,975,274; Lieutenant governor of Northwest Provinces, 88,875 sq. m., pop. 80,086,893; Lieutenant governor of the Punjab, 102,001 sq. m., pop. 17,596,752; chief commissioner of Oude, 24,060 sq. m., pop. 11,220,747; chief commissioner of Central Provinces, 54,162 sq. m., pop. 7,985,411; chief commissioner of British Burmah, 98,881 sq. m., pop. 2,463,484; governor of Madras, 141,746 sq. m., pop. 26,559,052; governor of Bombay, 87,639 sq. m., pop. 11,093,512; commissioner of Sind, 54,408 sq. m., pop. 1,795,594. Total area of British possessions in India, 968,929 sq. m., pop. 151,146,426. There are some 60 or 70 native chiefs and states under the control of the British government; area, 644,147 sq. m., pop. 46,245,988. Besides India, the British possessions in Asia include the islands of *Ceylon* and *Singapore*, *Hong Kong* in China, and a few small settlements, with a total population of about 2,800,000. Also *Aden*, a seaport at the mouth of the Red sea, pop. about 50,000.

IN AFRICA.—*Cape Colony*, extending from the Cape of Good Hope to the Orange river, taken from the Dutch in 1806; 200,610 sq. m., pop. 566,158. *Port Natal*, N. E. of Cape Colony, settled in 1833; 17,801 sq. m., pop. 269,862. *Sierra Leone*, settled in 1787, as a colony for slaves who had been released from their captors; 468 sq. m., pop. 55,874. *Gambia*, N. of Sierra Leone, settled in 1681; 21 sq. m., pop. in 1851, 6,989. The *Gold Coast Settlements*, comprising several forts and trading posts, of which Cape Coast Castle is the chief; 16,626 sq. m., pop. estimated at 400,000. *Mauritius*, and several small islands adjacent, lying in the Indian ocean, taken from the French in 1810; 708 sq. m., pop. 822,924. *St. Helena*, an island in the Atlantic, ceded by the Dutch in 1651; 47 sq. m., pop. 6,860. *Ascension*, an almost uninhabited rock N. of St. Helena.

IN AMERICA.—*Dominion of Canada*, comprising the former territorial divisions of Canada, New Brunswick, Nova Scotia, Hudson Bay territory, British Columbia, and Vancouver island; 8,481,779 sq. m., pop. 8,648,000. *Newfoundland*; 40,200 sq. m., pop. 146,536. *Prince Edward Island*; 2,173 sq. m., pop. 94,021. *The Bermudas*, in the Atlantic ocean, off the coast of the United States; 24 sq. m., pop. 11,796. *West India Islands*; 12,636 sq. m., pop. 1,023,708. *British Honduras*; 13,500 sq. m., pop. 25,635. *British Guiana*, taken from the French in 1808; 99,925 sq. m., pop. 122,312. *Falkland Islands*, in the Atlantic, off the S. E. coast of South America; 4,741 sq. m., pop. 686.

IN AUSTRALASIA.—*Australia*, 2,973,127 sq. m., pop. in 1871, 1,561,027, comprising the following colonies: New South Wales, organized in 1788, 323,437 sq. m., pop. 501,611; Western Australia, organized in 1829, 978,000 sq. m., pop. 24,735; South Australia, organized in 1836, 333,323 sq. m., pop. 168,995; Victoria, organized in 1851, 86,831 sq. m., pop. 729,868; Queensland, organized in 1859, 678,000 sq. m., pop. 115,567; Northern territory, not yet organized, 523,531 sq. m., pop. 201. *Tasmania*, formerly Van Diemen's Land, settled in 1803; 26,215 sq. m., pop. 87,868. *New Zealand*, settled in 1839; 106,259 sq. m., pop. 294,023. *Labuan*, an island near Borneo; 50 sq. m., pop. 3,823. *Sarawak*, a protected state in the island of Borneo, established in 1844 by Sir James Brooke; 3,000 sq. m., pop. 50,000.

The following table gives approximately, in round numbers, the area and population of the British empire:

COUNTRIES.	Area, square miles.	Population.
Europe.....	121,000	82,000,000
Asia.....	1,640,000	200,000,000
America.....	3,700,000	5,000,000
Africa.....	250,000	1,700,000
Australasia.....	8,100,000	2,000,000
Total.....	8,811,000	240,700,000

BRITISH GUM, a name given by calico printers to dextrine, produced by heating starch to about 400° F., or until it becomes soluble in cold water and loses its property of forming a blue color with iodine. It is used for stiffening fabrics, and also as an adhesive substance on postage stamps, on labels, on photographic pictures, and the like. (See DEXTRINE.)

BRITISH MUSEUM, a national depository of science, literature, and art, which owes its origin to the will of Sir Hans Sloane, who died in 1753, and bequeathed to the nation his collection of medals and coins, antiquities, seals, cameos, drawings and pictures, and his library, consisting of 50,000 volumes and manuscripts, on the condition of the payment to his heirs of £20,000, being less than half its cost. Parliament accepted this condition, by an act passed in June, 1753, and directed that the Cottonian library, a collection of historical documents made by Sir Robert Cotton during the reigns of Elizabeth and James I., which had been acquired by government in the reign of Queen

British Museum.

Anne, should be added to the Sloane collection, together with a library of about 2,000 printed volumes, called Major Arthur Edward's library, which had existed as an appendage to the Cottonian library since 1738. The book department of the British museum was still further increased by the purchase, for £10,000, of the Harleian library of manuscripts, a collection of about 7,600 volumes of rolls, charters, and other historical documents, which had been accumulated by Robert Harley, earl of Oxford, and his son and successor, Edward Harley. The act of parliament for founding the museum authorized a lottery of £100,000, out of which £10,250 were expended for Montague house with its gardens of 7½ acres, £12,878 were laid out in repairs, and £30,000 were set apart as a fund for the payment of salaries (which at first were moderate), taxes, and other expenses. The collection has since been increased by the munificence of successive parliaments, and by gifts, bequests, and copyrights, until it constitutes a national institution unrivalled in variety and extent by any similar one in the world. It is situated in Great Russell street, Bloomsbury, London. From the rapid increase of the various collections a more commodious

structure became necessary. The present edifice, designed by Sir Robert Smirke, was commenced in 1823, and completed by his younger brother, Sidney Smirke; and in 1845 Montague house was levelled with the ground, and the new portico was finished April 19, 1847. According to the report of the commissioners appointed in 1847-'8, to examine into its constitution and government, the buildings alone had cost since 1823 nearly £700,000. The reading room, completed in 1857, cost £150,000

Reading Room.

more. It is circular, surmounted by a dome 106 ft. high and 140 ft. in diameter, being one foot more than that of St. Peter's, and two feet less than that of the Pantheon; it can accommodate 300 readers, each having a separate desk. The entire public expenditure for the maintenance of the institution, and for the purchase of the various collections, from 1755 to 1858, was more than £1,500,000; in addition to which there have been numerous bequests from private individuals.—The museum consists of seven departments: manuscripts, printed books, antiquities, prints and drawings, mineralogy and geology, zoölogy, and botany; to which should be added the reading room. All of these departments are under separate keepers, to whom and their assistants and subordinates the business of the museum is intrusted. The library occupies the ground floor of the present building, filling 25 spacious departments and galleries, one of which measures 300 ft. in length. In July, 1838, the volumes of printed books, being counted one by one as they stood upon the shelves, were found to be in round numbers 235,000. Counted in the same manner in December, 1849, they were found to amount to 435,000. In May, 1851, they amounted to 460,000, and in July, 1853, to 510,110. In 1860 the number of printed volumes was estimated to be nearly 700,000; and as they increase at the rate of 20,000

a year, the number must now considerably exceed 1,000,000, not counting separate parts and pamphlets. There are 40,000 volumes of manuscripts, exclusive of more than 20,000 original rolls, charters, and deeds. There is also a collection of pamphlets exceeding 200,000 in number, illustrative of English and French history, and a series of newspapers going back to the first appearance of these publications early in the 17th century. The museum contains twice as many books relating to American history as are to be found in any library in the United States. The collection of Hebrew books is the largest in the world. As a whole, the library of the British museum is inferior only to the national library at Paris. The manuscript collections are deposited in four rooms, situated at the southern extremity of the east wing, adjoining Great Russell street. These collections, which have been pronounced to be the most numerous and in some respects the finest in the world, are 11 in number, several of which once belonged to the private libraries of men eminent in rank, and of refined taste and culture. They are as follows: Sloane, acquired in 1753, containing 4,100 volumes; Cottonian, 900 volumes; Harleian, 7,639 volumes; Royal, 1,950 volumes; Lansdowne, in 1807, 1,245 volumes; Hargrave, in 1813, 499 volumes; Burney, in 1817, 524 volumes; King's, in 1823, 438 volumes; Egerton, in 1829, about 2,000 volumes; Arundel, in 1831, 550 volumes; additional, about 5,000 volumes. The progress of the printed collections will be best understood from the following brief chronological summary of the more important donations and purchases, made since the foundation of the library in 1753: 1759, a collection of Hebrew books, 180 volumes, presented by Solomon da Costa; 1762, a unique collection of tracts, published 1640-'80, consisting of about 30,000 articles, presented by George III.; 1766, a collection, rich in biography, bequeathed by the Rev. Dr. Birch; 1768, a collection of Bibles, bequeathed by Arthur Onslow; 1786, a collection of classical authors, 900 volumes, bequeathed by Mr. Tyrwhitt; 1799, a collection of rare editions of the classics and of Italian authors, 4,500 volumes, bequeathed by the Rev. Clayton Mordaunt Cracherode; 1815, Dr. Burney's collection of books on music, purchased; a collection of books belonging to Baron de Moll, 20,000 volumes, purchased at Munich; 1818, Dr. Burney's library of printed books, valued at 9,000 guineas purchased by a special parliamentary grant; 1820, a splendid library, rich in scientific journals and books on natural history, 16,000 volumes, bequeathed by Sir Joseph Banks; 1823, the magnificent library formed by George III., at a cost of £130,000, amounting to about 80,000 volumes, presented by George IV.; 1847, a collection of the Chinese books of Robert Morrison, in 11,500 volumes, presented by the secretary of state for the foreign department; 1847, the library of Thomas Grenville, 20,240 volumes, collected at a cost

of upward of £54,000, bequeathed in 1846, and removed to the museum in 1847; 1848, a collection of Hebrew works formed by H. J. Michael of Hamburg, 4,420 volumes, purchased. Among many rare treasures of the Grenville library may be mentioned the Mentz Latin Bible, commonly called the Mazarin Bible, by Gutenberg and Faust, about 1455, 2 vols., velum; the first printed Psalter, in Latin, by Faust and Schöffer, 1457, being the first book printed with a date; the unique copy, on velum, of the first edition of Livy, by Schweinheim and Pannartz, 1469 (purchased at Mr. Edwards's sale in 1815, for 860 guineas); the first edition of Ovid, by Azzoguidi; a copy of the Aldine Virgil of 1501, the first book printed in Italic type, and the earliest attempt to produce cheap books; a first Shakespeare, one of the finest known, 1623; and a beautiful series of early editions of the *Orlando furioso*.—The collection of antiquities consists of the Egyptian and Assyrian antiquities, the former including the trophies of the Egyptian expedition of 1801; the Elgin marbles, purchased for £35,000; the Phigalian marbles, purchased for £19,000; the Townley marbles, purchased for £28,200; the marbles from Halicarnassus, brought from Budrun in Asia Minor, 1846-'58, and bass reliefs which originally belonged to the mausoleum erected by Artemisia, queen of Caria, in honor of her husband, King Mausolus; there is also a colossal statue supposed to be that of Mausolus himself, broken into 65 pieces, which have been reunited; a portion of the Farnese-marbles, bought in 1864 from the ex-king of Naples for £4,000; Sir William Hamilton's collection of Greek and Etruscan vases, among which is the celebrated Portland vase, which was in 1845 broken in pieces by a lunatic, but has been wonderfully restored; Mr. Richard Payne Knight's collection of coins and medals; and many other works of ancient and modern art. Garrick (whose collection of old English plays is in the library) bequeathed to the museum a statue of Shakespeare which was executed for him by Roubiliac. The world-wide celebrity of the museum is not a little due to the remarkable array of works of art. They have contributed powerfully in facilitating and stimulating the study of the great models of antiquity, especially the Elgin marbles, which are the most perfect specimens of the art of Phidias. The most recent contributions to the department of antiquities are the collections from the ruins of Nineveh and Babylon, by Mr. Layard, Col. Rawlinson, Mr. Loftus, and Mr. Rassam.—The collection of natural history is inferior only to that of the museum in Paris. Among the curiosities is the stuffed skin and skeleton of a gorilla, nearly 6 ft. high, shot in Africa by Du Chaillu, which had before been exhibited in the United States; it is the largest known specimen of the largest species of the quadrumana. There is also a foot of the dodo, a bird now known only by a few scanty fragments, and a single picture said to have been painted from

life.—In the department of mineralogy and geology is a fine collection of meteoric stones, arranged in chronological order; the oldest, weighing 270 lbs., fell at Ensisheim in Alsace in 1492. There is a metallic block from Buenos Ayres, weighing 1,400 lbs., and a meteorite from Melbourne, Australia, weighing 7,000 lbs.—The botanical collection is very large. Its nucleus was the herbarium of Sir Hans Sloane, which consisted of about 8,000 species, bound in 262 volumes; to this in 1820 was added the magnificent herbarium of Sir Joseph Banks. It includes also the Dutch *Hortus Cliffortianus*, with descriptions by Linnaeus, and Burmann's Ceylon plants; and in 1860 was added by purchase the herbarium of Prof. Nuttall, containing 10,000 species, especially valuable from its extraordinary number of typical plants.—The government of the museum is vested in a board of trustees, 48 in number, of whom 1 is named directly by the crown, 23 are official, 9 are named by the representatives or executors of parties who have been donors to the institution, and 15 are elected. The catalogue, which is in manuscript, is drawn up on a uniform plan, and when completed will probably extend to 1,500 or 2,000 volumes. Under the galleries are book presses filled with a large library of reference for the use of readers, comprising most of the standard works on the various branches of learning, and an extensive collection of dictionaries of all languages, biographical works, encyclopædias, parliamentary histories, topographical works, &c. These books can be consulted at pleasure without the usual formalities of the ticket system. Access to the reading room may be obtained by written application to the librarian. Tickets are issued for six months, and at the expiration of this term fresh application is to be made for a renewal. No person can be admitted without a ticket, and the tickets are not transferable. All the buildings of the museum are closed between the 1st and 7th of January, the 1st and 7th of May, and the 1st and 7th of September; also on Sundays, fast days, and holidays. The whole establishment is open to public view on Mondays, Wednesdays, and Fridays, from 9 till 4 during November, December, January, and February; from 10 till 5 during March, April, September, and October; and from 10 till 6 during May, June, July, and August. The reading room is open daily, with the above exceptions, seven hours in the winter, eight hours in the spring and autumn, and nine hours in the summer. Artists are admitted to study in the galleries of sculpture between 9 A. M. and 4 P. M., every week day, except Saturdays. The print room is also closed on Saturdays.

BRITONS. See CELTS.

BRITTANY (Fr. *Bretagne*), an ancient province of France, consisting of the large triangular peninsula which, projecting into the Atlantic, forms the western extremity of that country. Washed on three sides, N., W., and S.,

by the sea, it joined on the E. the provinces of Normandy, Maine, Anjou, and Poitou. Its coast line, indented by numerous bays and harbors, was about 500 m. in length, extending from the bay of Cancale, on the confines of Normandy, to that of Bourgneuf, some 20 m. S. of the mouth of the Loire. Its greatest length from S. E. to N. W. was 185 m.; greatest breadth, 105 m.; area, 13,085 sq. m. It is now divided into the departments of Loire-Inférieure, Ille-et-Vilaine, Morbihan, Côtes-du-Nord, and Finistère. The broken hills by which the interior of the country is intersected, its narrow valleys, its partly unnavigable streams, its vast and thinly populated heaths, its old castles standing on solitary hillocks with their dismantled walls and dilapidated towers, its extensive forests so closely associated with the rites of the ancient druids, its sandy shores

Breton Peasants.

or rugged reefs, the strange garb of its herdsmen and their harsh Celtic language, all combine to stamp the region with a strange and striking character.—Originally independent and known as Armorica, Brittany was indebted for its new name to colonies from Great Britain, which settled at various periods on its territory. These emigrations can be traced as far back as the 3d century; but it is probable that the definitive change of appellation took place only about the middle of the 5th century, when numbers of British families left the island on account of the Anglo-Saxon invasion. Under Charlemagne the paramount power of the Frankish crown over Brittany increased; but its princes, availing themselves of the weakness of his successors, regained their independence, and the principal of them was acknowledged as a king by Charles the Bald. There prevailed among them something of a

feudal organization, the counts of Rennes, Nantes, and Cornouailles being the most powerful, and one of them being generally accredited as the chief of the confederation. About the middle of the 12th century Conan IV. succeeded in bringing all parts of the country under his own control, calling it the county of Brittany. His daughter and heiress Constance married Geoffrey, third son of Henry II. of England, to whom she brought the title and power of count. His son and successor Arthur was assassinated by his uncle, King John of England, when Philip Augustus tried to seize upon Brittany, as he had done with Normandy; but the Bretons resisted, and declared for Alix, a daughter of Constance by her third husband, Guy of Thouars. This Alix married Pierre de Dreux, called Mauclerc, who took the title of duke of Brittany and ruled until their eldest son became of age. This prince, John I., surnamed Rufus, born in 1217, became the head of the ducal family, which reigned until the beginning of the 16th century. On the death of John III., in 1341, his brother John of Montfort and Charles of Blois, who had married the niece of John III., contended for the possession of the duchy. This civil war lasted 24 years. Charles having been killed at Auray in 1364, the ducal crown was secured to the son of John of Montfort, who reigned under the name of John V. Francis II., who reigned from 1458 to 1488, left his daughter Anne heiress of the duchy of Brittany. She was married by proxy to Maximilian of Austria, then king of the Romans; but Anne of Beaujeu, who governed France under the name of her brother, Charles VIII., prevented the alliance from being consummated; she forced the duchess to marry the young king of France, so that Brittany was for the first time united to the kingdom (1491). On the death of Charles VIII., Louis XII. hastened to divorce his first wife, and to marry his predecessor's widow, thus securing the union between France and Brittany. But it was not till 1532, during the reign of Francis I., that Brittany was declared to be an integral part of the French kingdom. Although losing its independence, it persevered in maintaining the rights and privileges which had been secured to it by the treaty of union. The royal power was limited here by a representative government called the estates of Brittany. The assembly, the sessions of which were held every other year, consisted of the three orders, the clergy, the nobility, and the *tiers état*. The king was not allowed to lay any tax, this being regulated by the assembly, which voted for the support of the royal government what was called a gratuitous gift. The province had also its own courts of justice, the highest of which was known as the parliament of Rennes, with four seneschal jurisdictions. More than once Brittany was compelled to stand in defence of its immunities; but its people, while vindicating what they thought their rights, showed

great devotion to their French sovereign; and when the revolution occurred, the Chouans of the province fought the last battle in behalf of royalty. Brittany has never been distinguished for commerce or manufactures, but its seamen are among the boldest in the world; those of St. Malo, Brest, and Lorient are to be met in the most distant waters, more generally engaged in fishing than in trade. The province was usually divided into Western or Lower Brittany and Eastern or Upper Brittany.

BRITTON, John, an English antiquary, born at Kingston St. Michael, Wiltshire, July 7, 1771, died in London, Jan. 1, 1857. He was apprenticed to a London wine merchant, with whom he remained six years. For seven years afterward he struggled with poverty, eking out a bare existence by various employments. A book on the adventures of Pizarro, which he wrote, introduced him to the publisher of the "Sporting Magazine," who employed him with another person to compile the "Beauties of Wiltshire," which appeared in 1801, and succeeded so well that the authors were employed to compile the "Beauties" of all the other counties of England, in 26 volumes. In 1805 he published the first part of the "Architectural Antiquities of England;" it was completed in 1815 in 5 vols. 4to, richly illustrated. His distinct productions, 87 in number, are valuable, not only for the information they supply, but for their numerous and beautiful engravings. He published in 1847 an "Essay on the Authorship of the Letters of Junius," in which he endeavored to prove that Junius was Col. Barré, aided by Lord Shelburne and Dunning. Then, at the age of 76, having accumulated a handsome fortune, he discontinued his labors as author. His friends, constituting the "Britton Club," entertained him at a public dinner, and subscribed over £1,000 for a testimonial to be presented to him. On his own suggestion, the money was devoted to bringing out his autobiography.

BRIVES, or Brives-la-Gallarde, a town of Limousin, France, in the department of Corrèze, situated in the valley of the Corrèze, 13 m. S. W. of Tulle; pop. in 1866, 10,889. Its fine appearance at a distance is not realized in its interior. The most remarkable buildings are a communal college, a hospital, a library with 21,000 volumes, and an ancient Gothic house, dating, it is said, from the time of the English occupation. The manufactures embrace woollens, muslins, silk, handkerchiefs, and cotton yarns. There are extensive bleacheries and distilleries, and a brisk trade is carried on in brandy, wine, chestnuts, cattle, and truffles, the Brives chicken truffle pie enjoying much reputation. Cardinal Dubois and Gen. Brune were born here.

BRIXEN, a town of Tyrol, capital of a circle of the same name, 89 m. S. by E. of Innsbruck, at the confluence of the rivers Eisack and Rienz, on the railroad leading through the Brenner pass; pop. about 4,000. Its position is strategically very important, owing to the high and

steep mountains on each side. The town is spoken of as early as the 9th century. It has a Catholic gymnasium, and has been the residence of a bishop since 992. The Catholic council of 1080, which pronounced the removal of Pope Gregory VII., was held here. In the peasants' war in 1525 Brixen was occupied and sacked. In the vicinity of the town is Fort Francis, or Franzensveste, erected in 1845, commanding the valley of the Eisack, and the three roads from Bavaria, Italy, and Carinthia, which join at Brixen.

BRIXHAM, a seaport and market town of Devonshire, England, on the coast of the English channel, 23 m. S. of Exeter; pop. in 1871, 4,390. It is noted for its fisheries, which employ more than 200 vessels and 1,500 seamen. It was the landing place of William III. when he came to take possession of the English throne. A part of the stone upon which he set foot has been built into a monument, with the inscription: "On this stone, and near this spot, William prince of Orange first set foot, on his landing in England, 5th of November, 1688."

BROACH, or Baroach. I. A district and collectorate of Bombay, British India, extending in a narrow strip along the W. coast of the main peninsula and the E. shore of the gulf of Cambay; area, about 1,350 sq. m.; pop. estimated at 200,000. It contains, besides the capital, about 400 villages, the inhabitants of which are mostly engaged in agriculture, especially in the cultivation of cotton, large quantities of which are exported. The district was annexed to the territory of the East India company in 1781, but in 1782 the Mahrattas, who had formerly held it, were allowed to again assume the government. In 1803, with a considerable extent of other territory, it was finally ceded to the company. **II.** A city, capital of the district, in lat. 21° 46' N., lon. 73° 14' E., on the Nerbudda river, about 25 m. from its mouth, and 29 m. S. by W. of Baroda; pop. about 31,500. It has a few fine buildings, but in general the houses are low and unattractive in appearance. Much of the city is now in ruins, and the river filled with sand so that large vessels cannot approach the place. Broach is supposed to be the Barygaza of Ptolemy and Arrian.

BROAD RIVER, a stream of North and South Carolina, rising at the foot of the Blue Ridge, in the western part of the former state, and entering South Carolina on the line between Spartanburg and York counties. It then takes a southerly course through a rich and highly productive tract of country, covered with fields of maize and cotton, and finally unites with the Saluda to form the Congaree river. The city of Columbia is at their junction.

BROADUS, John Albert, D. D., an American clergyman, born in Culpeper co., Va., Jan. 24, 1827. He was educated at the university of Virginia, and from 1851 to 1853 was assistant professor of ancient languages there. He then

became pastor of the Baptist church in Charlottesville, and in 1859 professor of New Testament interpretation and homiletics in the Southern Baptist theological seminary at Greenville, S. C., where he still is (1873). As a Greek scholar and New Testament critic Dr. Broadus stands at the head of the Baptists of the south; but his only publication in this department as yet is an elaborate review (in the "Religious Herald," 1866 and 1868) of the American Bible Union's revised version of the New Testament. In 1870 he published a work on "The Preparation and Delivery of Sermons," which has been adopted as a text book in several theological seminaries. His other publications consist of sermons and review articles, and a series of papers ("Recollections of Travel") in the "Religious Herald," 1872-'3, describing a tour in Europe, Egypt, and Palestine.

BROCADE (Span. *brocado*, embroidered), a fabric resembling embroidered stuff, formerly much in vogue for rich dresses. It was originally made entirely of threads of gold or of silver, or of the two mixed. Ornaments of flowers and foliage were interwoven and raised above the surface of the cloth. When a cheaper material, as silk, was substituted for the metallic threads, the raised ornaments of leaves and flowers still continued to characterize the brocades. Brocades are now comparatively little in use.

BROCCHI, Giovanni Battista, an Italian mineralogist and geologist, born at Bassano, Feb. 18, 1772, died at Khartoom, Nubia, Sept. 25, 1826. In 1808 he was appointed inspector of mines, and in 1814 he published a work on the structure of the Apennine range, with an account of the fossils of its strata. He corrected the erroneous view of Brieslak, who supposed Rome to occupy the site of an extinct volcano, to which he ascribed the tufa and other volcanic materials found on the seven hills. In 1823 Brocchi received a commission from Mehemet Ali to examine Sennaar, but died from the effects of the climate.

BROCCOLI, a species of cabbage, belonging to the genus *brassica*, differing from the other species by its smaller seeds and the tendency of its flowers to press together into fleshy heads. It most nearly resembles the cauliflower, from which it differs by no very precise characteristics. The broccoli is best raised by sowing the seed in open beds and transplanting the plants once or twice. It may be produced either in spring, summer, or autumn, according to the time when the seed is sown. It has a woody stem, and may be propagated not on-

ly by seed, but by cuttings of its stem. To effect the latter method, let a portion of the old stem containing an eye or a bud, after being well dried in the sun, be dibbled into the soil, and not be watered till it shows signs of growing.

BROCK, Isaac, a British general, died Oct. 13, 1812. He captured Gen. Hull and his whole force at Detroit, Aug. 16, 1812, and fell in the battle of Queenstown, Canada, on the Niagara river. During his funeral the guns of the American forts were fired as a token of respect. A monumental column was erected on the spot where he fell; this was partially destroyed during the disturbances of 1840, and has been replaced by another, 194 ft. in height, which is ascended by a spiral staircase inside.

BROCKEDON, William, an English artist and inventor, born in Devonshire, Oct. 13, 1787, died in London, Aug. 29, 1854. He was the discoverer of a method by which plumbago and its dust (previously thrown away as valueless) were freed from impurities and resolidified, so as to make a superior description of lead pencils. He was the author of the "Passes of the Alps," with over 100 folio engravings from drawings by himself. He also produced "Italy, Classical and Picturesque" (folio, 1842-'3), and "Egypt and Nubia" (3 vols. folio, 1846-'9).

BROCKHAUS. I. Friedrich Arnold, founder of the publishing firm of Brockhaus in Leipsic, Germany, born at Dortmund, May 4, 1772, died in Leipsic, Aug. 20, 1823. He was educated at the gymnasium of his native town, and afterward sent into a merchant's counting-room at Düsseldorf. In 1793 he went to Leipsic, where he devoted himself for two years to the acquisition of scientific knowledge and the principal modern languages of Europe. In 1795 he established at Dortmund a mercantile house for the sale of English manufactures, which he removed to Arnhem in the Netherlands in 1801, and to Amsterdam in 1802. Although he managed his business with success in a pecuniary sense, he abandoned it out of distaste for mercantile pursuits in 1804, and entered into the book trade at Amsterdam. A periodical in Dutch (*De Ster*, "The Star"), started by Brockhaus in 1806, and devoted to politics and literature, was suppressed by the government on account of its opinions on political and ecclesiastical matters. The *Amsterdamsch Avond-Journal* ("Amsterdam Evening Journal"), which succeeded the *Ster*, did not continue long. The confusion into which Europe was thrown by the Napoleonic wars was unfavorable to literary enterprises, and after the annexation of Holland to the French empire (1810) Brockhaus returned to Germany, and opened an establishment in Altenburg (1811). In 1808 Brockhaus purchased the copyright of the German *Conversations-Lexikon*, which had been commenced in 1796. In 1809-'10 he completed the first edition by the publication of two supplementary volumes. In 1812 he be-

Broccoli.

gan to publish the second edition of this work, which was finished under his own editorship. Shortly before the battle of Leipsic he commenced a political newspaper called *Deutsche Blätter*, which breathed a patriotic German spirit. This journal lasted from Oct. 14, 1813, to May, 1816. The peace of 1815 enabled him to enter upon large literary undertakings. In 1817 the business had increased to such an extent that Brockhaus removed to Leipsic, and added a printing office to his former establishment. His *Conversations-Lexikon* ran through six editions in his lifetime, and numerous other publications of the first rank raised the firm to a high position in German literature. Among the more important publications of the firm during the lifetime of its founder may be mentioned Ebert's *Allgemeines bibliographisches Lexikon* (1821) and Von Raumer's *Geschichte der Hohenstaufen* (1823), besides several periodicals edited by himself; among these is the *Literarisches Wochenblatt*, now published as the *Blätter für literarische Unterhaltung*. His liberalism brought him under the ban of the reactionary Prussian government, which in 1821 ordered a censorship upon all the publications of Brockhaus, which lasted until his death. His biography was published by one of his relatives in 1872 (2 vols.).—The firm of F. A. Brockhaus was continued by the two sons of the founder, FRIEDRICH and HEINRICH. Under their auspices the *Conversations-Lexikon* has passed through five new editions (11th ed., 15 vols., 1864-'8, with a supplement in 2 vols., 1872-'3), to which several companion works were added from time to time, namely: the *Conversations-Lexikon der neuesten Zeit und Literatur* (1832-'4), the *Conversations-Lexikon der Gegenwart* (1838-'41), and the *Gegenwart* (1848-'56). In January, 1857, the firm commenced a supplementary work of this character, called *Unsere Zeit, Jahrbuch zum Conversations-Lexikon*, published in monthly and ultimately in semi-monthly parts, which is still continued. The *Systematischer Bilder-Atlas zum Conversations-Lexikon* was published between 1844 and 1851. In 1854-'6 an abridgment of the 10th edition of the *Conversations-Lexikon* appeared in 4 volumes (*Kleineres Brockhaus'sches Conversations-Lexikon*; 2d ed., 1861-'4). The "Encyclopædia Americana," edited by Dr. Francis Lieber (Philadelphia, 1829-'33), was based upon the 7th edition of the *Conversations-Lexikon*. Among the most notable periodical publications of this firm are the continuation since 1832 of the *Allgemeine Encyclopædie der Wissenschaften und Künste*, by Ersch and Gruber; the *Pfennig-Magazin*; the *Leipziger Allgemeine Zeitung*, commenced in 1837; and the *Deutsche Allgemeine Zeitung*, since 1843. In 1850 Friedrich Brockhaus retired from business, and Heinrich for a time constituted alone the firm of F. A. Brockhaus; in 1854 and 1863 his two sons, HEINRICH EDUARD and HEINRICH RUDOLF, upon reaching respectively their 25th year, were admitted as

members of the firm. The firm of F. A. Brockhaus has printing, lithographing, binding, and type-founding establishments connected with its book-publishing and general bookselling business. II. Hermann, a German orientalist, third son of Friedrich Arnold, born in Amsterdam, Jan. 28, 1806. He studied the oriental languages at Leipsic, Göttingen, and Bonn. The languages and literature of Hindostan especially engaged his attention; for the better acquisition of this branch of knowledge he resided for a long time in Paris, London, and Oxford. In 1839 he was appointed professor extraordinary at the university of Jena, and in 1841 at Leipsic. In 1848 he was called to the chair of Sanskrit language and literature in the latter university. He has edited and published several Sanskrit and Persian works, some of them in Roman type. He was one of the founders of the German oriental society, the *Zeitschrift* issued by which he has edited since 1852. In 1856 he undertook the editing of Ersch and Gruber's *Allgemeine Encyclopædie*.

BROCKLESBY, Richard, an English physician, born of a Quaker family at Minehead, in Somersetshire, Aug. 11, 1722, died in London, Dec. 11, 1797. He studied medicine at Edinburgh, and subsequently at Leyden, where he took his doctor's degree in 1745. In 1746 he published an essay on the mortality of horned cattle. He was physician of the British forces in Germany from 1758 to 1763, and published his observations on medical hospitals on his return. In 1763, when John Wilkes was severely wounded in a duel with Mr. Martin, he was attended by Dr. Brocklesby. In 1765 he was elected fellow of the royal society, which at his suggestion founded a professorship of chemistry at the royal military academy of Woolwich. For over 40 years he was on intimate terms with the leading statesmen, authors, artists, and other persons of note in London. He attended on Dr. Johnson for many years without fee. When it was proposed that Johnson should visit the continent for a milder climate, and want of means was mentioned as a reason why the journey was to be abandoned, Brocklesby offered to settle on him £100 for life.

BROCKPORT, a village in the town of Sweden, Monroe county, N. Y., on the Erie canal and a branch of the New York Central railroad, 18 m. W. of Rochester; pop. in 1870, 2,817. It is noted for the manufacture of pumps, and contains also three manufactories of reapers and mowers, several mills, seven or eight churches, a state normal school, a national bank with \$50,000 capital, and two weekly newspapers.

BROCKVILLE, a town of Ontario, Canada, in Leeds county, on the St. Lawrence, at the foot of the Thousand Islands, 125 m. S. W. of Montreal, and 10 m. S. W. of Prescott; pop. in 1871, 10,475. It occupies a pleasant situation, and is substantially built. There are manufactures of hardware, stoves, white lead, gloves, agricultural implements, and chemicals, including

superphosphates of lime, a custom house, and telegraph offices. The Grand Trunk railway passes north of the town, and the Brockville and Ottawa railway connects it with Ottawa, 65 m. N. A ferry boat crosses the river to Morristown, N. Y., in summer; and passenger steamers and propellers call here daily.

BRODERICK, David Colbreth, an American politician, born in Washington, D. C., in December, 1818, killed in San Francisco, Sept. 21, 1859. In early life he worked as a stone mason in New York, and was connected with the fire department, of which he became engineer. In 1846 he was an unsuccessful candidate for congress. He removed to California in 1849, and in 1850 was elected to the state senate, and in 1856 to the United States senate, where he opposed the attempt to force slavery into Kansas by means of the Lecompton constitution. On account of some expressions used in debate he was challenged by David S. Terry, a judge of the California courts, and was killed in the duel which ensued.

BRODERIP, William John, an English naturalist, born at Bristol in 1787, died in 1859. He took his degree at Oriel college, Oxford, was called to the bar in 1817, edited a legal work on sewers, and published three volumes of law reports. He was appointed by Sir Robert Peel a police magistrate for a metropolitan district, which office he retained for 34 years. He contributed largely to the "Penny Cyclopædia," and the greater part of the zoological department of the "English Cyclopædia" is his work. He is the author of many essays in the "Quarterly Review" on subjects of natural history. He also wrote "Zoological Recreations" (London, 1847), and "Leaves from the Note Book of a Naturalist" (1852).

BRODHEAD, John Romeyn, an American historian, born in Philadelphia, Jan. 2, 1814, died in New York, May 6, 1873. He graduated at Rutgers college in 1831, studied law, practised for two years in New York, and afterward devoted himself to the study of American history. In 1839 he went to Holland and was attached to the United States legation at the Hague. The legislature of New York having passed an act to appoint an agent to procure and transcribe original documents referring to the history of the state, he was commissioned in 1841. The three following years were spent by him in searching the archives of Holland, England, and France for papers which might serve to illustrate the history of New York, and complete the records of the state at Albany. As the result of his labors he obtained a collection of more than 5,000 separate papers, many of them previously unknown to historians. He deposited his collection in the secretary of state's office, and made his final report as agent, in February, 1845. All these documents were ordered to be published by an act of the legislature of March 30, 1849. On the appointment of Mr. Bancroft as minister to England in 1846, Mr. Brodhead was made secretary of

legation, and remained in London till 1849. He now set to work upon his "History of the State of New York," the first volume of which, containing the period under the government of the Dutch, was published in 1853, and the second in 1871. In 1853 he was appointed naval officer of the port of New York, which post he held till 1857.

BRODIE, Sir Benjamin Collins, an English surgeon, born at Winterslow, Wiltshire, June 9, 1783, died at Betchworth, Surrey, Oct. 21, 1862. He was educated at a free school in London, and under Sir Everard Home at St. George's hospital, where he became assistant surgeon in 1808, and afterward surgeon. In 1811 he received the Copley medal of the royal society for his physiological papers in the "Philosophical Transactions." From 1819 to 1823 he was professor of anatomy at the royal college of surgeons. In 1834 he was created a baronet; and in 1837 he became sergeant surgeon to the queen. He was a member of several learned societies at home and abroad. He suggested important improvements in many kinds of surgical instruments, and in numerous cases substituted simple and less violent methods of surgical operation. He published numerous articles in the medical journals, and a series of physiological papers on the action of the nervous centres in the production of animal heat, in the "Philosophical Transactions" from 1810 to 1812. His published works, some of which have passed through several editions, are: "Pathological and Surgical Observations on Diseases of the Joints" (1818; 5th ed., 1850); "Lectures on Diseases of the Urinary Organs" (1832; 4th ed., 1849); "Physiological Researches" (1851); and "Psychological Inquiries" (1854; 8d ed., 1856).—His son, the present Sir BENJAMIN COLLINS BRODIE, born in 1817, was appointed professor of chemistry at Oxford in 1855, and was president of the chemical society in 1859 and 1860. He has contributed to the "Philosophical Transactions" and the "Journal of the Chemical Society."

BRODY, a town of East Galicia, Austria, capital of a district of the same name, 52 m. E. N. E. of Lemberg; pop. in 1869, 18,890, of whom two thirds are Jews, whence it has been called "the German Jerusalem." It is an important commercial focus for Galicia, Roumania, Turkey, Germany, and chiefly for Russia, on the frontier of which it is situated. In 1779 it was established by Austria as a free port. It is generally dirty and badly built, but has a number of fine buildings, among which are the Potocki palace, the principal synagogue, and several churches. It is the seat of an imperial administrative board for the district, and of a commercial tribunal, has a superior school for the Jews, and a gymnasium. Two great annual fairs are held, and the transactions amount to about \$20,000,000 yearly. The traffic is in grain, horses, cattle, tallow, hides, furs, leather, wax, honey, dried fruits, colonial products, ironmongery, jewelry, wines, porcelain, &c.

It also has extensive tanneries and linen factories. From May 8 to Oct. 7, 1849, Brody was occupied by Russian troops. In 1859 the town was desolated by a great fire.

BRODZINSKI, Kazimierz, a Polish soldier and poet, born at Królówko in 1791, died in Dresden, Oct. 10, 1835. In 1809 he entered the military service of his country, and fought against the Austrians; in 1812 he participated in Napoleon's Russian campaign, and in 1813 in the campaign in Germany, until he was taken prisoner at the battle of Leipsic. When the university of Warsaw was established, he became professor of æsthetics and literature. He was the first who attempted to reinvigorate Polish poetry from the national sources, instead of imitating Latin and French models. He also translated many of Scott's novels into Polish, in 10 vols. His complete works were published in 1842-'4.

BROFFERIO, Angelo, an Italian poet and politician, born at Castelnuovo, Piedmont, in 1802, died at Verbanella, on Lago Maggiore, May 26, 1866. He practised law in Turin, chiefly in criminal cases, and was at the same time an influential journalist. Having early agitated in favor of the national cause, he became the democratic leader in the chamber of deputies, where he represented Cavaglia, 1848-'53, Genoa, 1853-'60, and subsequently a small borough of southern Italy, after having lost ground by his opposition to Cavour, whom he had satirized in his *Tartufo politico*. Several of his many dramas were successful. A 5th edition of his *Canzoni* (patriotic songs in the Piedmontese dialect) appeared in 1858; and shortly before his death he composed *L'inno de guerra*, a popular war hymn. He also published a history of Piedmont from 1814 to 1851 (5 vols., 1849-'52), and *I miei tempi* (20 vols., 1858-'61).

BROGLIE, or *Brogli*, the name of a family originally from Piedmont, established in France toward the middle of the 17th century. **I. François Marie**, born at Ohieri, in Piedmont, in 1611. He entered the French service, in which he distinguished himself, was made governor of the Bastille, and died July 2, 1656. **II. Victor Maurice**, count de, born about 1645, distinguished himself in the army, became marshal of France, and died August 4, 1727. **III. François Marie**, the first duke de, born Jan. 11, 1671, died May 22, 1745. He was a lieutenant general and marshal. In 1725 he was appointed minister to England, and negotiated the treaty between France, England, and Prussia. He afterward became distasteful to the ministers, and was banished to his estate at Broglie, where he died. **IV. Victor François**, second duke de, born Oct. 19, 1718, died at Münster in 1804. He was a lieutenant general during the seven years' war, routed the Prussians at the battle of Berghen, was created a prince of the German empire by Francis I., became marshal of France in 1759, and minister of war in 1789. In 1792 he led a body of French *émigrés* in the invasion

of Champagne. **V. Claude Victor**, prince de, son of the preceding, born in Paris in 1757, guillotined June 27, 1794. He was elected deputy to the states general, gave evidence of liberal opinions, and was for a while president of the constituent assembly. Subsequently he was brigadier general in the army on the Rhine. After the 10th of August, 1792, refusing to obey the decree of the legislative assembly suspending the power of the king, he was removed, and ultimately arraigned before the revolutionary tribunal, and executed. **VI. Achille Léonce Victor Charles**, duke de, son of the preceding, born in Paris, Nov. 28, 1785, died there, Jan. 25, 1870. He gained the regard of Talleyrand, who in 1814 presented his name for appointment to the chamber of peers. During the hundred days he was elected an officer in the national guards. He married at Leghorn, Feb. 15, 1816, the daughter of Mme. de Staël. After the second restoration he resumed the title of duke, instead of that of prince, previously used in the elder branch of his family. At the trial of Marshal Ney he used every effort to save his life. In 1822 he denounced the slave trade; and after the revolution of 1830 he succeeded as minister in concluding a convention on the right of search, by which he hoped to suppress that traffic. He was appointed minister of public instruction and president of the council of state, in August, 1830, but soon disagreed with his colleagues and resigned. On Oct. 11, 1832, he reentered the cabinet as minister of foreign affairs, under Marshal Soult, with Guizot and Thiers as his colleagues. Having been defeated on a question of indemnity to the United States, he retired, April 4, 1834. In 1849 he was elected to the legislative assembly by the department of Eure, and figured among the leaders of the conservative party. In 1850 he visited Louis Philippe in England. He protested against the *coup d'état* of Dec. 2, 1851, was for a short time under arrest, and afterward went to London. On his return to France in 1852, he refused to take the oath on the constitution, and tendered his resignation as a member of the council of the department of Eure. In 1856 he was made a member of the French academy, and in 1866 member of the academy of moral sciences. Three volumes of his *Écrits et Discours* were published in Paris in 1863. **VII. Albertine Ida Gustavine de Staël**, duchess de, wife of the preceding, born in 1797, died in September, 1838. She was the only daughter of Mme. de Staël, and was educated under her influence. After her marriage in 1816 with the duke de Broglie, her house in Paris became a resort of the most distinguished society. She was noted for her zeal as a Protestant, though her husband was a devout Roman Catholic. After the death of her brother, Auguste de Staël, in 1827, she prepared a complete edition of his *Ouvrages diverses* (5 vols., Paris, 1829), with a notice containing interesting particulars of her mother's life. Her essays were collected after her death

(*Fragments sur divers sujets de religion et de morale*, Paris, 1840); the most remarkable of these relate to the part assigned to women in philanthropical labors and in the improvement of public morals. **VIII. Albert**, duke de, son of the preceding, a French statesman and author, born June 13, 1821. He early acquired literary reputation by his contributions to the *Revue des Deux Mondes*, and was elected in 1862 a member of the academy, in place of Lacordaire. His principal work, *L'Église et l'Empire romain au IV^e siècle* (2 vols., 1856), passed through many editions. He published a French version of Leibnitz's *Système religieux*, and wrote *Questions de religion et d'histoire* (2 vols., 1860), and various disquisitions, the principal feature of which was his attempt to reconcile the authority of the pope with modern views of progress. Under M. Thiers's presidency he has been for a short time minister of foreign affairs and ambassador at London (1871-'72). **IX. Maurice Jean Madeleine**, bishop of Ghent, born Sept. 5, 1766, died in Paris, July 20, 1821. In 1805 he was almoner to Napoleon, became bishop of Ghent in 1807, was imprisoned at Vincennes in 1811, and restored to the see of Ghent in 1814. Refusing to take the oath of allegiance to the king and constitution of the Netherlands, he was in 1817 exiled from that kingdom, and returned to France.

BROGNI, Jean Allarmet, cardinal de, a Roman prelate, born at Brogni, Savoy, in 1342, died in Rome, Feb. 16, 1426. He was a swineherd in his youth, and was successively made bishop of Viviers and of Ostia, archbishop of Arles, and bishop of Geneva, and finally cardinal and chancellor of the church of Rome. During the great schism which divided the church for more than 40 years, Brogni devoted himself to the work of conciliation. The council of Constance being called for that purpose by John XXIII. and the emperor Sigismund, the former was deposed at the sixth session, after which Brogni presided as senior cardinal until the 41st, when Cardinal Colonna was elected pope, Nov. 14, 1417, chiefly through Brogni's influence, under the name of Martin V., and the holy see was once more established at Rome. As president of the council he had to pronounce the sentence of death upon Huss, to whom he had shown great kindness during the trial. The cardinal was the founder of the hospital of Ancey, of the college of St. Nicholas at Avignon, and other charitable institutions.

BROGUE, or **Brogan**, originally a sort of clog or shoe made of untanned skin, and worn by the Irish and Scotch. This article of dress fell into disuse early in the 15th century, and the substitute was made of tanned leather, with thick soles, freely studded with large-headed nails, which took the name of the article they supplanted. These brogues or brogans continue to be worn in Ireland. By a natural process the peculiar manner in which the wearers of the brogue pronounced the English language became universally known as the brogue, and

the application of this term is limited almost exclusively to the Irish.

BROHAN. I. Augustine Suzanne, a French actress, born in Paris, Jan. 29, 1807. She was educated at the Paris conservatory, where in 1821 she obtained the first prize for proficiency in comedy. She made her first appearance on the Parisian stage at the Théâtre Français in 1824, and during the next 18 years acted at that theatre, the Odéon, and the Vaudeville, identifying herself chiefly with the last named. In 1842, when at the height of her reputation, she retired from the stage. Her personations were noted for acuteness, vigor, and an unusual command of the conventional stage resources. **II. Joséphine Félicité Augustine**, a French actress, daughter of the preceding, born in Paris, Dec. 2, 1824. She was educated at the conservatory, and like her mother gained at 14 years of age the first prize for comedy. Being of a devotional turn of mind, she almost immediately afterward entered a convent, and was with great difficulty persuaded to make her début on the stage. She first appeared at the Théâtre Français in 1839, as Dorine in Molière's *Tartuffe*, and created a favorable impression by her grace, vivacity, and modesty. She was at once engaged at this theatre, and soon became a skilful interpreter of Molière, excelling in such parts as Dorine, Toinette in the *Malade imaginaire*, Cléanthis in *Amphitryon*, and Suzanne in Beaumarchais's *Mariage de Figaro*. She has also acted in many modern pieces, including Hugo's *Le roi s'amuse* and Dumas's *Mlle. de Belle-Isle*. A few slight pieces of her own have been successful on the stage, and she has figured occasionally as a journalist; but her attacks in the *Figaro* on her old friend Victor Hugo aroused so much feeling against her that she relinquished journalism. After the death of Rachel she succeeded to her chair at the conservatory. **III. Émilie Madeleine**, a French actress, sister of the preceding, born in Paris, Oct. 21, 1833. She was educated at the conservatory, where she gained the prize for comedy, and at 17 made her début at the Théâtre Français. She soon became a favorite, being not less noted for her personal charms than for her vivacity and intelligence as an actress, particularly in the modern drama. In 1854 she was married to Mario Uchard, a dramatic author.

BROKE, Sir Philip Bowes Vere, a British admiral, born Sept. 9, 1776, died in Suffolk in 1841. He was educated at the royal academy in Portsmouth, entered the navy in 1792, served in the wars between France and England, and was in command of the Shannon, protecting the whale fishery in the Greenland seas, when in 1812 war was declared between the United States and Great Britain. Despatched with a squadron to blockade the American ports, he appeared with the Shannon off the harbor of Boston, immediately after Capt. Lawrence had been promoted to the command of the Chesapeake. He sent a letter to Lawrence, challenging him to an engagement. The

latter, however, deeming his appearance a challenge, had ordered the Chesapeake to lift her anchors before the letter reached its destination. The Chesapeake was badly manned, equipped, and officered, the crew being to a large extent foreign mercenaries murmuring about their prize money, the ship being one of the worst in the navy, the first lieutenant being sick on shore, and the posts of two others being filled by midshipmen. The action began June 1, 1813, at 5 h. 45 m. P. M., in sight of the shore lined with spectators; and within 15 minutes Lawrence was mortally wounded and his ship in the possession of the enemy. For this victory Capt. Broke was made a baronet and knight commander of the bath.

BROKEN WIND, a disease of the lungs of the horse, incapacitating him from all violent and rapid exertion. It is immediately recognizable by the manner of breathing. The inspiration is performed in somewhat less than the natural time, but with an increased degree of labor; the expiration is accomplished by a double effort, in the first of which the usual set of muscles operate, and in the other the auxiliary muscles, particularly the abdominal, are put on the stretch, to complete the expulsion more perfectly; and that being done, the flank falls, or the abdominal muscles relax with a kind of jerk or spasm. Broken wind is preceded or accompanied by a characteristic cough, seemingly cut short, grunting, and followed by wheezing. The disease is believed to be hereditary, and in some degree consequent on malformation, on a narrow chest, a fragile membrane, and a predisposition to inflammatory diseases. Horses which are greedy feeders, and distend the stomach with large quantities of innutritious food, of which they do not readily get rid, are peculiarly liable to broken wind; which may also be produced by giving a horse a severe gallop on a full stomach, even where there may have been no previous chronic affections. When a horse is once thoroughly broken-winded, there is no cure, the structure of the lungs being permanently injured. The food should be the most nutritious, and that which will lie in the smallest compass—good oats, little hay, no chaff. Green food is particularly beneficial, and carrots appear to have a direct effect on the respiratory organs.

BROMBERG (Pol. *Bydgoszcz*), a city of Prussia, capital of an administrative district of the same name in the province of Posen, on the river Brahe, 6 m. from its confluence with the Vistula, and 69 m. N. E. of Posen; pop. in 1871, 27,734. It has a gymnasium and normal schools, several manufactories of linen and woollen stuffs, leather, sugar, chicory, Prussian blue, &c. There are a Protestant and two Roman Catholic churches, two convents, and a synagogue. It is connected by railroad with Berlin, Posen, and other cities. The Bromberg canal unites the rivers Brahe and Netze, and opens water communication between the Vistula and the Oder and Elbe.

BROME, a S. W. county of Quebec, Canada, bounded S. by Vermont and E. by Lake Memphremagog; area about 350 sq. m.; pop. in 1871, 13,757. It is traversed from north to south by spurs of the Green mountains. Lake Brome, one of the sources of the Yamaska river, is situated near its northern border. Capital, Knowlton.

BROME, Richard, an English dramatist, died in 1652. He was originally a servant to Ben Jonson. The "Northern Lass," the first of 15 comedies which he wrote, obtained Jonson's commendation. Brome joined with Thomas Heywood in writing the "Lancashire Witches" and two other plays. Soon after his death his plays were collected and published by ALEXANDER BROME (born 1620, died 1666), who, though a namesake, was no relation, and wrote satirical songs and epigrams on the loyalist side during the protectorate, as well as a comedy and a translation of Horace.

BROMIDES, salts of bromine with various radicals, of which the most important are those found with potassium, sodium, ammonium, lithium, iron, and mercury. The alkaline bromides crystallize in cubes or rectangular prisms, and are very soluble in water. These are considerably used in medicine. Bromide of potassium in large doses (20 to 60 grains) produces sleep, as has been supposed, by giving rise to anæmia of the brain. The reflex excitability of the nervous centres in general, and the spinal cord in particular, is much diminished, and in frogs may be destroyed before the power of voluntary motion is lost. They are used to relieve sleeplessness and nervous excitability, and in various diseases characterized by increased reflex activity, of which epilepsy is the most important. This disease is often controlled, and seems sometimes to be cured, by the continued use of bromides. They have also a sedative effect on the genital organs. The bromides have been used as alteratives.

BROMINE (Gr. *βρωμος*, a stench), a chemical element discovered by Balard in 1826 in the bitter or mother liquor of the salt works of Montpellier, France, and so named in consequence of its disagreeable odor. The fact that chlorine water, when added to the lye from fucus ashes, after the addition of starch paste, gave besides the usual blue color an orange-yellow zone at the top of the liquid, was the immediate occasion of Balard's discovery. Since the announcement of the discovery, many chemists have occupied themselves with investigating the occurrence, properties, and uses of bromine, and it has now attained a position of the first importance in medicine and the arts. Bromine has been found in the mineral kingdom in combination with silver and zinc, and in the salt deposits of Stassfurt; it has also been detected in urine, coal beds, Chili saltpetre, and fucus ashes. According to Von Bibra, the amount of bromine in the Atlantic ocean is 24 grains per gallon; in the Dead sea, examined by Herapath, 121.5 grains; in the dried residue

of the Mediterranean, 1.15 per cent. In the mineral springs of Kreuznach Ure found 10.8 grains; in Kissingen water, determined by Kastner, there is 0.44 grain; in Tenbury, Worcestershire, examined by Ure, as much as 12.5 grains; and at Arnstadt, according to Hartung, 13.6 grains. In the United States, bromine has been detected in various saline springs, for the first time in the brines of Onondaga in 1830, by Hayes and Silliman. The quantity in one of the artesian wells of Saratoga, determined by Dr. Chandler, is 3.63 grains; in the brine of Saginaw valley Dr. Chilton found 7.65 grains; at Tarentum, Penn., 6 grains; in the Salina brine, analyzed by Dr. Goessmann, 1.36 grain per gallon is reported. Many mineral waters in all parts of the world have been shown to contain bromine, and for a long time the chief commercial supply was from these sources. Since the opening of the Stassfurt salt mines the chief product is derived from this source. As much as 300 grains per gallon has been obtained from the mother liquors of Stassfurt. Only two or three of the manufactories at this place have economized this substance, as the unprecedented supply has reduced the price below profitable manufacture; the decrease in price has also been hastened by the large production in the United States. At Tarentum, Sligo, and Natrona in western Pennsylvania, at Pomeroy, Ohio, and at Kanawha, West Virginia, the manufacture of bromine has become of considerable importance. The production in 1870 was 126,000 lbs. In 1867 the production at Stassfurt was 20,000 lbs. The cost in the United States in 1870 was \$1 50 a pound.—The preparation of bromine is conducted, according to Professor Miller, in the following manner: The mother liquor from the brine, after all the salts separable by crystallization have been removed, is subjected to a current of chlorine, care being taken to avoid an excess of this gas, which would occasion inconvenience by forming a compound with the liberated bromine. All the bromides are readily decomposed by chlorine, the attractions of chlorine being more powerful than those of bromine. In the foregoing operation chloride of magnesium is formed, and bromine is set free: $\text{MgBr}_2 + \text{Cl}_2 = \text{MgCl}_2 + \text{Br}_2$; the bromine shows itself by giving to the liquid a beautiful and characteristic yellow color. This yellow liquid, when agitated with ether, parts with its bromine, which is dissolved by the ether. If the mixture is allowed to stand in a glass globe closed at the bottom, the ether rises to the surface, where it forms a beautiful golden yellow layer. The mother liquor is drawn off by opening the stopcock, and the ethereal solution is agitated with a solution of hydrate of potash; the yellow color immediately disappears; bromide and bromate of potassium are formed and dissolved in the water: $3\text{Br}_2 + 6\text{KHO} = \text{KBrO}_3 + 5\text{KBr} + 3\text{H}_2\text{O}$; while the ether, after repose, rises again to the surface despoiled of its bromine, and may again be

employed in a repetition of the process upon a fresh quantity of bitters. When the solution of potash has, by repeated charges of bromine, been nearly neutralized, the liquid is evaporated to dryness; the saline mass is gently ignited, to decompose the bromate; after which it is mixed with peroxide of manganese, and distilled in a retort with sulphuric acid. Dense red vapors of bromine pass over, which may be collected in a receiver containing water, and kept cool by ice. The decomposition is of the same nature as that attending the liberation of chlorine from sea salt by means of oxide of manganese and sulphuric acid: $2\text{KBr} + \text{MnO}_2 + 2\text{H}_2\text{SO}_4 = \text{K}_2\text{SO}_4 + \text{MnSO}_4 + 2\text{H}_2\text{O} + \text{Br}_2$. In this operation a small quantity of chlorine passes over with the bromine, since, from the manner in which the bromide of potassium is formed, it is always contaminated with a portion of chloride of potassium. The chlorine unites with part of the bromine, forming chloride of bromine, which is partially decomposed and dissolved by the water in the receiver, while the bromine is condensed in red drops. In order to obtain bromine free from chlorine, it must be saturated with hydrate of baryta, which produces a mixture of bromide and chloride with bromate of barium; this mixture must be heated to redness in order to convert the bromate into bromide of barium, and the residue digested in alcohol, which dissolves nothing but the bromide; the bromide of barium is obtained by evaporation of its alcoholic solution, and when heated with black oxide of manganese and sulphuric acid, it yields pure bromine.—Bromine forms a red liquid, so deep in color as to be nearly opaque. It has a specific gravity of 2.966 at 60°; it is very volatile, and emits dense red vapors resembling peroxide of nitrogen in color. It resembles chlorine in smell, and is extremely irritating to the nose and fauces when respired, even if largely diluted with air. When swallowed it operates as a powerfully irritating poison; it acts rapidly on all the organic tissues, and renders the skin permanently yellow. Bromine boils at 145.4° F., and when exposed to a temperature of 9.5° it forms a red crystalline solid. The properties of bromine greatly resemble those of chlorine, though they are less strongly developed. It bleaches many vegetable colors. Its vapor will not support the flame of a burning taper. Bromine is slightly soluble in water, and gives to it a yellow color; it also forms with it a hydrate ($\text{Br}_5\text{H}_2\text{O}$) which crystallizes in octahedra at 32° F. This aqueous solution of bromine is decomposed by sunlight into hydrobromic acid and oxygen. Alcohol dissolves bromine freely, and ether does so still more abundantly. Olefiant gas is rapidly absorbed by liquid bromine, and a liquid compound ($\text{C}_2\text{H}_4\text{Br}_2$), bichromide of ethylene, is formed. Bromine combines directly with phosphorus, and with many of the metals, forming compounds termed bromides, the act of combination being often attended with ignition, as

in case of antimony and of tin; even gold combines with it, though slowly; its compound with silver furnishes a material of considerable value in photographic operations. Bromine resembles chlorine in its power of combining with hydrogen and forming with it a very powerful acid. The oxyacids of bromine are, with the exception of bromic acid, nearly unknown, and this compound even has never been obtained in the form of anhydride. Bromide of nitrogen is an oily-looking liquid, resembling chloride of nitrogen in its explosive properties. Bromine is employed in the manufacture of aniline colors, and its compounds are extensively used in medicine and photography. Bromoform, analogous to chloroform, has been prepared by chemists, and used to a slight extent as an anæsthetic. The hydrate of bromal has also been experimented upon as a hypnotic.

BROMLEY, a market town and parish of England, in the county of Kent, 10 m. S. E. of London; pop. in 1871, 5,924. It consists chiefly of one long and neatly built street, contains some good houses, a well endowed school, a handsome college, founded by Bishop Werner in 1666 for the residence and support of 40 clergymen's widows, and a Gothic church, containing the tomb of Dr. Johnson's wife.

BROMME. I. Traugott, a German traveller and bookseller, born at Anger, near Leipsic, in 1802, died Dec. 4, 1865. He settled in the United States in 1820, travelled extensively in Texas and Mexico, cruised in the West Indies as surgeon of a Colombian war schooner, and was detained at Hayti for a year as prisoner, but with permission to explore the island. Released and indemnified by the Colombian government, he returned to Germany, where he became a partner in Walther's publishing house at Dresden, and wrote a number of books on his travels in the new world. His *Hand- und Reisebuch für Auswanderer nach Nord-, Mittel und Süd-Amerika*, has passed through many editions. Transferring his establishment to Stuttgart in 1844, he continued to devote his attention, though not exclusively, to the same class of publications. **II. Karl Rudolf**, brother of the preceding, born at Anger in 1804, died at St. Magnus, near Bremen, Jan. 9, 1860. He acquired distinction as a naval engineer, and having explored the greater part of the old and the new world, and made some new inventions and improvements in naval batteries, he received an appointment in the Greek navy in 1827, as first lieutenant. He was eventually promoted to the command of a corvette and despatched to Candia to escort the Christian fugitives back to Greece. He projected the establishment of a naval academy, which was joined to the royal military academy, and both institutions were placed under his direction. In 1848 he was summoned to Frankfort to take part in the organization of the projected German fleet, and was appointed rear admiral of the German navy. After the dissolu-

tion of the fleet he engaged in writing his memoirs. In 1857 he accepted employment in the Austrian service, as engineer-in-chief in the navy, at Milan. He wrote several nautical and mathematical works in German, French, and English; also, under the *nom de plume* of C. K. Termo, *Skizzen aus dem Leben eines Seemanns* (1832).

BROMOFORM, CHBr_3 , a chemical compound analogous to chloroform, in which 8 atoms of hydrogen are replaced by 3 atoms of bromine. It is a colorless liquid, sp. gr. 2.18, with an agreeable odor and sweetish taste. It possesses anæsthetic properties, but cannot be recommended for that purpose as a substitute for chloroform. It is produced by the simultaneous action of bromine and caustic potash on wood-spirit, alcohol, or acetone.

BROMSGROVE, a town of Worcestershire, England, 12 m. S. S. W. of Birmingham; pop. in 1871, 13,739. It is situated in a highly cultivated valley, on the river Salwarp, near the Birmingham and Worcester canal. The principal church has a fine tower and spire, and contains many ancient monuments of the Talbot-Shrewsbury family; an inscription from one of them, erected to the memory of the great Lord Talbot, who died in 1453, and his two wives, was in 1871 given in evidence in the great Shrewsbury case. The town contains several places of worship and a free grammar school. Nails, buttons, and needles are manufactured here; and in the adjoining parish of Stoke Prior are famous salt and alkali works. In the reign of Edward II., when the linen trade was extensive, the town returned two members to parliament; but on the decline of that trade, the inhabitants asked to be relieved from representation in parliament.

BRONCHI (Gr. *βρόγχος*, the windpipe), the two main branches into which the trachea divides, at the upper part of the chest, in passing to the lungs. They are nearly cylindrical tubes composed of a series of cartilaginous rings, connected with each other by a strong fibro-elastic membrane and lined by a continuation of the mucous membrane of the trachea. The cartilaginous rings serve to keep the bronchi open and pervious for the passage of the air in inspiration. Immediately before entering the lungs each of the bronchi divides, the right into three branches, the left into two, corresponding with the number of lobes of the right and left lung respectively. These branches themselves afterward divide and subdivide in the interior of the lungs, forming the "bronchial tubes," which finally convey the air to the pulmonary lobules and air vesicles.

BRONCHITIS, an inflammatory affection of the mucous membrane lining the bronchial tubes. As it ordinarily occurs, this disease is limited to the larger bronchial tubes, the inflammation often not extending beyond the primary bronchi and the divisions of these which are situated exterior to the lungs. The inflammation may be either acute, subacute, or

chronic. By German and French writers, inflammation here, as in other mucous membranes, is called *catarrh*. The term *bronchial catarrh* means neither more nor less than inflammation of the bronchial mucous membrane, or bronchitis. Acute or subacute bronchitis is the affection popularly known as a cold in the chest. It is generally preceded by an inflammation of the mucous membrane lining the nostrils (*coryza*), and not infrequently by inflammation of the pharynx (*pharyngitis*) and of the larynx (*laryngitis*). In a certain proportion of cases, however, the inflammation attacks the bronchial membrane without affecting the parts situated above. The extension of inflammation from the mucous membrane above the bronchial tubes to the latter may often be prevented by an opiate at bedtime, followed by a hot, stimulating drink to excite free perspiration. The Russian or Turkish bath, also, seems sometimes under these circumstances to prevent the supervention of bronchitis. In acute bronchitis the inflammation, limited to the larger tubes, gives rise at first to a dry cough, which is especially excited by breathing cold air, and by taking a deep inspiration. The cough is usually loud and sonorous. There is a sense of soreness and of constriction on coughing, felt beneath the sternum or breast bone. The expectoration at first is small, viscid, and not infrequently streaked with blood. There is little or no embarrassment in breathing; the patient does not suffer from a sense of the want of air, and the respirations are little if at all increased in frequency. There is only slight fever, as denoted by the pulse and the thermometer in the armpit. The lassitude and debility are often not sufficient to lead the patient to take to the bed. Chilly sensations followed by flashes of heat occur, and the appetite is more or less impaired. In from two to four days the expectoration becomes more or less abundant; and it now consists of solid masses (*sputa*) of a yellowish or greenish color. The acts of expectoration are easier. The cough is said to be loose. The substernal soreness and constriction diminish; and the fever, together with other evidences of constitutional disturbance, gradually disappears. The duration of the affection is from six to twelve days. The symptoms are essentially similar in acute and subacute bronchitis, except that in the latter they are less marked. Subacute bronchitis occasions so little local and general disturbance as rarely to lead persons to remain within doors.—In acute bronchitis it is prudent, if not necessary, for patients to keep within doors; and confinement to the bed for a few days is sometimes judicious. A saline purgative is often serviceable. Moderate counter-irritation to the chest, as by the application of mustard, is useful. Anodynes to allay cough, and remedies promoting gentle perspiration, afford relief, and hasten the progress toward recovery. The Russian bath, if available, may be resorted to with advantage;

and the inhalation of warm vapor promotes expectoration and affords relief. After infancy an ordinary bronchitis is never of itself dangerous. If it prove a serious affection, it is in consequence of its occurrence in connection with other and graver diseases, or in persons enfeebled by age or other causes. In such cases, the danger connected with the bronchitis relates chiefly to the inability to expel the mucus from the bronchial tubes by coughing. If the efforts for expectoration are ineffectual from any cause, the inflammatory products may accumulate within the tubes sufficiently to obstruct the free passage of air to the air cells, and consequently to destroy life by interference with the function of respiration. In early infancy it is sometimes a grave affection in consequence of a greater liability to obstruction of the bronchial tubes, and the occurrence of collapse of pulmonary lobules as a result of this obstruction. These effects are more liable to occur in infants, on account of their feebleness, and the want of voluntary efforts to expectorate.—Bronchitis, excepting where it is secondary to some other pulmonary disease, belongs in the class of affections called symmetrical; that is, the bronchial tubes in each side of the chest are equally affected. It is, in other words, a bilateral disease. As implied in the popular name, "a cold," it is generally attributed to exposure to atmospherical changes in temperature. In certain cases it seems clearly to be thus produced. A continued current of air upon a portion of the body is especially apt to produce it. From its frequent occurrence, however, when it cannot be traced to exposure to cold, and from the fact that a considerable number of persons are often affected simultaneously, the disease not prevailing sufficiently to be called an epidemic, it may be reasonably inferred that the causation involves the presence in the atmosphere of some morbid agency not yet ascertained.—Owing to a peculiar susceptibility of the mucous membrane of the air passages, constituting a curious idiosyncrasy, some persons are affected by bronchitis, often associated with asthma, during the summer season; the cause being evidently vegetable emanations in the atmosphere, as these persons escape an attack on going to sea or to places where there is little or no vegetation. As thus produced, the affection is known as hay bronchitis, hay asthma, and hay fever. The emanations are however by no means derived exclusively from hay. The powder of *ipecacuanha*, emanations from feathers, &c., give rise to bronchitis, usually accompanied with asthma; in some persons, irritating gases or vapors when inhaled are traumatic causes. It is an important fact that the liability to "take cold" is as a rule less in proportion as the habits involve out-of-door life.—In medical practice, ordinary bronchitis is to be discriminated from other inflammatory affections giving rise to cough and expectoration, with fever and other symptoms denoting constitutional disturbance. With refer-

ence to this discrimination, in addition to points of contrast relating to the symptoms, the physical signs obtained by auscultation and percussion are to be taken into account. In general terms, the diagnosis rests on the absence of the signs which belong to the clinical history of other affections with which this is liable to be confounded. In ordinary bronchitis, the resonance or percussion is normal; the murmur of respiration may be weakened, but it is not otherwise altered; the vocal signs are the same as in health. In short, the only signs belonging to the disease are the dry and moist bronchial rales, and these are often wanting. Physical exploration of the chest is important as enabling the physician to determine that other affections are not present, the diagnosis being thus reached "by way of exclusion."—In chronic bronchitis the inflammation is subacute, and more or less persisting. The duration is extremely indefinite; the disease may continue for months or years, and in some cases it becomes permanent, lasting until the end of life. The cough varies much in different cases as regards frequency and violence. The matter of expectoration also varies much in quantity and character, sometimes consisting of small, solid pellets raised with difficulty, sometimes being muco-purulent or consisting chiefly of pus, and accompanied sometimes with a serous liquid in abundance. The last named character is distinguished as *bronchorrhœa*. Not infrequently the sputa are streaked with blood. The constitutional symptoms are slight or wanting. Symptomatic fever is rare; the appetite and digestion are often excellent; there is either but little emaciation, or the nutrition may be well maintained, and the muscular strength is but little impaired. The affection is thus not incompatible with fair or even good general health. The causes of chronic bronchitis are obscure, except where it occurs in connection with those valvular lesions of the heart which occasion obstruction to the return of blood to this organ from the lungs. This obstruction involves a pulmonary congestion which tends to maintain, if not to originate, subacute bronchial inflammation. Bronchorrhœa is apt to occur in these cases, and the transudation of serum affords some relief of the pulmonary congestion. With or without this causative connection, an abundant bronchial expectoration, having existed for a long period, becomes sometimes, as it were, an element of health, patients suffering from a sense of oppression when from any cause the expectoration is notably diminished. It follows from the statements just made, that a chronic inflammation of the bronchial tubes is not usually in itself a serious affection. It may however lead to more or less impairment of health, diminishing the ability to resist or recuperate from other and graver diseases. It may even prove the immediate cause of death when, from the feebleness incident to old age or some coexisting grave disease, the ability to expectorate is impaired. Under these circum-

stances, the accumulation which takes place in the bronchial tubes may be sufficient to cause suffocation. Moreover, it proves in some cases remotely serious by leading to other pulmonary affections, namely, emphysema, or dilatation of the air vesicles, and asthma. Chronic bronchitis generally enters into the causation of these two affections. As a compensation, in leading to these affections, it antagonizes another affection of a much graver character, namely, phthisis or consumption. To the latter affection it does not tend even in the cases in which emphysema and asthma do not become developed. Chronic bronchitis is to be differentiated, in medical practice, from phthisis or consumption. In making this discrimination, the physician relies chiefly on the absence of the symptoms and physical signs which should be found if phthisis or consumption existed; that is, he reasons "by way of exclusion."—There are certain remedies which are useful, and sometimes curative, in chronic bronchitis. The iodide of potassium, the muriate of ammonia, the bromides, and balsam of copaiba are remedies, the utility and sometimes the curative power of which experience has established. A sea voyage in warm latitudes may prove signally beneficial, and may effect a cure. Patients residing in a changeable, cold climate, may derive benefit, and perhaps recover, by removing to one more uniform and genial. The cough is sometimes relieved, expectoration facilitated, and permanent improvement effected, by the inhalation of vapor or spray formed from medicated liquids.—The fact that bronchitis is one of the symmetrical diseases has been stated. This is a law of the disease when it is not secondary to some other pulmonary affection. Exceptions to this law obtain when the bronchitis takes place in the course of pneumonia and tuberculous disease of the lungs. Its occurrence as secondary to these affections is quite constant, and under these circumstances the bronchial inflammation may be more or less limited in extent, and confined to one side, that is, unilateral. The disease is then distinguished as "circumscribed bronchitis."—*Capillary Bronchitis*. This is an important variety of the disease produced by an extension of the inflammation from the large bronchial tubes to those of smaller size. It is attended with great danger to life; indeed, in a large proportion of cases, it ends fatally. The danger consists in the obstruction incident to inflammation of the tubes of small size, and caused by the swelling of the inflamed membrane and the presence of mucus. The danger is greater than in pneumonia, which may for the time render useless one half of the pulmonary organs. The interference with the function of respiration is greater in the so-called capillary bronchitis, because this, like ordinary bronchitis, affects equally both sides; that is, it is bilateral, and hence the respiratory function is compromised more than when an entire lung is rendered useless. Death takes place

by suffocation or apnoea. Happily, the affection is rare. It is limited in its occurrence chiefly to children and aged persons. Its duration in fatal cases is from twelve hours to five days. The symptoms denote an affection compromising notably the respiratory function. The respirations are rapid, in children sometimes being from 60 to 70 per minute. The action of the heart is accelerated. Lividity of the lips and face becomes marked in fatal cases. The suffering from a sense of the want of breath, or dyspnoea, is intense. The physical signs enable the physician to discriminate this affection from other affections involving, like this, notable disturbance of respiration. Over both sides of the chest there is found the auscultatory sign of the presence of liquid in the small bronchial tubes, namely, the subcrepitant rale; and with the presence of this sign there are absent the signs representing the morbid physical conditions which belong to the several affections from which this is to be differentiated, pneumonia and pleurisy with effusions being the most prominent of these.—In cases of capillary bronchitis, bloodletting may be resorted to with advantage, if it be not contraindicated by the feebleness of the patient. With the same qualification, emetics are indicated in young children, with a view to promote expectoration. Revulsive applications (sinapisms or stimulating liniments) to the chest are to be employed, together with poultices or the water dressing and an oiled muslin or silk jacket. If available, the inhalation of oxygen gas should be resorted to. Breathing warm vapor facilitates expectoration, and hastens the resolution of the inflammation. Finally, the strength of the patient is to be supported by nourishment and alcoholic stimulants.—*Influenza*. Thus far bronchitis has been considered as a sporadic disease. An epidemic affection commonly known, in different countries as influenza, and by French writers as *la grippe*, is characterized by bronchial inflammation. Its occurrence from time to time has been noted by medical writers for several centuries. It is an epidemic remarkable for its extensive and rapid diffusion, sometimes extending within a brief period over many different and widely separated countries. Influenza differs from ordinary acute bronchitis in the frequent extension of the inflammation to the frontal and maxillary sinuses, the lachrymal ducts and conjunctiva, and the Eustachian tube; but more especially it differs in a greater amount of constitutional disturbance. It is, in fact, to be regarded as a general or constitutional disease, of which the bronchitis is the local manifestation. Like all epidemic diseases, this has doubtless a special cause, and this cause undoubtedly is in the atmosphere. The special cause, however, is independent of appreciable atmospheric changes. Of the nature, source, and mode of diffusion of the cause we have no positive knowledge; but we are equally ignorant of the special causes of many, and indeed of most epi-

demie diseases. That these diseases depend on organic entities is a supposition which at the present time many regard with favor; but this remains to be proved or disproved by further researches. During some epidemics of influenza, a vast number of persons are simultaneously affected. Generally the affection is mild; but it occasions some fatality among the aged and feeble. The fatality, however, is in general due to complications which occur, and of these capillary bronchitis and pneumonia are especially apt to cause death.—*Diphtheritic Bronchitis*. A variety of bronchitis is characterized by a fibrinous exudation, or a deposit of lymph on the inflamed mucous surface, forming what is known as a false membrane. This is called bronchitis with fibrinous exudation, or pseudo-membranous or diphtheritic bronchitis. It occurs in a certain proportion of cases of diphtheria, and also of the affection known as pseudo-membranous laryngo-trachitis or true croup. Irrespective of these pathological connections, it constitutes a very rare variety of bronchitis. The fibrinous exudation or false membrane may extend to a greater or less distance along the bronchial tubes. It is sometimes expectorated entire, presenting complete casts of the bronchial subdivisions from which it was thrown off. A specimen in the museum of the Bellevue hospital medical college, presented by Dr. Stephen Rogers of New York, shows solid casts, composed of concentric layers of fibrine, formed in the bronchial tubes of an entire lobe, extending to those of minute size. The patient from whom this specimen was obtained repeatedly expectorated casts of the same description. Occurring in adults, independently of diphtheria or membranous laryngitis, this variety of bronchitis rarely destroys life. The presence of the exudation cannot be determined prior to its appearance in the matter of expectoration. When the character of the disease is ascertained, the indications for treatment do not differ materially from those in ordinary bronchitis; but the inhalation of warm vapor or spray is useful as a means of promoting the separation and expectoration of the false membrane.

BRÖNDSTED, Peder Oluf, a Danish archaeologist, born near Horsens, Jutland, Nov. 17, 1780, died in Copenhagen, June 26, 1842. He explored Greece in 1810 in company with other savants, and was appointed in 1813 professor at the Copenhagen university, and in 1818 agent of his government at Rome. He afterward explored Sicily and the Ionian islands, and after his return to Copenhagen in 1832 officiated as director of the royal cabinet of antiquities, as professor, and lastly as rector of the university. He left many writings, mostly in German, prominent among which are: *Beiträge zur dänischen Geschichte aus nordfranzösischen Manuscripten des Mittelalters* (Copenhagen, 1817-'18); *Untersuchungen in Griechenland* (Paris, 1826-'30); *Denkwürdigkeiten aus Griechenland* (Paris, 1833).

BRONGNIART. I. Alexandre Théodore, a French architect, born in Paris, Feb. 15, 1789, died there, June 6, 1815. He was the son of an apothecary, and at first studied medicine, but afterward became a pupil of Boulée, a noted architect of the day, whom he soon surpassed. He constructed many public and private edifices, designed and laid out the park of Mau-pertuis, and made numerous designs for ornaments, vases, and furniture. Toward the end of his career he was appointed architect of the Bourse and of Père-la-Chaise. **II. Antoine Louis**, a French chemist, brother of the preceding, died in Paris, Feb. 24, 1804. He was apothecary to Louis XVI., professor at the college of pharmacy, afterward professor of chemistry applied to the arts, and the colleague of Fourcroy at the lyceum of the republic, and also at the *jardin des plantes*.

During a portion of the revolutionary period he was apothecary to the army. He wrote much in the journals of science, and published some important papers on chemistry; among others, *Tableau analytique des combinaisons et des décompositions de différentes substances* (Paris, 1778). **III. Alexandre**, a French chemist and geologist, son of the architect, born in Paris, Feb. 5, 1770, died there in October, 1847. He was early trained to scientific pursuits, and at the age of 20 was occupied in studying the best means of improving the art of enamelling. He was afterward engaged in the medical department of the army, and in 1800 was appointed director of the manufactory of porcelain at Sèvres. In 1807 he published a treatise on mineralogy, which became a standard work. He was also appointed professor of mineralogy at the *jardin des plantes*. He undertook the classification of reptiles, described the trilobites, and assisted Cuvier in the study of the fossil remains of extinct types, by exploring the geological formation of Montmartre and its fossil treasures; their joint labors being published in the celebrated *Description géologique des environs de Paris*. He travelled over the northern and southern parts of Europe, and was the first to give the world, in his *Tableau des terrains qui composent l'écorce du globe* (Paris, 1829), an accurate chronological account of the different superficial strata of the earth's crust. He was elected member of the academy of sciences in 1815, and was connected with the progress of the physical sciences in nearly all their branches during 40 years. In 1845 he published *Traité des arts céramiques*, which is deemed the best work of the kind ever written. **IV. Adolphe Théodore**, a French botanist, son of the preceding, born in Paris, Jan. 14, 1801. He first studied medicine, and received his diploma in 1826, but afterward turned his attention to the physiology of plants and antediluvian phytology. In 1834 he was elected a member of the academy of sciences, as successor to Desfontaines; and in 1839 professor of botany at the museum of natural history in Paris. His researches have been various, and his writings

on fossil vegetables and other branches of his favorite science are numerous.

BRONNER, Johann Philipp, a German writer on wines, born at Neckargemünd, near Heidelberg, in 1792, died at Wiesloch, Dec. 4, 1865. He studied pharmacy, and in 1816 became an apothecary at Wiesbaden, where he devoted himself to the natural sciences and the culture of the vine. In 1831 he established a school for instruction in viniculture. Subsequently, under a commission from the government of Baden, he travelled through Switzerland, Italy, Tyrol, Austria, Moravia, Hungary, Styria, and Bavaria, to investigate this branch of agriculture. Between 1830 and 1857 he published 14 treatises relating to wine and its production.

BRONTË, a town of Sicily, in the province of Catania, near the western base of Mt. Etna, 22 m. N. N. W. of Catania; pop. about 12,000. It has a number of churches, convents, a seminary, manufactures of woollens and paper, and trade in wine, oil, silk, grain, and fruits. In 1799 the Neapolitan government conferred the title of duke of Brontë, with a revenue of about \$18,700 per annum, upon Lord Nelson. The town suffered from an earthquake in 1832.

BRONTË, Charlotte ("Currer Bell"), an English novelist, born at Thornton, Yorkshire, April 21, 1816, died at Haworth, March 31, 1855. She was the daughter of the Rev. Patrick Brontë, a native of Ireland, who shortly before her birth became curate of Thornton church, and in 1820 minister of Haworth. She lost her mother at the age of five. Owing to her father's narrow means, the family were early inured to industry and self-denial, and being, by the habits and circumstances of the place, in a great degree cut off from the ordinary pleasures of childhood, they were accustomed to occupations and amusements beyond their years. In 1824 Charlotte and three of her sisters, Maria, Elizabeth, and Emily, were put to a school at a place called Cowan's Bridge. The situation proved to be unhealthy, and Maria and Elizabeth died the following year from disease contracted there. The hardships suffered at this school from scanty food and severe discipline furnished to a considerable extent the theme of "Jane Eyre." In the autumn of 1825 Charlotte and Emily left the school, and for several years lived at home. During this period Charlotte had the care of the younger members of the family; she spent much of her time in writing, and manifested a development of mind and a compass and facility of thought remarkable in a girl of her age. In the winter of 1831 she was again put to school at a place called Roe Head, where she continued nearly two years. Here she was free from discomforts, save what grew from a tendency to despondency. She cared nothing for play; was quiet and studious, often confounding her schoolmates by knowing things quite out of their range; and sometimes exercised her genius in telling stories for their entertainment. In 1835 she reëntered the school as a

teacher; but the labor wore upon her health and spirits till she was forced to give it up. In 1839 she obtained a situation as governess, but fell into a hard and uncongenial family, from which she soon withdrew. In 1841 she went out again as governess, and met with kind and appreciative treatment; but the occupation was not suited to her disposition. She next determined, in conjunction with her sisters Emily and Anne, to establish a school of her own; and to qualify themselves for the task, she and Emily in the winter of 1842 went to Brussels. At the end of six months they were employed as teachers in the school they were attending. Emily did not remain quite a year, but Charlotte spent nearly two years there. In the summer of 1844 the arrangements were made for opening a school at Halloworth; they sent out circulars, and received many assurances of good wishes to the enterprise, but obtained no pupils. Henceforth the sisters remained at home, dividing their time between household cares and literary labors. In 1846 they issued at their own risk, under the names of Currer, Ellis, and Acton Bell, a volume of poems; but the work met with little favor. Notwithstanding this failure, each of them wrote a prose tale, hoping the three would be published together. These were, "The Professor," by Charlotte; "Wuthering Heights," by Emily; and "Agnes Grey," by Anne; the names assumed in the volume of poems being still retained. The last two found a publisher; the first was everywhere refused, nor did it appear till after the author's death. It was under the weight of all this discouragement that Charlotte undertook the composition of "Jane Eyre," which was published in October, 1847, and met with immense success; it was translated into most European languages, and dramatized in England and also in Germany under the title of "The Orphan of Lowood." Emily, to whom Charlotte had been deeply attached, died Dec. 19, 1848. Anne died May 28, 1849, her novel, "The Tenant of Wildfell Hall," having been published the preceding year. Charlotte's second novel, "Shirley," was published in October, 1849. She had taken great pains with the work, but it hardly made good the expectations raised by "Jane Eyre." From the large use she made of local manners and traditions, the secret of the authorship soon transpired, and she was invited to London, where she was introduced to the prominent literary characters of the time. Her third novel, "Villette," published in 1853, seems to have taken more or less of its shape and texture from the author's recollections of Brussels. In strength and originality of characterization it does not equal "Shirley," but is perhaps more interesting and attractive as a whole. It met with almost unbounded applause. About this time Miss Brontë had an offer of marriage from the Rev. Arthur Nicholls, her father's curate. Mr. Brontë objected to the match, and Mr. Nicholls resigned

his curacy; but by the spring of 1854 Mr. Brontë came to view the matter in a different light, and an engagement was formed. Mr. Nicholls resumed the curacy, and the marriage took place in the following June. They continued to reside at the parsonage until her death. "The Professor" was published some time after the death of the author, and a few chapters of her unfinished novel entitled "Emma" appeared in 1860 in the "Cornhill Magazine," then edited by her friend W. M. Thackeray. A biography of Charlotte Brontë, by Mrs. Gaskell, was published in 1857, and a second edition, considerably modified, in 1858.

BRONZE, an alloy consisting of proportions of copper and tin which vary according to the purpose desired, and to which lead, zinc, and silver are sometimes added for the purpose of giving greater brilliancy to the compound, or rendering it more fusible, the zinc being introduced in the form of brass. In some of the modern bronzes brass is used instead of tin; these are then nothing more than brass consisting of very large proportions of copper. The principal varieties of bronze are speculum metal, bell metal, gun metal, and statuary bronze. Speculum metal of reflecting telescopes is the whitest, hardest, most brilliant, and most brittle of all the bronze alloys; it consists of 100 parts of tin and 215 of copper. Bell metal is usually composed of 78 parts of copper and 22 of tin. This is also the composition of the Chinese gongs, which are forged under the hammer, the alloy being rendered malleable after casting by plunging it at a cherry-red heat into cold water; the plate is kept in shape by confining it between two disks of iron. Cannon metal consists of 90 to 91 parts in 100 of copper, and the rest of tin; the strength of this compound is stated by Dr. Thomson to be one half that of malleable iron. Antique bronze consisted of about 87 parts of copper to 13 of tin. Most of the modern French bronzes are composed of about 91 per cent. of copper, 2 of tin, 6 of zinc, and 1 of lead. The following table gives the composition of several ancient and modern bronzes from various authorities:

BRONZES.	Copper.	Tin.	Other Metals.
Coin of Alexander the Great, 835 B. C.	86-72	13-14	
Ptolemy IX., 70 B. C.	84-25	15-64	Iron, a trace.
Old Attic coin.	88-46	10-04	Lead, 1-05.
Roman coin, 500 B. C.	62-04	7-06	Lead, 29-32.
Celtic weapon.	85-28	13-11	Lead, 1-14.
Celtic vessels.	88-00	12-00	
Egyptian dagger.	85-00	14-00	
Gallo-Roman axe.	77-77	19-61	Lead, 1-15; zinc, 1-44.
Gaulic bell.	85-90	14-10	
Etruscan vessel.	85-00	14-20	Zinc, 0-80.
Chinese gong.	80-50	19-50	
Tam-tams.	78-00	22-00	
Old bell at Rouen.	71-00	26-00	Zinc, 1-8; iron, 1-2.

The qualities of bronze of the same composition depend much upon the temperature of the alloy when poured, and on the rapidity of the cooling.—In making bronze, the metals are melted separately, and the tin is added and the

mixture stirred until it is homogeneous. It is then turned into the mould as quickly as possible, and when the exterior is sufficiently solidified the casting is uncovered, in order, by hastening the setting of the interior, to prevent as much as possible the formation of strata of unequal composition, which is liable to occur from the great difference in the fusibility of the metals, that of copper being above $2,200^{\circ}$ F., while tin melts at 442° . In casting cannon, where there is a great mass of metal, such stratification is liable to occur, the parts which solidify first being richer in copper. This difficulty is largely overcome by the addition of about one tenth per cent. of phosphorus, by which the grain of the bronze is also improved. After cooling, if it is again raised to a temperature of about $1,000^{\circ}$ and allowed to cool slowly, its toughness of texture will be improved. The dark olive hue which bronze acquires by exposure is hastened by the application of oxidizing washes, and different shades may be given according to the chemical qualities of the wash employed. Some extract the tin from the surface, and leave the copper in excess, and others remove the copper and leave the tin most prominent.—Among the ancient Egyptians, Greeks, and Romans, the manufacture of bronze articles was very extensively carried on. In Greece especially the taste for statuary in this material was cultivated to an unparalleled extent. The wealth of some cities was estimated by the number of their statues. In Athens alone no fewer than 3,000 statues have been found, and in Rhodes, at Olympia, and in Delphi many more. The famous colossuses were cast of this alloy. The names of many of the ancient artists are still celebrated, and their groups of statuary continue to be our models. The alloy was employed by them for purposes to which we apply the harder metals, as in some periods for their arms and armor, medals, and even their surgical instruments, a set of which was discovered at Pompeii. By them it was regarded as a sacred metal, and endowed with a mysterious power of driving away evil spirits. The laws were inscribed on tables of bronze, and upon bronze coins alone were placed the words *moneta sacra*. The Phœnicians were the first known workers of it; they made it into plates, which were nailed together; and they also cast it solid, and cored. The Athenian sculptor Myron employed it of a pale color and unknown composition, in the 5th century B. C. The Corinthian bronze is supposed to have been suggested by the accidental fusing of metals at the burning of Corinth, 146 B. C.; it was of three colors, white, yellow, and the last not known. The antique liver-colored cinque-cents, and the Florentine bronze, are of the same shade, approaching a dull reddish brown.—Aluminum bronze is composed of 90 parts of copper and 10 of aluminum. It resembles gold, and is used in ornaments.

BRONZING, the process of covering articles of wood, clay, plaster, metals, ivory, &c., with

compositions which give to them the appearance of bronze. These compositions vary in their ingredients, and the process also, with the articles to be coated. An application is first made of size or oil varnish, into which when nearly dry a metallic powder is rubbed, or this may be previously mixed with the varnish. This powder is most commonly a preparation called gold powder, prepared as follows: Gold leaf is ground together with honey upon a stone. When thoroughly mixed, and the particles of gold completely reduced, the preparation is stirred up in water, and washed until the honey is entirely removed. The gold which settles is then collected upon filtering paper and dried. Another variety of powder, called *aurum mosaicum* or *musivum*, is prepared in the following manner: A pound of tin, melted in a crucible, is amalgamated with half its weight of pure mercury. When the amalgam is cold, it is reduced to powder, and ground with $\frac{1}{2}$ lb. of sal ammoniac and 7 oz. of sulphur. On subliming this mixture in a matrass, the tin remains at the bottom of the vessel in a flaky golden powder, which is the *aurum mosaicum*. A shade of red is given to this when desired, by adding a small portion of red lead. Copper powder is obtained for the same purpose by the precipitation of the metal from its solution in nitric or sulphuric acid, by means of pieces of metallic iron. The copper deposits itself upon these, from which it may be brushed off in powder, care being taken to exclude it from the action of the air as it is washed in water, or better in alcohol. It is used either alone or mixed with pulverized bone ash. The preparation called gold size is also used in bronzing. It is made by boiling 4 oz. of powdered gum animé and a pound of linseed oil, the gum being gradually added, and stirred into the oil while this is heated. The boiling is continued till the mixture becomes thicker than tar. This is then to be strained through a coarse cloth. When applied, vermilion is added to render it opaque, and a convenient consistency is given to it with oil of turpentine. After being applied, it is allowed to dry very nearly, and when it has become sufficiently hard the powder selected is rubbed over the work with a piece of soft leather wrapped round the finger; or the application is better made with a soft camel's hair pencil, with which, when quite dry, the loose powder is brushed away. If gold size is not to be used, the powders may be mixed in gum water and laid on with a brush.—Vinegar is often applied to brass castings to give them the green bronze color, sometimes in combination with sal ammoniac and sometimes with common salt. Coins and medals are sometimes bronzed with a solution of verdigris and sal ammoniac in vinegar, which is afterward diluted with water and boiled, and applied while hot. It is said that the Chinese bronze copper vessels by taking 2 parts of verdigris, 2 of cinnabar, 5 of sal ammoniac, and 5 of alum in powder, making a

paste with vinegar, and laying this on the brightened metal, which is then held over a fire, and afterward cooled, washed, and dried; the operation being repeated till the desired color appears. The cinnabar produces a thin coat of sulphuret of copper on the surface of the metal. New bronze articles may be made to assume an antique appearance by the repeated application of a solution of 4 parts of sal ammoniac, 1 of binoxalate of potash, and 50 of vinegar; the application should be made with a soft rag, and the article rubbed with it till dry. The best bronzing liquid to apply to copper, brass, new bronze, or iron is a solution of chloride of platinum; almost any bronze tint may be produced with it, according to the number of applications or the strength of the solution.—Mr. Hiram Tucker of New York has invented a process for bronzing cast iron, which consists in covering the cleaned or polished surface of the iron with a vegetable oil, and subjecting the article to a degree of heat which will decompose the oil without charring it. By this means the surface of the iron becomes oxidized in such a manner as to cause it to have a close resemblance to real bronze. It is said to possess considerable durability, and as cast iron has the quality of filling the mould completely and making a fine casting, the invention will probably prove of much value in the arts. Bronzing and browning gun barrels, and other articles of iron, is effected by first thoroughly rusting the surface by an application of chloride of antimony, mixed with olive oil, and rubbed upon the iron slightly heated. The operation is hastened by subsequent rubbing with dilute nitric acid. This, or dilute muriatic acid, is sometimes used instead of the chloride of antimony. The barrel is then well cleaned, washed with water, dried, and finally polished with a steel burnisher, or rubbed with wax, or varnished with a very weak solution of shellac and alcohol.

BROOKE, a N. county of West Virginia, forming part of the narrow strip between Pennsylvania and Ohio, called the Panhandle; area, 75 sq. m.; pop. in 1870, 5,464, of whom 97 were colored. It is watered by small creeks that fall into the Ohio. The soil is fertile and the surface hilly. The Pittsburgh, Cincinnati, and St. Louis railroad passes through the county. The chief productions in 1870 were 45,884 bushels of wheat, 185,576 of Indian corn, 81,135 of oats, 14,112 of barley, 45,850 of potatoes, 7,570 tons of hay, 110,307 lbs. of butter, and 185,105 of wool. There were 1,280 horses, 1,060 milch cows, 1,509 other cattle, 46,581 sheep, and 2,920 swine. Capital Wellsburg.

BROOKE, Frances, an English authoress, wife of the Rev. John Brooke, died in 1789. She wrote sonnets, translations, novels, and tragedies. Her best work, the "History of Emily Montagu" (1769), contains fine descriptions of the scenery of Canada, where she resided for some time. Of her dramas, "Rosina," acted at Covent Garden in 1782, was the most successful.

BROOKE. I. Francis J., an American magistrate, born in Virginia, Aug. 27, 1763, died March 3, 1851. He was an officer of the revolution, and an intimate friend of Washington. At 16 he was appointed lieutenant in Gen. Harrison's regiment of artillery, and served his first campaign under Lafayette. He afterward joined the army of Gen. Greene, and was at Charleston at the end of the war. He was admitted to the bar in 1788, was repeatedly elected to the legislature of Virginia, and was a judge from 1804 to the end of his life. **II. Francis J.**, son of the preceding, died Dec. 25, 1837. He joined the army in 1822, and fell in the battle of Okeechobee, Fla., in which he took a distinguished part. **III. George Mercer**, brother of the judge, died at San Antonio, Texas, March 9, 1851. Having entered the military service in 1808, he was promoted to the rank of lieutenant colonel, Aug. 15, 1814, for his brave conduct in the defence of Fort Erie, in which he was wounded. He fought with distinction in the war with Mexico, and in 1848 was made major general.

BROOKE, Henry, an Irish novelist and dramatist, born at Rantavan in 1706, died in Dublin, Oct. 10, 1783. A poem, "Universal Beauty," introduced him to Swift and others, including the prince of Wales (father of George III.), to support whom in his antagonist position to his father Mr. Brooke is said to have written, in 1738, the tragedy of "Gustavus Vasa." The licenser of plays, believing that it was directed against Sir Robert Walpole, forbade its performance after it had been rehearsed at Drury Lane theatre; but the play was published, and brought the author £1,000. In 1745, when the rebellion broke out in Scotland, he wrote the "Farmer's Letters," which were believed to have greatly influenced the Irish against taking up arms for the Stuarts. An opera, called "Jack the Giant Killer," which was to have been produced soon after the close of the rebellion, was prohibited by the Irish government, who feared that it might be taken as a reflection on the duke of Cumberland, but he obtained £800 by its publication; at the same time he was appointed barrackmaster of Mullingar by Lord Chesterfield, the viceroy. In 1752 his tragedy, "The Earl of Essex," was successfully played in Dublin, and in 1762 at Drury Lane theatre. His novel entitled "The Fool of Quality" has had considerable celebrity. He also translated a part of Tasso's *Gerusalemme liberata*.

BROOKE, Sir James, rajah of Sarawak, born in Bengal, April 29, 1803, died in Devonshire, England, June 11, 1868. His father, having taken up his residence at Bath, England, procured for him a cadetship in the East India service. He received a severe gunshot wound in the chest at the storming of a stockade in the Burmese war, and was forced to return to England. He travelled on the continent, and found on his return to India in 1830 that he had exceeded his leave of absence and for-

feited his appointment. On a voyage from Calcutta to China he conceived the idea of establishing a civilized power among the islands of the Indian archipelago. He returned to England, purchased a yacht out of the royal squadron, enjoying the same privileges as a man-of-war, and sailed for the East in October, 1838. On his arrival at Sarawak, on the island of Borneo, he found the country in a state of warfare, the Dyaks, its inhabitants, carrying on a losing contest. To secure his assistance, the rajah offered to make Brooke his successor, and give him the command of the army. Established in authority over Sarawak, after defeating the hostile forces with great ease, he endeavored to accustom the inhabitants to a regular government, and to turn them from piracy and local war to agriculture and trade, in which he succeeded to an extraordinary degree. In conjunction with the English naval commanders he attacked, routed, and extirpated the Malay pirates of the archipelago. Though independent of the English, and holding the dignity of rajah by appointment from the sultan of Borneo, when his conduct was attacked in England, he visited that country in 1847 to vindicate himself. He was successful, was knighted, and received the title of governor of Labuan, a salary of £2,000, and a staff of subordinate officers under British pay. From this office, however, he was removed after a subsequent visit to England. His rule was greatly for the benefit of his people. He compiled a code of laws, opened trade, made roads, and provided for the security of property. Upon the breaking out of the war of England with China in 1857, his residence was suddenly attacked by a body of 4,000 Chinese, and he escaped only by swimming the river. The Dyaks rallied to his support, and in a short time he fell upon the Chinese, and routed them with a loss of half their number. The following year he returned to England and took up his residence in Devonshire. He suffered much from the attacks of his enemies in parliament. In 1861 he made two voyages to Borneo, to suppress an insurrection and settle the government, which he left in charge of his nephew, though he retained the title and authority of rajah until his death. Portions of his journals have been published, and the "Private Letters of Sir James Brooke, K. O. B., from 1838 to the present Time" (3 vols., London, 1858).

BROOKINGS, a S. E. county of Dakota, bounded E. by Minnesota, and intersected by the Big Sioux river; area, 750 sq. m.; pop. in 1870, 163, of whom 145 were civilized Indians. The eastern and central portions are watered by streams flowing into the Minnesota river and the Big Sioux, and by numerous lakes; the N. W. portion is mountainous.

BROOKLINE, a town of Norfolk co., Mass., 5 m. S. W. of Boston, of which it is a suburb; pop. in 1870, 6,650. Almost the whole town is occupied by beautiful country resi-

dences. It contains one of the reservoirs for supplying Boston with water, which covers 88 acres, the water surface being about 22½ acres, and the capacity about 100,000,000 gallons.

BROOKLYN, capital of Kings county, New York, the third city in the United States in point of population, on the W. end of Long Island, opposite New York city, and separated from it by the East river, an arm of the sea connecting the bay of New York with Long Island sound; lat. of the navy yard, 40° 41' 50" N., lon. 73° 59' 30" W. The exterior line of the city measures 22 m., embracing an area of 13,387 acres, or 20·84 sq. m., of which 6·48 sq. m. are devoted to streets and alleys. Beginning at the northeast, its boundaries are Newtown creek and Queens county, the towns of New Lots, Flatbush, and New Utrecht in Kings county, the bay of New York, and the East river. Its extreme length from N. to S. is about 7½ m., and its greatest breadth 5 m.; the average breadth, however, is only about 3½ m. The western boundary of the city affords 8½ m. of water front. Newtown creek, an irregular arm of the bay, receiving several small fresh-water streams, is navigable for a mile or two from the East river for vessels of light draught. Wallabout bay is a deep indentation lying in the section known as Wallabout, between the old cities of Williamsburgh and Brooklyn. Gowanus bay extends into the southern part of the city. Opposite South Brooklyn is Governor's island, between which and the shore is Buttermilk channel, about a quarter of a mile wide, in early times fordable by cattle, but now navigable for the largest vessels. The portion of land between Buttermilk channel and Gowanus bay is known as Red Hook point. Brooklyn is for the most part considerably elevated above tide water. The S. and E. borders are occupied by a broad range of low hills; a large portion of the S. part of the city is low and level. Along the East river S. of Fulton street is an irregular bluff, 70 ft. above the level of the sea, known as Brooklyn Heights. It is thickly built upon, and affords a magnificent view of the city and bay of New York. The city embraces several districts still locally known by the names which they bore when they were distinct municipalities. Brooklyn proper includes the older portion of the city S. of Wallabout, and the part of this lying S. of Atlantic avenue is known as South Brooklyn. Williamsburgh includes the thickly settled portions N. of Division avenue. Bushwick occupies the N. portion of the city E. of Williamsburgh. In the vicinity of Wallabout bay is Wallabout, adjoining which is the section called East Brooklyn. Greenpoint lies between Bushwick and Newtown creeks, occupies the extreme N. E. part of the city, and forms the 17th ward. Gowanus is the name of that portion of the city which has grown up around Gowanus bay. Bedford and New Brooklyn are localities in the E. part of the city, formerly separate villages. The city is legally divided into the Eastern District, embracing

Williamsburgh, Bushwick, Greenpoint, and the 19th ward (formerly a part of Wallabout), and the Western District, comprising the old city of Brooklyn, including the first 12 wards and the 20th to the 25th ward. Opposite Greenpoint, and separated from it by Newtown creek, is Hunter's Point, now included in the municipality of Long Island City. Adjoining the S. E. extremity of the city is the large village of East New York, and on the S. W., bordering on Prospect park, is that of Flatbush.—For many years after its settlement Brooklyn was merely a hamlet, but since its incorporation as a city its growth has been remarkably rapid. In 1698 the population was 509. In 1706 there were 64 freeholders; 96 years later the number had only increased to 86. The progress of population in the present century has been as follows: 1800, 3,298; 1810, 4,402; 1820, 7,175; 1830, 15,292; 1840, 36,233; 1845, 59,574; 1850, 96,850; 1855 (including Williamsburgh and Bushwick, previously separate), 205,230; 1860, 266,661; 1865, 296,378; 1870, 396,099. Of the population in 1870, 144,718 were foreigners and 4,944 were colored. Of the natives, 219,774 were born in the state of New York, 6,009 in New Jersey, 5,711 in Massachusetts, 5,264 in Connecticut, and 3,294 in Pennsylvania. Of the foreigners, 79,985 were natives of Ireland, 36,771 of Germany, 18,843 of England, 4,099 of Scotland, 2,806 of British America, 1,894 of France, and 1,105 of Sweden.—Brooklyn possesses many advantages as a place of residence. For the most part considerably elevated above tide water, it is open on all sides to the land and sea breezes, while its wide streets, generally at right angles to each other, afford a free circulation of air. Several avenues 100 ft. wide have been formed, connecting distant points. On the Heights are many fine residences occupied by leading merchants of New York. Of the streets, perhaps Clinton avenue is the most attractive; it is lined with beautiful residences surrounded with extensive ornamental grounds. In the 21st ward many costly dwellings have recently been erected. The principal business thoroughfare is Fulton street, extending about 5 m. from Fulton ferry to East New York; until recently the portion above the city hall was designated as Fulton avenue. Myrtle avenue, extending E. from Fulton street near the city hall, is also a prominent business thoroughfare. Extending from South ferry to East New York, and parallel with Fulton street from near the city hall, is Atlantic avenue, an active business street in its lower part, and in its upper shaded by double rows of trees. Within a few years the business centre has extended from near the foot of Fulton street to the vicinity of the city hall, where are now situated most of the monetary and insurance interests, &c. The great commercial interests are along the river front.—The public buildings of Brooklyn are not remarkable for their imposing size or architecture. The city hall, at the junction of Fulton, Court, and Joralemon streets, is of white marble in the Ionic

style, with six columns supporting the roof of the portico; its dimensions are 162 by 102 ft., and 75 ft. in height, comprising three stories and a basement; it is surmounted by a tower, the top of which is 158 ft. from the ground; it was built in 1845-'6, and its entire cost was about \$200,000. The county court house, fronting on Fulton street near the city hall, is 140 ft. wide and extends 315 ft. back to Livingston street; it is 64 ft. high, and is surmounted by a cupola composed of ribs and panel work of iron, rising 104 ft. above the street; the main edifice is constructed of Westchester marble in the Corinthian style of architecture; it was erected in 1862, at a total cost of \$543,000. The county jail in Raymond street is a heavy-looking castellated Gothic edifice of red sandstone. The penitentiary is in Nostrand avenue, on the border of the city. The state arsenal is in Portland avenue near Washington park. The post office is a rented building in Washington street near the city hall; there are sub-stations in Williamsburgh and Greenpoint. The academy of music in Montague street, near the city hall, was erected in 1860 at a cost of \$206,000; it is built of the best quality of brick with Dorchester stone trimmings, 282 ft. long, 92 ft. wide, and 56 ft. high, and is capable of seating 2,300 persons. Adjoining the academy is the fine edifice of the art association, while opposite is the elegant building of the mercantile library, erected in 1868 at a cost of more than \$150,000. The city hospital, on elevated ground in Raymond street near De Kalb avenue, is of brick with stone dressing; it has a front of 200 ft. facing Raymond street, and consists of a main building four stories high, 52 ft. in width and depth, with a rear extension of 30 ft., and two wings, each 74 ft. long, 56 ft. deep, and three stories high. Among other noticeable buildings may be mentioned the iron structure of the Long Island safe deposit company on the corner of Front and Fulton streets, erected in 1868 at a cost of \$150,000; the building occupied by the young men's Christian association, in Fulton street, corner of Gallatin place; and the elegant building of the Williamsburgh savings bank, corner of Broadway and Fifth street, completed in 1875 at a cost of \$500,000. Ground has been purchased on the corner of Clinton and Remsen streets on which to erect a costly building for the Long Island historical society.—From the great number of church edifices, Brooklyn is often called the city of churches. Among the more prominent of these is St. Ann's (Episcopal), with its adjoining chapel, on the corner of Clinton and Livingston streets, erected in 1868 at a cost of about \$200,000; it is constructed of Belleville and Cleveland stone in the middle pointed Gothic style, 126 ft. long, 75 ft. wide, and 90 ft. high, and can seat 2,400 persons. The church of the Holy Trinity (Episcopal), a brown stone edifice in the Gothic style, on the corner of Clinton and Montague streets, was erected in 1847 at a cost, including chapel, of about \$175,000. The

spire, recently completed at a cost of \$55,000, is the highest in Brooklyn, being 275 ft. high, and of great architectural beauty. St. Paul's (Episcopal), corner of Clinton and Carroll streets, is a Gothic structure of rough-hewn blue granite, handsomely relieved with sandstone; it has a front of 75 ft., a depth of 145 ft., and is 67 ft. high in the nave; it has seats for 1,000, and cost \$150,000. The church of the Pilgrims (of which the Rev. Dr. R. S. Storrs has been pastor since 1846), corner of Henry and Remsen streets, is of gray stone, its tall tower and spire forming a commanding object to those approaching the city from the bay. Inserted in the main tower, about 6 ft. from the ground, may be seen a piece of the "Pilgrim Rock," from Plymouth, Mass. Plymouth church (Congregational), in Orange street, between Hicks and Henry streets, is a plain brick structure with accommodations for 2,800 persons, and containing the largest church organ in America, which was built in Boston. The Rev. Henry Ward Beecher has been the pastor since 1847. The amount realized from the rental of pews for 1873 was \$60,230. The Second Reformed church, in Pierrepont street near Monroe place, is of brown stone in the Roman Corinthian style, with a depth of 100 ft. and a front of 70 ft., having a portico supported by Corinthian pillars. A Roman Catholic cathedral is in process of construction, which is to occupy the entire block bounded by Greene, Lafayette, Vanderbilt, and Clermont avenues; when completed it will be one of the largest church edifices in the United States. Among other churches of marked appearance may be mentioned Grace (Episcopal), in Hicks street; Christ (Episcopal), corner of Clinton and Harrison streets; the Methodist church corner of Clermont and Willoughby avenues, erected in 1868 at a cost of \$75,000; and the new edifice of St. Charles Borromeo (Roman Catholic), in Sidney place, which cost \$75,000.—One of the most important elements in the prosperity of the city is Prospect park, the construction of which was begun in 1866, from plans and under the superintendence of Olmsted, Vaux and co., who also laid out Central park, New York. The site chosen is a portion of an elevated ridge in the S. W. part of the city, adjoining Flatbush, and commands a magnificent view of the cities of New York and Brooklyn, the inner and outer harbor, Long Island, the Jersey shore, and the Atlantic. This spot affords unusual natural advantages by its wooded hills and broad meadows. The park, with the adjoining parade ground, contains 550 acres. The ground was beautifully shaded by old woods, which have been skilfully improved. A great many large trees have been transplanted to the park, which already has the characteristics of an old pleasure ground, and is very attractive. The main entrance, at the junction of Park, Flatbush, and Vanderbilt avenues, is a large ellipse called the plaza, containing a fountain and a statue of Abraham Lincoln. A lake

about 50 acres in extent, surrounded by a beautiful driveway, is in process of construction, and when completed will contain a large fountain. Among other prominent features included in the design are zoological gardens to cover 25 acres, and a grand observatory on Lookout hill. Seven miles of driving and three miles of riding roads have been formed, besides 11 miles of walks. The cost of the land was about \$5,000,000, and up to January, 1873, nearly \$4,000,000 had been expended in its improvement. In 1872 there were about 6,000,000 visitors to the park. The increase in the value of real estate in its vicinity since the beginning of the enterprise is estimated at \$33,000,000. In connection with the park a series of boulevards 200 ft. wide have been designed, leading to it from distant points. The Ocean parkway, one of the finest, is laid out from the S. W. corner of the park to the seashore at Coney island, a distance of 3 m. The Eastern parkway, also laid out, extends from the plaza along the line of Sackett street $2\frac{1}{2}$ m. to East New York. It is a part of the scheme to extend this boulevard so as to cross the East river by the bridge to be constructed at Blackwell's island, and connect with the Central Park boulevard. Others are designed to connect the park with Fort Hamilton and Bath, and with Sheepshead bay, all attractive summer resorts. With the completion of these improvements it is asserted that Brooklyn will be the most attractive city in the United States for driving. Washington park (Fort Greene) is on an elevated plateau E. of the city hall, between Myrtle and De Kalb avenues and Canton and Cumberland streets; it contains 30 acres. During the war of the revolution it was the site of extensive earthworks. It commands an extensive view, and has been recently greatly improved and surrounded by a handsome stone wall. Besides these two there are Tompkins square, containing 8 acres, bounded by Marcy, Greene, Tompkins, and Lafayette avenues; the City park, 7 acres, near the navy yard; Carroll park, 2 acres, bounded by Court, President, Smith, and Carroll streets; and the City Hall park, containing about $1\frac{1}{4}$ acre. The parks are under the control of a board of 10 commissioners, of which the mayor is a member *ex officio*.—Greenwood cemetery, widely noted for its natural and artificial beauties, is on Gowanus heights in the S. part of the city. It was opened for interments in 1842, and contains 418 acres, about one half of which is covered with wood of natural growth. The entire cost of the land was \$281,684. At the main entrance, near 5th avenue and 23d street, is a highly ornamental structure of brown stone, monumental in form, in the middle pointed English Gothic style, 132 ft. long and 40 ft. deep, the central pinnacle being 106 ft. high. It is ornamented with figures representing scenes from the Gospels, chief of which are the entombment and the resurrection of the Saviour. The grounds have a varied surface of

hill, valley, and plain, and are traversed by 17 m. of carriage roads and 15 m. of foot paths. The elevations afford extensive views. Greenwood contains many beautiful monuments, chief among which are the pilots' and firemen's monuments, the soldiers' monument (unfinished), erected by the city of New York, and that

the foot of Greenpoint avenue, the one to the foot of 10th, the other to the foot of 23d street, New York. The Houston street associates run a ferry from the foot of Grand street, Eastern District, to the foot of Houston street, New York. The New York and Brooklyn company runs lines from the foot of Bridge street, Brook-

lyn, to James slip, New York; from the foot of Broadway (formerly S. 7th street), Eastern District, to Grand and to Roosevelt streets, New York; and from the foot of Grand street, Eastern District, to Grand street, New York. The Union ferry company has a capital of \$1,000,000, and owns the following ferries: Catharine ferry, from Main street, Brooklyn, to Catharine street, New York; Fulton ferry, from Fulton street, Brooklyn, to Fulton street, New York; Wall street ferry, from Montague street, Brooklyn, to Wall street, New York; South ferry, from Atlantic street, Brooklyn, to Whitehall street, New York; and Hamilton ferry, from Hamilton avenue, Brooklyn, to Whitehall street, New York. The boats of these ferries run constantly during the day at intervals of a few minutes,

Entrance to Greenwood Cemetery.

to the memory of Miss Canda. In 1871 the total number of interments had been 154,803. The Cypress Hills cemetery, about a mile east of the city limits, beyond East New York, occupies an elevated ridge of land, and contains nearly 400 acres, about one half of which is improved. The cemetery is beautifully arranged, and affords fine views of the surrounding country. More than 70,000 persons have been interred here. In the soldiers' plot are buried the bodies of 4,000 soldiers. The cemetery of the Evergreens, incorporated in 1849, near Bushwick, contains 207 acres, of which 60 are within the city limits. The Citizens' Union cemetery, between Butler and Sackett streets and Rochester and Ralph avenues, contains 10 acres, and is designed as a burial place for colored persons. The cemetery of the Holy Cross at Flatbush contains 36 acres, and is the principal Roman Catholic burying ground. Other cemeteries in the vicinity are Calvary (Catholic), on Laurel Hill, Queens county; Mount Olivet, near Maspeth; Washington, 1½ m. S. of Greenwood; the Friends' cemetery, near the city line, S. of Greenwood; and the Lutheran, between Cypress Hills and Mount Olivet. Nearly all the interments from New York are made in these cemeteries in and around Brooklyn.—Brooklyn is connected with New York by 12 steam ferries, belonging to five companies. The Greenpoint company runs two lines from

New York; and Hamilton ferry, from Hamilton avenue, Brooklyn, to Whitehall street, New York. The boats of these ferries run constantly during the day at intervals of a few minutes,

Fulton Ferry in 1791.

and some of them all night. There are commodious ferry houses for the accommodation of passengers, of which the most noticeable for its size and architecture is that recently

constructed at the foot of Fulton street, Brooklyn. The number of persons who crossed the East river on ferries was 32,845,950 in 1860, 41,350,000 in 1865, and about 60,000,000 in 1872. The inadequacy of the ferries to accommodate the immense number of persons daily crossing between the two cities, and the occasional interruptions through fog and ice, led to the project of the East river bridge, which is now (1873) in process of construction, and is expected to be completed before the end of 1877. The Brooklyn terminus will be in the square bounded by Fulton, Prospect, Sands, and Washington streets; the New York terminus in Chatham street, opposite the City Hall park. The supporting tower on the Brooklyn side is just N. of the Fulton ferry house; the New York tower is at pier 29, near the foot of Roosevelt street. The bridge may be divided into five parts: the central span across the river from tower to tower, 1,595 ft. long; a span on each side from the tower to the anchorage, 940 ft. long; and the approaches from the terminus to the anchorage on each side. The whole length of the bridge will be 6,000 ft. It will be 85 ft. wide, including a promenade of 13 ft., two railroad tracks, and four wagon or horse-car tracks. From high-water mark to the floor of the bridge in the centre will be a distance of 135 ft., so that navigation will not be impeded. The central span will be suspended to four cables of steel wire, each 16 inches in diameter, which are to be assisted by stays. These cables will have a deflection of 128 ft. Each tower rests immediately upon a caisson (see CAISSON) sunk to the rock beneath the river, which on the Brooklyn side is 45 ft. and on the New York side from 82 to 92 ft. below the surface of the water. The Brooklyn caisson is 168 ft. long by 102 ft. wide. The towers erected upon these foundations will be 134 ft. in length by 56 ft. in width at the water line; below the upper cornice at the top these dimensions are reduced, by sloped offsets at intervals, to 120 ft. by 40. The total height above high water of each tower will be 268 ft. At the anchorages each of the four cables, after passing over the towers, enters the anchor walls at an elevation of nearly 80 ft. above high water, and passes through the masonry a distance of 20 ft., at which point a connection is formed with the anchor chains. Each anchorage will contain about 35,000 cubic yards of masonry; that on the Brooklyn side will be in James street. The spans from the anchorages to the towers will be suspended to the cables and carried over the roofs of the buildings underneath. The approach on the Brooklyn side from the terminus to the anchorage will measure 836 ft.; on the New York side, 1,336 ft. These approaches will be supported by iron girders and trusses, which will rest at short intervals upon small piers of masonry, or iron columns built within the blocks crossed and occupied. The streets will be crossed by iron girders at

such elevations as to leave them unobstructed. The Brooklyn terminus is 68 ft. above high tide. The total cost of the bridge, including the property on each side, will probably reach \$10,000,000. — Brooklyn has communication with other parts of Long Island by means of three steam railroads: the Long Island and the Flushing and North Side, which start from Hunter's Point just outside the city limits; and the South Side, the city terminus of which is at the foot of S. 8th street, between which point and Bushwick its cars are drawn by dummies. The Brooklyn, Bath, and Coney island railroad communicates with Coney island, the depot being at Greenwood. A railroad to connect with the new town on Hempstead plains projected by Mr. A. T. Stewart is in process of construction. About 25 lines of city passenger railroads, using horse power, radiate from the ferries to all parts of the city and suburbs. Of these, nine or ten belonging to the Brooklyn city railroad company have their terminus at Fulton ferry; and six other lines start from the same point. Measures are now (1873) in progress for the construction of an underground steam railroad between Fulton ferry and the southern limit of Prospect park. — Brooklyn is not a port of entry, being a part of the customs district of New York; but the immense commercial interests along the shore line form one of the chief features of the city. Its water front of $8\frac{1}{4}$ m. is completely occupied by piers, slips, warehouses, boat and ship yards, ferries, &c. Here are some of the most extensive and commodious docks, piers, and warehouses in the United States. The immense quantities of grain received here make Brooklyn one of the greatest grain depots in the world. Grain is brought from the western states by canal and river to this port, where it is stored for distribution in the eastern and southern ports of the United States and in Europe. The capacity of the grain warehouses is estimated at 12,000,000 bushels. The most extensive commercial interests along the shore line are found between Red Hook point on the south and Main street on the north. Within these limits it is estimated that 25,000 vessels, exclusive of canal boats and lighters, are annually unloaded. The chief articles are molasses, sugar, grain, coffee, oil, hides, and wool. The value of the merchandise annually stored is estimated as follows:

South of Hamilton ferry.....	\$50,000,000
Between Hamilton and South ferries.....	60,000,000
Between South and Fulton ferries.....	126,000,000
Between Fulton ferry and Main street.....	25,000,000
Total.....	\$261,000,000

Fronting Governor's island, near the S. extremity of the shore line, stands the massive Atlantic dock, built by a company incorporated in 1840 with a capital of \$1,000,000. The basin is a parallelogram in form, has an area of 40 acres with a depth of 25 ft., and will accommodate the largest vessels; 500 vessels can

Atlantic Dock.

occupy it at the same time, and 400 canal boats besides many other vessels have floated upon it at once. The pier line on Buttermilk channel is 3,000 ft. long; the total wharfage is about 2 m. Surrounding the basin on all sides, excepting an entrance 200 ft. wide for vessels, are substantial brick and granite warehouses, from two to five stories high, and covering an area of 20 acres. Grain is the chief article stored here, for the reception of which nine steam elevators are employed, the largest of which will raise 3,000 bushels per hour. The value of merchandise stored annually in the warehouses of this company and those south of them to Red Hook point is estimated as follows:

Grain	\$20,000,000
Sugar and molasses	15,000,000
Provisions	2,200,000
Flour	1,500,000
Lumber and stone	1,200,000
Cotton	1,500,000
Guano	1,500,000
Rags	500,000
Saltpetre and brimstone	100,000
Salt	500,000
Iron	2,000,000
Miscellaneous, including rosin, turpentine, &c.	4,000,000
Total	\$50,000,000

South of the Atlantic dock, on Gowanus bay, are the extensive Erie and Brooklyn basins, not yet completed. The property of this company comprises an extensive water front with 28 ft. of water in the channel. These basins are separated by a pier, of which Columbia street forms the E. side. On the W. side of this pier is the Erie basin, containing about 60 acres of water and surrounded by spacious piers with extensive warehouses. E. of the Columbia street pier is the Brooklyn basin, 1,300 ft. long and 450 ft. wide, with an area of 40 acres. Near the Erie basin two extensive dry docks have been recently constructed, capable of receiving vessels of large size even when loaded. At the N. end of Washington avenue is the Wallabout basin, recently formed from marsh land, with extensive piers

and bulkheads. The basin proper extends from Washington avenue S. to Hewes street, 1,500 ft. Lumber, coal, and brick yards line the entire length of the basin on one side. The number of vessels that discharged cargoes at these docks in 1872 exceeded 3,000. The cost of the Wallabout improvement has been about \$1,000,000. By it an additional wharfage of three fourths of a mile is secured; while the distance between the Eastern and Western Districts has been reduced three fifths of a mile by the extension of Washington avenue through the marsh from Flushing to Kent avenue. Between the navy yard and Bushwick creek, in Williamsburgh, the shore is lined with ship yards, distilleries, sugar refineries, lumber, brick, and coal yards, and gas works; while the Greenpoint water front, between Bushwick and Newtown creeks, is chiefly occupied by large ship yards. The United States navy yard, on the S. shore of Wallabout bay, embraces a total area of 144 acres, including more than a mile of the most eligible wharfage in the harbor. The yard proper comprises 45 acres, enclosed by a high brick wall. About 2,000 men are constantly employed here.

Within is an immense dry dock, one of the most remarkable structures of the kind in the world, built of granite, at a total cost of \$2,113,173. The main chamber is 286 ft. long by 35 ft. wide at the bottom, and 307 ft. long by 98 ft. wide at the top, with a depth of 36 ft. The dock can be emptied by steam pumps in 4½ hours. Half a mile E. of the navy yard, on the opposite side of the Wallabout, is the marine hospital, a handsome structure with 21 acres of ground, and with accommodations for 500 patients. The United States naval lyceum, founded by officers of the navy in 1833, is situated in the navy yard; it has a library, a large collection of curiosities, and valuable geological and mineralogical cabinets. Fronting Flushing avenue, a short distance E. of the navy yard, are extensive marine barracks.—Brooklyn contains numerous manufacturing

establishments remarkable for the extent of their operations. In Kent avenue, in the Eastern District, is the printing house and book manufactory of the firm of D. Appleton and co., the most extensive and completely arranged establishment of the kind in the United States. The buildings are constructed of brick with white marble trimmings, and occupy three sides of a square, enclosing one and a quarter acre. Each corner has a tower-like structure, the one on the N. side being 100 ft. high. The establishment contains commodious press, composing, and store rooms, stereotyping and electrotyping departments, and the extensive book-binery. In 1870 the number of manufacturing establishments in Kings county, including minor industries, nearly all within the limits of Brooklyn, was 1,043; capital invested, \$25,287,981; number of hands employed, 18,545; value of products, \$60,848,673. The most extensive interests were:

ESTABLISHMENTS.	No.	Capital.	Value of products.
Coal oil, rectified.....	6	\$883,500	\$1,747,255
Drugs and chemicals.....	15	843,000	1,799,357
Engines and boilers.....	12	321,645	457,000
Flouring mills.....	5	645,000	2,692,000
Gas.....	4	2,200,000	2,166,384
Glass ware.....	12	460,666	993,464
Hats and caps.....	7	816,000	1,074,948
Iron, all kinds.....	30	968,055	1,538,724
Lined oil.....	1	250,000	1,638,000
Lumber.....	10	563,000	1,364,100
Machinery.....	35	785,100	1,108,998
Malt liquors.....	27	1,481,000	1,489,529
Marble and stone work.....	30	392,900	661,565
Paints.....	8	618,000	1,206,850
Sash, doors, and blinds.....	26	296,800	653,397
Ship building and repairing.....	12	127,800	218,007
Sugar (refined) and molasses.....	7	3,090,000	16,706,551
Tin, copper, and sheet-iron ware.....	33	762,100	1,213,495
Tobacco (not cigars) and snuff.....	5	755,000	4,036,912
Woollen goods.....	2	512,000	1,280,000

Among other extensive manufacturing establishments are the Brooklyn brass and copper company, the New York agricultural works, the American steel company's works, Campbell's printing press manufactory, and the Bushwick chemical works. The numerous buildings of the last named are built of brick and cover an area of six acres. In the Eastern District are extensive sugar refineries and distilleries, and numerous lagerbier breweries of immense size.—Brooklyn contains 11 insurance companies chartered by the state of New York, with assets aggregating \$3,748,557. There are 5 national banks, with an aggregate capital of \$1,552,000, and 6 state banks acting under special charters, with a capital of \$1,600,000. In 1872 there were 17 savings banks, with 115,693 depositors and deposits amounting to \$39,458,630. The principal of these were the Brooklyn savings bank, which had 24,293 depositors and deposits to the amount of \$10,375,872, and the Dime savings bank, with 26,458 depositors and \$6,695,503 deposits. There are also two safe deposit companies and a trust company.—The city is divided into 25 wards, and is governed by a

mayor (salary \$10,000) and a board of 36 aldermen (\$1,000), elected by the people for two years. There are also 13 departments, the heads of which are in most cases appointed by the mayor with the consent of the aldermen for two years, viz.: finance, audit, treasury, collection, arrears, law, assessment, police and excise, health, fire and buildings, city works, parks, and public instruction. Besides the United States circuit and district courts for the eastern district of New York, the supreme court of the state for the second judicial district, and the county court of Kings county, which hold sessions here, there are the city court of Brooklyn, consisting of three judges, a police court, and six courts of justices of the peace. Brooklyn with the rest of Kings county elects three members of congress, and two senators and nine assemblymen in the state legislature. For police purposes the city is divided into 10 precincts and 8 sub-precincts. The department of police is under the control of a board of commissioners, consisting of a president and two other members. The force consists of a superintendent, an inspector, 10 captains, 51 sergeants, 25 roundsmen, 389 patrolmen, and 30 doormen, constituting the ordinary force, besides a superintendent of telegraphs with 8 operators, a detective force of 8 under command of a sergeant, 4 boiler inspectors, a drill captain, and a fire marshal. The pay of the superintendent is \$4,000 a year, of the inspector \$3,000, of the captains \$2,000 each, of the sergeants \$1,500, and of the patrolmen \$1,100. According to the latest report of the police department, the whole number of persons arrested during the 8 months ending Dec. 31, 1872, was 15,906, of whom 10,124 were foreign and 5,782 native born. The principal offences were: drunkenness, 6,421; assault, 3,204; disorderly conduct, 1,142; violation of city ordinance, 1,005; petit larceny, 718; grand larceny, 247; felonious assault, 242; burglary, 84; robbery, 22; murder, 14. Lost children recovered, 1,112; value of property recovered, \$77,816, of which \$75,805 was restored to owners. The fire department is under the control of a board, consisting of a president and two commissioners. The force consists of a chief and an assistant engineer, 6 district engineers, 16 steam fire engines, and 5 hook and ladder trucks, with a total of 189 men. The pay of the chief engineer is \$3,000 a year, of the assistant engineer \$2,000, and of the district engineers \$1,500 each; the other members of the force are paid from \$800 to \$1,000 a year each. There are 90 points in the city whence alarms may be transmitted by telegraph.—The city is supplied with water from a chain of ponds extending from Jamaica E. to Hempstead plains, whence it is brought in a brick-covered conduit to Ridgewood reservoir, into which it is forced by three powerful engines. The furthest of these ponds is 19 m. distant from the city hall. The Ridgewood reservoir is 170 ft. above the East river.

and has a capacity for about 160,000,000 gallons. Besides this, Mount Prospect reservoir has a capacity for 20,000,000 gallons, with an elevation of 28 ft. above that of Ridgewood. From these two reservoirs the water is distributed throughout the city. There are 277 m. of distribution pipes and 2,000 hydrants. The average daily consumption of water in 1872 was 24,000,000 gallons. To secure a supply of water in case of drought a storage reservoir at Hempstead is in process of construction; its estimated cost is \$1,393,743, and its capacity will be about 1,055,000,000 gallons. The bonds issued by the city on account of the water works amounted in 1873 to \$9,521,000; this department is self-sustaining. The water works are under the control of a board of city works, comprising three commissioners and a secretary, a chief engineer, water purveyor, register of water rates, and a general superintendent of sewers. This department also has charge of the sewerage and cleaning, paving, and repairing the streets of the city. In 1872 there were 546 m. of streets in the city, of which 283 m. were paved; the total length of sewers was 214 m. The 2d division of the national guard of the state of New York, consisting of the 5th and 11th brigades, has its headquarters here, and is composed mainly of citizens of Brooklyn. This force consists of 3 batteries of artillery, 8 troops of cavalry, and the 13th, 14th, 23d, 28th, 32d, and 47th regiments of infantry.—The city debt, Jan. 1, 1873, was \$32,012,884, and consisted of \$20,260,929 in bonds issued for public, and \$9,458,055 for local improvements, and certificates amounting to \$2,293,900. The city's quota of the county debt was \$3,471,977. Of the bonds issued for public improvements, the most important are \$8,738,000 public park loan, \$9,521,000 permanent water loan, \$2,100,000 East river bridge loan, \$726,000 Wallabout bay improvement loan, and \$345,000 Kent avenue basin loan. The property in possession of the city was valued at \$26,220,000. The amounts authorized to be expended during the year 1872 for city purposes were: principal of public debt, \$131,650; interest on same, \$877,600; principal of certificates, \$178,417; interest on same, \$9,748; salaries of city officers, \$245,000; board of health, \$25,000; general purposes, \$795,596; board of education, \$651,700; police department, \$518,640; fire department, \$332,417; water and sewerage department, \$190,000; park commission, \$75,000; resurveys, ward maps, &c., \$30,000; repairs to wells, pumps, &c., \$8,000; total for city purposes, \$4,058,768, of which \$3,375,062 was to be raised by taxation. The amount authorized for county purposes was: for quota of state tax, \$1,103,495; commissioners of charities, \$400,000; maintenance of parade ground, \$2,000; supervisors' budget, \$870,700; total for county purposes, \$2,376,195. The following table exhibits the valuation of property and taxation since the consolidation:

YEARS.	PROPERTY.		Tax.
	Real.	Personal.	
1855.....	\$84,574,348	\$10,216,867	\$1,582,692
1856.....	85,795,741	10,063,994	1,381,114
1857.....	87,848,725	11,168,868	1,788,884
1858.....	88,186,781	10,776,176	1,567,948
1859.....	90,082,122	10,970,518	1,256,820
1860.....	92,198,422	11,068,521	1,969,693
1861.....	98,562,519	11,490,374	2,485,929
1862.....	94,198,752	10,981,799	1,983,898
1863.....	99,674,808	12,568,920	1,784,759
1864.....	103,729,497	15,798,688	8,810,081
1865.....	106,484,358	16,944,475	3,786,985
1866.....	118,928,421	22,458,415	4,662,854
1867.....	122,982,254	20,262,581	5,421,323
1868.....	131,260,861	17,638,067	5,676,676
1869.....	179,118,331	17,564,990	6,510,166
1870.....	182,783,766	17,543,770	8,199,575
1871.....	187,651,591	18,245,581	8,728,894

—Prominent among the charitable institutions is the city hospital in Raymond street. Accommodations are afforded to those unable to pay, while private wards may be obtained at a moderate price. The Long Island College hospital occupies 14 lots at the junction of Pacific and Henry streets. Its plan embraces a hospital with an indoor and an outdoor department for the treatment of medical and surgical diseases; a lying-in department; a department for the regular education and licensing of nurses; and a college in which all the branches of medical science are taught. In 1870 it had 9 professors, 72 students, and 315 alumni. There are also St. Mary's female hospital in Clinton street, and St. Peter's hospital under the care of the Sisters of Charity; the eye and ear hospital, in Washington street, established in 1868; the dental infirmary, in Washington street, organized in 1870 to afford gratuitous dental treatment to the indigent; and six dispensaries. The female orphan asylum, corner of Clinton and Congress streets, had in 1871 530 girls under charge of 16 Sisters of Charity. Besides the Brooklyn orphan asylum in Cumberland street, which has accommodations for more than 150 children, and the Roman Catholic asylum recently erected in Albany avenue, with still greater accommodations, there are three other orphan asylums, one of which is for colored children. The Graham institution, corner of Washington and De Kalb avenues, for the relief of aged and indigent females, was founded in 1851 through the beneficence of John B. Graham, and has accommodations for 90 persons. The industrial school association and home for destitute children, organized in 1854, has a commodious building and 14 lots in Butler street, between Flatbush and Vanderbilt avenues; its mission is to reach children not attending other schools, and afford them instruction, and a home and clothing to the needy. The church charity foundation occupies a handsome building with 43 lots on the corner of Albany avenue and Herkimer street; its object is to afford a foundation upon which may be built up the different charities connected with the Episcopal church. The society for improving the condition of the poor is one of

the oldest benevolent societies in the city, and is designed to aid the poor by procuring them employment and temporary relief. There are numerous other charitable institutions, among which is the children's aid society, which opened a newsboys' home in 1866 and a children's home in 1867, affording to neglected boys in the streets industrial training and places to sleep. The society embraces a special relief department for placing boys and girls in good homes; a sewing machine or girls' industrial department; and an industrial department and school for boys. The truant home, on the Jamaica turnpike, has an average number of 100. Excellent accommodations are also afforded by the charitable institutions of Kings county, which embrace the almshouse, hospital, nursery, lunatic asylum, &c., in Flatbush.—The common schools are classified as grammar and primary, there being no public high schools. They are under the control of a board of education of 45 members, and a city superintendent with an assistant. Under their supervision in 1872 there were 52 schools, of which 13 were primary and 5 were for colored children, besides the Protestant orphan asylum school, the church charity foundation school, the Catholic orphan asylum school for boys, the Catholic orphan asylum school for girls, and the Howard colored orphan asylum school. There are 52 school houses, of which 36 are built of brick and 16 of wood. For the school year ending Jan. 31, 1872, the number of teachers was 857, of whom 823 were females. The whole number of pupils enrolled during the year was 102,033, embracing 66,890 different pupils. Of this number 1,670 were colored. The average number registered was 40,935; average attendance, 36,044. These statistics are exclusive of the evening schools and orphan asylums. Seven evening schools for white and two for colored children were open during the 12 weeks beginning with October, employing 26 male and 82 female teachers. The whole number of pupils, including 191 colored, was 6,001, of whom 4,429 were males and 1,572 females; average attendance, 2,198. The whole number of the preceding year was 5,416, with an average attendance of 2,071. The cost of maintaining these schools was \$13,164. In the orphan asylums 14 teachers were employed, the whole number of pupils being 1,049, with an average attendance of 818. The sum of \$11,391 was apportioned from the public school fund to these schools. The amount expended in the day schools for teachers' wages during the year was \$468,841, and \$8,095 for music teachers. The total amount expended for school purposes was \$719,800. There are about 35,000 volumes in the school libraries, valued at \$43,750. In addition to the public schools there are many excellent private seminaries. The Packer collegiate institute, which ranks among the first seminaries for females in the United States, was incorporated in 1853, and named after the late William S. Packer, by

whose widow the institution was liberally endowed. Its large Gothic structure in Joralemon street, with its grounds and boarding establishment, valued at over \$800,000, is insufficient for its wants. In 1872 it had 38 professors and teachers, besides special lecturers, between 700 and 800 students, and a library of more than 4,000 volumes. There are free and endowed scholarships for between 30 and 40 pupils. The collegiate and polytechnic institute for boys, in Livingston near Court street, founded in 1854, with a capital stock subsequently increased to \$100,000, is under the control of a board of 17 trustees. In 1872 it had 27 instructors, 597 students, and a library of 3,000 volumes. The juvenile high school, opposite the preceding, designed for the thorough instruction of boys under 12 years of age in the rudiments of an English education, has an average attendance of about 300. The Adelphi academy, founded in 1863, and incorporated as an endowed institution in 1869, has a fine building in Lafayette avenue, corner of St. James place, and receives pupils of both sexes to all grades except the collegiate. In 1873 it had 31 instructors and 552 pupils. Among others of importance are the Brooklyn Heights seminary, in Montague street, for the education of young ladies, and the college of St. John the Baptist (Roman Catholic), corner of Lewis street and Willoughby avenue. There are also three convents and a monastery. —The chief library is the mercantile, founded in 1857, which contains about 41,000 volumes, and is provided with a spacious reading room. The annual subscription for each member is \$5. The Brooklyn institute and youths' free library, liberally endowed by Augustus Graham, occupies a commodious building in Washington street, containing library, reading and lecture rooms, a public hall, and a picture gallery; it has about 12,000 volumes. The Long Island historical society, organized in 1863, has a library of nearly 20,000 volumes and an equal number of pamphlets, besides valuable treasures of art and history. The Brooklyn library association of the Eastern District had in 1870 over 8,000 volumes, and the law library in the court house is rich in that department of literature. The chief art institutions are the Brooklyn art association and the academy of design.—The chief places of amusement are the academy of music, in Montague street; the Brooklyn theatre, corner of Washington and Johnson streets; the Park theatre, in Fulton street, opposite the City Hall park; and the Olympic, which is devoted to varieties, and Hooley's opera house, to minstrelsy. The philharmonic society gives a series of classical instrumental concerts annually. There are four clubs: the Brooklyn social, which meets at the corner of Pierrepont and Clinton streets; the Long Island, political and social, corner of Clinton and Renssen streets; the Faust, established in 1871 chiefly for journalists, artists, actors, &c.; and the yacht club.—The young men's Christian association

of Brooklyn, organized in 1854 with 207 members, is in the front rank of similar institutions in the United States. In 1872 it occupied the elegant new building on the corner of Fulton street and Gallatin place, which is rented by the association, and is admirably adapted to the social enjoyment and instruction of the members. It is of architectural iron, four stories high; its dimensions are 100 by 75 ft. The first floor above the ground embraces the library, reading, prayer-meeting, and conversation rooms, a large, handsomely furnished parlor, and offices. The second and third floors are devoted to a hall for lectures, concerts, &c., with seats for 1,200 persons; also various class, music, and debating rooms. The library contains about 6,000 volumes, while the reading room is well supplied with newspapers and magazines. Prayer meetings are held every day and evening, daily instruction in all branches is afforded by numerous recitations and lectures, and frequent concerts are given. The number of instructors is 10. Much work is done by committees in distributing clothing and other articles among the needy, visiting the sick, &c. In January, 1873, the number of members was 3,700, and was rapidly increasing. The annual subscription for each member is \$2. There are two other local young men's Christian associations in the city. Three daily papers are published in Brooklyn, 1 semi-weekly in German, 6 weeklies, 1 bi-weekly, 1 semi-monthly, and 4 monthlies. There are 57 masonic lodges, 18 lodges and 3 encampments of odd fellows, 27 divisions of the sons of temperance, and 16 lodges of good templars.—The number of churches is 230, of which 38 are Methodist Episcopal, 86 Episcopal, 29 Baptist, 29 Presbyterian, 28 Roman Catholic, 18 Congregational, 15 Reformed, 11 Lutheran, 6 Methodist non-episcopal, 4 Jewish, 4 Universalist, 3 Unitarian, 2 Friends', 1 New Jerusalem, and 6 of other denominations. In 1870 the total number of church organizations of all denominations in Kings county was 276; edifices, 262; sittings, 197,125; value of property, \$12,025,000.—Brooklyn was settled by emigrants from Holland who had been sent out by the Dutch West India company to colonize New Netherland. The first settlement, according to Stiles ("History of the City of Brooklyn," 3 vols., 1867-'70), was made by William Adriaense Bennett and Jacques Benty, who purchased in 1636 from the Indians a tract of 930 acres of land at Gowanus, upon which a dwelling house was soon erected. In the following year John Jansen de Rapalje, one of the Walloon emigrants who settled at New Amsterdam in 1623, purchased a tract of land where the navy yard now is, which, however, he did not occupy as a residence till 1654. In the mean time others, many of whom were Walloons, settled in this locality, which became known as the Waal-bogt, afterward corrupted to Wallabout. In 1646 nearly the whole water front from Newtown creek to the S. side of Gowanus bay was held by individ-

uals who were engaged in its cultivation. Settlers under patents from the Dutch West India company had established themselves between Flatbush and the "Ferry," along what is now Fulton street, S. E. of the present city hall, and the settlement thus formed was called Breuckelen, after the village of that name near Amsterdam in Holland. In 1646 the town was organized by Gov. Kieft, who appointed Jan Everesen Bout and Huyck Aertsen as schepens, or superintendents, to preserve the peace and regulate the police of the community. In 1667 Gov. Richard Nicolls granted a full and ample patent to certain inhabitants of Breuckelen, their heirs, successors, and assigns, of all land acquired, or to be purchased or acquired, on behalf of the town, from the Indians or others. This patent was confirmed by Gov. Dongan in 1686, in consideration of an annual quitrent of 20 bushels of good merchantable wheat. This quitrent, or its equivalent, continued to be paid by the town as late as 1786. Brooklyn was the scene of several memorable events during the revolution. On Aug. 27, 1776, the battle of Long Island was fought. (See LONG ISLAND.) From this time until November, 1783, Brooklyn was occupied by the English. In 1776, and for six years thereafter, until New York was evacuated, several condemned hulks were moored in the Wallabout, and used for the detention of American seamen captured by the British. It is estimated that 11,500 Americans died on these plague ships. The shores of the Wallabout were full of dead men's bones, and for many years the tides washed out the remains from the sand. After some years of agitation, the bones were finally collected in 1808, and laid in a vault near the navy yard, with imposing ceremonies. In 1873 they were transferred to a vault constructed for the purpose in Washington park, where it is also proposed to erect a monument to the memory of the martyrs. For many years after the settlement of Brooklyn, its inhabitants worshipped in New Amsterdam. In 1655 a church was erected in the neighboring town of Midwout, or Flatbush, for the accommodation also of Brooklyn and Amersfoort. The Rev. Mr. Polhemus was the pastor of this church. In 1660 the Rev. Henry Selwyn (otherwise Henricus Selyns), of Holland, was installed as pastor of the congregation in Brooklyn. The first church edifice in Brooklyn was erected in 1666, in the middle of the highway, now Fulton street, near Lawrence. Its successor is the first Reformed church in Joralemon street, erected in 1835. The Episcopal church of Brooklyn was incorporated by act of the legislature in 1787. In 1795 the church was reorganized and incorporated under the name of St. Ann's church. The first Methodist church was incorporated in 1794; the first Presbyterian, Baptist, and Roman Catholic churches in 1822; and the first Congregational church in 1839. The earliest ferry between Long Island and New Amsterdam was, according to Stiles, established as early as 1642, and

connected the present Fulton street, Brooklyn, with what is now Peck slip, New York; these points were for more than a century the principal ferry landings. The first steam ferry boat was the Nassau, which began running in 1814. Brooklyn was incorporated as a village in 1816, and became a chartered city in 1834. On Sept. 9, 1848, occurred the largest fire in its history, consuming seven blocks in Fulton and adjoining streets, between Poplar and Concord streets. On Jan. 1, 1855, it was consolidated with the city of Williamsburgh and the town of Bushwick (including the village of Greenpoint) under the common name of Brooklyn; what had formerly been called Brooklyn being designated as the Western District, and the other portion as the Eastern District. Williamsburgh was founded by Richard W. Woodhull, who at the beginning of this century settled near Bushwick street (now North Second). It was incorporated as a village in 1827, and as a city in 1851. In 1855 its population was 48,367. The streets of Brooklyn were first lighted by gas in 1848, and water was introduced in 1855. There was a volunteer fire department from 1786 to 1869, when the paid department was organized. A commission is now (September, 1873) engaged in arranging the terms of annexation of the rest of Kings co. to Brooklyn. (See KINGS.)

BROOKS, a S. county of Georgia, on the Florida border, bounded S. E. by the Withlacoochee river, and watered by its tributaries and the Ocilla river; area, 550 sq. m.; pop. in 1870, 8,342, of whom 4,231 were colored. The Atlantic and Gulf railroad passes through it. The chief productions in 1870 were 171,190 bushels of Indian corn, 45,716 of oats, 24,574 of peas and beans, 32,445 of sweet potatoes, and 3,466 bales of cotton. There were 491 horses, 2,618 milch cows, 5,578 other cattle, 4,924 sheep, and 11,087 swine. Capital, Quitman.

BROOKS, Charles Shirley, an English author, born at Brill, Oxfordshire, about 1815. He studied law, but devoted himself to literature. Two of his plays, "Our New Governor" and "The Creole," were quite successful. He became a parliamentary reporter on the "Morning Chronicle," and was sent to Turkey, Egypt, and southern Russia to investigate the condition of the laboring classes. His letters from Russia have been issued in book form. In 1855 he published "Aspen Court," which has been followed by the other successful novels, "The Gordian Knot," "The Silver Cord," and "Sooner or Later." He is a keen satirist in prose and verse, and on the death of Mark Lemon, in 1870, he became editor of "Punch," to which he had been an early and frequent contributor, as well as to the "Illustrated London News."

BROOKS, Charles Timothy, an American author, born in Salem, Mass., June 20, 1813. He graduated at Harvard college in 1832, and in 1837 was settled as a Unitarian clergyman in Newport, R. I., where he has ever since resided. He published there in 1851 a pamphlet entitled "The Controversy touching the Old

Stone Mill." He is an accomplished scholar, and especially devoted to German literature. He has published a translation of Schiller's "William Tell;" a volume of miscellaneous poems from the German, in the series of "Specimens of Foreign Standard Literature;" a translation of Schiller's "Homage to the Arts," &c.; "German Lyrics;" "Songs of the Field and Flood;" a translation of Goethe's "Faust;" translations of Richter's "Titan" and "Hesperus;" and translations from Schefer, Kortum, and Busch.

BROOKS, I. James, an American journalist and politician, born in Portland, Me., Nov. 10, 1810, died in Washington, D. C., April 30, 1873. At the age of 11, having lost his father, he was placed in a store, at 16 became a school teacher, and in 1831 graduated at Waterville college, at the head of his class. He was next principal of the Latin school in Portland, then travelled through the southern states and among the Creek and Cherokee Indians, wrote letters to various journals, became the correspondent at Washington of several papers, and was the originator of the system of regular Washington correspondence. Becoming in 1835 a member of the legislature of Maine, he introduced the first proposition for a survey for a railroad from Portland to Montreal and Quebec. The same year he visited Europe, travelling on foot over a great part of the continent and the British islands, and gave an account of his adventures in a series of letters to the "Portland Advertiser." On his return in 1836 he established the New York "Express," of which for many years both a morning and evening edition were published, but which is now exclusively an evening journal. In 1847 he was elected as a whig to the assembly of the state of New York, and in the following year chosen a member of congress from New York city, in which post he was continued by reelection till 1853. In congress he took part in favor of the passage of the compromise of 1850, and there and in his newspaper advocated the principles of the American party. Soon after the outbreak of the civil war he joined the democratic party, by whom in 1864 he was again returned to congress from the city of New York, and remained a member till his death, having received four successive reelections. In 1871 he made a rapid tour of the globe, of which he gave an account in a volume entitled "A Seven Months' Run up and down and around the World" (New York, 1872). **II. Erastus**, an American journalist, brother of the preceding, born in Portland, Me., Jan. 31, 1815. He was sent to Boston at the age of eight, where he was employed in a grocery store, and obtained the rudiments of learning at an evening school. He subsequently became a printer, and published a newspaper called "The Yankee" at Wiscasset, Me. Afterward, having graduated at Brown university, he became the principal of a grammar school at Haverhill, Mass., and editor of the "Haverhill Gazette." In 1836 he was en-

gaged as Washington correspondent of the New York "Daily Advertiser" and of several New England journals, and soon afterward became with his brother joint editor and proprietor of the New York "Express," which position he still retains (1873). In 1843 he traveled extensively in Europe, and in 1853 and 1855 he was elected to the New York state senate. While in the senate he advocated a bill divesting the Roman Catholic bishops of the title to church property in real estate, and became in consequence involved in a controversy with Archbishop Hughes, which was published in a volume ("Controversy on Church Property," New York, 1855). In 1856 he was nominated for governor of New York by the American party, but was not elected. He subsequently joined the democratic party. In 1872 he was appointed member of a commission to revise the state constitution.

BROOKS, James Gordon, an American poet, born at Claverack, N. Y., Sept. 3, 1801, died in Albany, Feb. 20, 1841. He graduated at Union college in 1819, studied law, and removed in 1823 to New York, where he became editor of the "Minerva," a literary journal, and afterward of the "Literary Gazette," the "Athenæum," and the "Morning Courier," continuing in all these papers the publication of his verses. In 1828 he married Mary Elizabeth Aikin of Poughkeepsie, and the next year appeared "The Rivals of Este and other Poems, by James G. and Mary E. Brooks." The year after they removed to Winchester, Va., and in 1838 to Rochester, N. Y., and afterward to Albany. Mary E. Brooks, his wife, in addition to her literary abilities, was a skilful designer. The original drawings for the plates in the "Natural History of the State of New York," edited by her brother-in-law Mr. James Hall, were made by her from nature.

BROOKS, John, M. D., an American officer, born at Medford, Mass., May 31, 1752, died March 1, 1825. Having settled at Reading as a physician, he undertook the drilling of a company of minute men, with whom, on the news of the expedition to Lexington, he marched in time to see the retreat of the British. Promoted soon after to the rank of major in the continental service, he was especially serviceable to the army as a tactician. He was made lieutenant colonel in 1777, and in the battle of Saratoga stormed the intrenchments of the German troops. He was a faithful adherent of Washington during the conspiracy at Newburgh. After the peace he resumed the practice of the medical profession in Medford, and was for many years major general of the militia of his county. In 1816 he was elected governor of Massachusetts, and was reelected annually till 1823, when he declined being again a candidate.

BROOKS, Maria, an American poetess, known also by the name of "Maria del Occidente," which she first received from Robert Southey, born at Medford, Mass., about 1795, died at

Matanzas, Cuba, Nov. 11, 1845. Her family were Welsh, her maiden name being Gowen. Having lost her father while young, she attracted the regard of Mr. Brooks, a Boston merchant, who completed her education at his own expense, and afterward married her. She published nothing till 1820, when "Judith, Esther, and other Poems" appeared. On the death of her husband in 1823 she removed to Cuba, where she came into possession of some property, and where she finished her principal work, "Zophiel, or the Bride of Seven," the first canto of which was published in Boston in 1825. In 1830 she visited Paris and London, still improving her work, which appeared in London in 1833. In 1843 she published "Idomen, or the Vale of Yumuri." Her "Ode to the Departed" was written in 1843.

BROOKS, Peter Chardon, an American merchant, born at Medford, Mass., Jan. 6, 1767, died in Boston, Jan. 1, 1849. His boyhood was passed upon a farm. He afterward went to Boston, and engaged in the business of marine insurance, acquiring an ample fortune, and was for several years president of the New England insurance company. In 1803 he retired from business, and became active in various benevolent enterprises. He was a member of the first municipal council of Boston after its incorporation as a city, and at different times a member of the executive council and of the senate and house of representatives of Massachusetts. In the legislature he took a prominent part in urging the measures for suppressing lotteries.—See "Life of P. C. Brooks," by Edward Everett, in Hunt's "American Merchants."

BROOKS, Phillips, an American clergyman, born in Boston, Dec. 13, 1835. He graduated at Harvard college in 1855, studied theology at the Protestant Episcopal seminary in Alexandria, Va., and from 1859 to 1870 was rector of churches in Philadelphia. In the latter year he became rector of Trinity church, Boston. He is noted as one of the most brilliant pulpit orators of the Episcopal denomination.

BROOKS, Preston S., an American politician, born in Edgefield county, S. C., Aug. 4, 1819, died in Washington, Jan. 27, 1857. He graduated at South Carolina college in 1839, was elected to the legislature in 1844, and in 1846 raised a company for the Mexican war and led it as captain in the Palmetto regiment. He was elected to congress in 1853. Mr. Sumner of Massachusetts, having in a speech in the United States senate used expressions which were considered by the pro-slavery members of congress highly offensive to the South, and South Carolina in particular, was on May 22, 1856, violently assaulted in the senate chamber by Mr. Brooks, and beaten on the head with a cane. A committee of the house of representatives reported in favor of the expulsion of Mr. Brooks; but the report failed to receive the requisite majority of two thirds. He was indicted for assault, pleaded guilty, was sen-

tenced to pay a fine of \$300, and resigned his seat in congress, but was reelected without opposition. He died suddenly from acute inflammation of the throat.

BROOM, a genus of plants, consisting of shrubs or small trees, with leaves in threes and yellow or purplish white flowers, belonging to the natural order *leguminosæ*. The common broom, the *spartium scoparium* of Linnaeus, and the *cytissus scoparius* of Lamarck, is a bushy shrub, with smooth, angular, dark-green branches, and yellow, butterfly-shaped, axillary blossoms, and is common on sandy heaths in Great Britain. Bundles of its twigs make brooms for sweeping. Its roasted seeds are sometimes used as coffee. The fibres of its bark, separated by soaking, may be manufactured into matting and cordage. A decoction of its tops has been celebrated as

Broom (*Spartium scoparium*).

a medicine for dropsy, but, though often efficacious as a diuretic, it is not certain in its operation. The *spartium junceum*, or Spanish broom, is a native of Spain, abundant in Valencia, and is supposed to be the plant which, according to Pliny, overspread whole mountains near New Carthage (Cartagena). Its twigs and bark are manufactured into carpets and various implements, and are articles of merchandise. It is cultivated as an ornamental shrub in gardens.

BROOM CORN (*sorghum vulgare*), a plant which is a native of India, and is cultivated in Europe and America, having a jointed stem like a reed, usually rising to the height of from 6 to 10 ft., bearing an effuse spike, of which brooms are made. It has yellow oval seeds, villous oblong florets, and broad lanceolate leaves. The introduction of broom corn as an agricultural product into this country is attributed to Dr. Franklin. He is said to have accidentally seen an imported whisk of corn in the possession of a lady of Philadelphia, and while examining it as a curiosity saw a seed, which he planted, and from this small beginning has sprung the present product of this article in the United States. The cultivation of the broom corn is now very extensively carried on in most parts of the United States, especially by some branches of the society of Shakers, and the manufacture of it into brooms is an important industry. The seed of the broom corn is excellent for fattening sheep. It is also fed with advantage to horses and poultry, and, when ground with Indian corn, rye, oats, or

barley, to cattle. Ground and mixed with wheat bran, it is good for milch cows. It is considered by some to be worth as much per bushel, when fully ripened and well cured, as Indian corn. It may be dried on barn or garret floors, and the ground is often used for the purpose. Frequent stirring, while drying, is essential. It should be run through a fanning mill before grinding. As to the yield of seed, it is somewhat precarious; yet it will often more than pay the whole expense of cultivation and preparing the crop for market. In some cases 150 bushels of good seed have been obtained from an acre, but this is a rare yield. The harvesting of the crop most generally commences while the seed is in its earliest stage, or milky state, as the early harvested broom is the brightest and best; consequently there must be a sacrifice of more or less seed. Alluvial lands are the best for raising broom corn; yet almost any soil that will raise good maize will produce a tolerable crop of broom. It will pay well for manuring and for careful culture. No crop is more beautiful in appearance than the standing corn, when in perfection. It often attains to a height of 12 or 15 ft. The stalks of the plant are long and hard, and are considered of but little consequence, except for manure. However, cattle having access to them before the frost will feed well upon their leaves.—The planting is generally done with a machine, drawn by a horse, in rows 3 ft. apart, wide enough for the cultivator or plough to pass conveniently. The seed is dropped in hills from 16 to 18 inches apart, four quarts of seed being sufficient to plant an acre. The seed will germinate and the blade make its appearance in four or five days, if the weather is favorable and the soil productive.

Broom Corn (*Sorghum vulgare*).

It may be manured in the hill, or by spreading the manure upon the ground, or in both ways if high cultivation is desired. One man, with

a horse and a machine that will plant two rows at the same time, may plant from 10 to 12 acres in a day. The labor of one hand four months will cultivate about six acres, and harvest the same, and the average produce per acre is about 500 lbs. After the corn is well up, the cultivator can be profitably used three or four times before hoeing, after which commences the weeding and thinning. As a general rule, two hoeings are sufficient. At the last time, and when the corn is 10 or 12 inches high, the Shakers use a double-moulded plough, which turns a furrow each way. Planting may be performed with safety from the middle of May to the 1st of June, and even later if the season is good. The usual practice in harvesting is to bend the stems or stalks of the corn some 2½ or 3 ft. from the ground, and leave them for a few days to dry. They are then cut 6 or 8 inches from the brush, and laid into heaps, ready to be carried to the scraper. The seed is removed from the brush by various methods, from the best horse-power scraping machines, by which the brush of three acres of corn may be cleaned in a day, down to the original hand machines of the simplest construction. That part of the stalk still remaining in the field should be ploughed under during the fall, or in the following spring. The practice of the Shakers is to break them down with a heavy drag in the spring following, and plough them under, and then run over the ground with a large roller, which process prepares the land again for planting. Some carry their stalks into the cattle or sheep yards, where they become incorporated with the manure, and thereby make a valuable addition to the compost.—When the broom corn was first introduced by the united society of Shakers in Watervliet, N. Y., in the year 1791, it was raised in the garden as other corn. In 1798 it began to excite attention, and some new brooms were manufactured by them for the market, and sold at the price of 50 cents each. The handles were made of soft maple timber, and turned in a common foot lathe. The machinery for manufacturing the brooms was very simple. It consisted of nothing more than a roller or cylinder of wood, turned by a short crank for the purpose of winding on the cord or twine; and by placing one or both feet against this cylinder, the tightness of the twine was governed, and the broom made by holding the handle in one hand, and applying the brush with the other, while winding. The next process, by way of improvement, some few years after, was the addition of a bench to the roller, in a frame fastened to the bench, and a rag-wheel to hold the cord when wound upon the roller by a short crank as before. Nearly all the Shakers' societies in the United States are more or less engaged in this branch of employment; but the societies at Watervliet, N. Y., and that at Union village, O., carry it on the most extensively. The census of the United States for 1870 gives no statistics respecting broom corn.

BROOME, a S. county of New York, bordering on Pennsylvania; area, 680 sq. m.; pop. in 1870, 44,103. It is drained by the E. branch of the Susquehanna, the Chenango, Otselic, and other smaller streams, and traversed by the New York and Erie, the Syracuse and Binghamton, the Albany and Susquehanna, and the Delaware, Lackawanna and Western railroads, and the Chenango canal. The surface is uneven. The valleys are fertile, but the uplands are only fit for grazing. The chief productions in 1870 were 84,926 bushels of wheat, 160,602 of Indian corn, 783,387 of oats, 450,028 of potatoes, 101,955 tons of hay, 2,961,378 lbs. of butter, 72,137 of wool, and 164,809 of hops. There were 7,547 horses, 24,649 milch cows, 14,387 other cattle, 20,134 sheep, and 8,201 swine. Capital, Binghamton.

BROOME, William, an English author, born in Cheshire in 1680, died in Bath, Nov. 16, 1745. In conjunction with Fenton he aided Pope in the translation of the *Odyssey*. He translated books 2, 6, 8, 11, 12, 16, 18, 23; Fenton, 1, 4, 19; the remaining 12 being by Pope. Broome also compiled the notes, and he received £500 for his whole work. He also published some indifferent poetry of his own.

BROSSES, Charles de, or Debrosses, a French author, born at Dijon, Feb. 17, 1709, died in Paris, May 17, 1777. He was early proficient in science, jurisprudence, and literature, spent some time in Italy, was president of the parliaments of Dijon and Burgundy, and a member of the academy of inscriptions and belles-lettres; but having excited the enmity of Voltaire by criticising his *Dictionnaire philosophique*, he was not admitted to the French academy. His principal works are: *Lettres sur l'état actuel de la ville souterraine d'Herculanum*, the earliest publication on that subject (Dijon, 1750); *Histoire des navigations aux terres australes*, written at the request of Buffon, and introducing for the first time the designations Australasia and Polynesia (2 vols., 1756); *Traité de la formation mécanique des langues* (2 vols., 1765); and a collection of about 700 passages of Sallust, with elaborate comments, under the title of *Histoire du septième siècle de la république romaine* (8 vols., 1777). The last volume included a small portion of the original text, the publication of the rest, which was to form a quarto volume, being prevented by his death. *Le président de Brosse, histoire des lettres et des parlements du 18^{me} siècle*, was published in 1842.

BROSSET, Marie Félicité, a French orientalist, born in Paris, Feb. 5, 1802. He was educated for the church, and for three years was a teacher in Jesuit colleges, but abandoned theology and devoted himself to the Semitic and other eastern languages, composing a grammar and dictionary of the Georgian language out of the Georgian version of the Bible, and eking out a scanty subsistence by type-setting and proof-reading. He accepted an assistant professorship of Armenian and

Georgian in the imperial academy of sciences in St. Petersburg, where he became academicien, councillor of state, inspector of primary schools, director of the principal public library, and in 1851 custodian of the collection of oriental coins at the Hermitage palace. He prepared eight volumes (the 13th to the 21st) of the new edition of Lebeau's *Histoire du Bas Empire*, enriching it with original material from oriental sources, and published many geographical, archaeological, and historical works relating to Georgia and Armenia, the principal being *Histoire de la Géorgie* (2 parts, St. Petersburg, 1849-'57) and *Ruines d'Ani, capitale de l'Arménie sous les rois Bagratides aux X^e et XI^e siècles* (2 vols., 1860-'61). His *Rapport sur un voyage archéologique dans la Géorgie et l'Arménie* (St. Petersburg, 1849-'51) narrates his expedition to the Caucasus, Georgia, and Armenia, undertaken under the auspices of the Russian government. He also contributed to Tchubinnoff's Georgian-Russian-French dictionary, to the bulletins and memoirs of the St. Petersburg academy, and to the *Journal Asiatique* of Paris, and translated from Armenian into French Siphannos's *Histoire de Siounie* (St. Petersburg, 1864).

BROTHERS, Richard, an English fanatic, born about 1758, died in London, Jan. 25, 1824. He had been a lieutenant in the British navy for several years, and quitted the service in 1789. Declining to take the usual oath to enable him to draw his half pay, he was in 1790-'91 reduced to great straits, being forced for a time to live in the workhouse. He styled himself "nephew of the Almighty and prince of the Hebrews, appointed to lead them to the land of Canaan," and in 1792 sent letters to George III., the ministry, and the speaker of the house of commons, announcing the fulfilment of the 7th chapter of Daniel. In 1794 he published a book, in two parts, called "A Revealed Knowledge of the Prophecies and Times." Having prophesied the death of the king and the destruction of the monarchy, and foretold that the crown was to be delivered to him, he was imprisoned for some time in Newgate. His disciples were not confined to the poor and ignorant, but included Halhed, the orientalist; William Sharp, the engraver, who executed his portrait, inscribing under it, "Fully believing this to be the man appointed by God, I engrave his likeness;" and other persons of distinction. Many of his followers sold their goods to be ready to accompany him to the New Jerusalem, which was to be built on both sides of the Jordan, and which he was to reach in 1795. Jerusalem was to become the capital of the world, and when the Jews were fully restored, in 1798, he was to be revealed as the prince and ruler of the Jews, and governor of all nations. At last Brothers was committed to Bedlam as a dangerous lunatic. After some delay, application was made to Lord Chancellor Erskine, who granted an order of release on April 14, 1806. Mr. Finlayson,

one of his disciples, then removed him to his own house, where he resided during the last years of his life. Mr. Finlayson, who retained his belief in the mission of Brothers, related these facts in 1848.

BROUCKÈRE, I. Charles Marie Joseph Ghislain de, a Belgian statesman, born at Bruges in 1796, died April 20, 1860. He was educated at the polytechnic school of Paris, entered the Dutch army as sub-lieutenant, but retired in 1820, and was employed in a banking house. In 1825 he was elected deputy to the states general, and at once enlisted in the ranks of the liberals. After the breaking out of the revolution of 1830 he was at the head of the financial department in the provisional government, and suggested the nomination of the duke de Nemours to the throne. Nevertheless, on the election of Leopold, he was called to the ministry of the interior, and subsequently the war ministry was forced upon him. On the opening of the university of Brussels he accepted one of the professorships, declining the salary. From 1835 to 1838 he was president of the Belgian national bank. In 1848 he was again chosen deputy, and soon afterward mayor of Brussels. He had the title of count offered to him by the king in 1857, but declined it. He was an opponent of the Catholic party, and of a protective tariff. **II. Henri Marie Joseph Ghislain de**, brother of the preceding, born at Bruges in 1801. He was attorney general at Roermonde when the revolution of 1830 broke out, in which he took an active part as a volunteer in the army, and as a member, and afterward as secretary, of the national congress. He was one of the commissioners sent to England in 1831 to offer to Leopold the Belgian crown. His most important act as a legislator was the revision of the criminal code, including the abolition of capital punishment.

BROUGHAM, Henry, Baron Brougham and Vaux, lord chancellor of England, born in Edinburgh, Sept. 19, 1779, died in Cannes, France, May 9, 1868. He was descended from an ancient Westmoreland family, and was through his mother the grand-nephew of William Robertson, the historian. He was educated at the high school and university of Edinburgh, where he was distinguished for his devotion to mathematics and physical science. Before he was 20 he wrote several papers which appeared in the "Transactions of the Royal Society." He subsequently travelled on the continent, and was admitted a member of the Edinburgh society of advocates in 1800. He was a member of the "Speculative Club," a debating society which brought him into contact with Horner, Jeffrey, and others, afterward distinguished; and in 1802 he helped to start the "Edinburgh Review," to which he was an assiduous and able contributor for a quarter of a century. In 1803 was published his "Inquiry into the Colonial Policy of the European Powers," which drew much attention. He was called to the bar at Lincoln's

Inn in 1808, and chose the common law courts and the northern circuit. In 1810 he entered parliament as member for Camelford, a rotten borough under the influence of the duke of Bedford. One of his first steps was to introduce a resolution requesting the king to take decisive measures for the suppression of the slave trade. During the next two years he spoke in favor of Roman Catholic emancipation and of reform in the government of India, and in condemnation of flogging in the army. He had previously acquired great popularity by opposing the "British orders in council," and in 1812 was efficient in procuring their repeal. In that year he offered himself as candidate for Liverpool, and was defeated by George Canning, and afterward failed as candidate for Inverkeithing. In 1816 he was returned for the borough of Winchelsea, of which the earl of Darlington was owner; he represented this borough until 1830. He commenced his efforts in the cause of popular education in 1816 by obtaining the appointment of a committee to inquire into the state of the education of the poor in the metropolis. In 1818 he succeeded in getting a commission appointed to inquire into the abuses of the public charitable foundations of the kingdom connected with education, which resulted in the nomination of a permanent commission to supervise the administration of such charities. His "Letter to Sir Samuel Romilly, upon the Abuse of Public Charities," which was published in 1818, ran through ten editions. In 1820 and 1821 he was engaged as counsel of Queen Caroline in her contest with George IV., and gained great popularity by his course in that case. In 1823 he helped to found the London mechanics' institute. In 1825 appeared his "Practical Observations upon the Education of the People, addressed to the Working Classes and their Employers," of which 20 editions were sold. In the same year he was elected lord rector of Glasgow university over Sir Walter Scott, and introduced a bill for the incorporation of the London university, of which he was one of the most active promoters. He was also one of the founders of the "Society for the Diffusion of Useful Knowledge," started in 1827. Mr. Brougham was elected chairman of the managing committee, and his discourse on the "Objects, Pleasures, and Advantages of Science" was the society's first publication. Between 1825 and 1830 he spoke frequently in parliament on law reform, Catholic relief, colonial slavery, and the corporation and test acts. His speech of Feb. 7, 1828, in behalf of law reform, indicated the necessity of almost all the legal reforms which have been effected in England since that period. During the short administration of Mr. Canning, that statesman received Mr. Brougham's support on account of "his liberal and manly foreign policy." In 1830 he resigned his seat for Winchelsea, on the ground of disagreement with his patron, the marquis of Cleveland, and was immediately afterward

returned for Knaresborough through the influence of the duke of Devonshire. At the general election, which ensued upon the accession of William IV., Brougham stood for Yorkshire, and was returned free of expense. At this time he occupied the position of leader of the British people in their efforts for parliamentary reform. On the formation of the ministry of Earl Grey, he became lord chancellor, with the title of Baron Brougham and Vaux, which was conferred on him in November, 1830. In his judicial capacity he was noted for the rapidity of his decisions, which nevertheless were generally accurate. With Earl Grey he bore the principal part in advocating the reform bill in the house of lords. Mr. Roebuck, in his "History of the Whig Party," says that it was owing to Lord Brougham's astonishing audacity and menaces that William IV. was induced to dissolve the house of commons in 1831. All the measures of reform passed by the first reformed house of commons received Lord Brougham's support in the house of lords. The dismissal of the whig ministry in November, 1834, put an end to his chancellorship and his official life. After that time he took an active part in the determination of appeals to the house of peers, was often in antagonism to the whigs, and censured their Canadian policy. His zeal for popular education, the abolition of slavery, the suppression of the slave trade, the repeal of the corn laws, and law reform never slackened. In 1839 he became proprietor of the villa Louise Eléonore, on a beautiful estate in the south of France, near Cannes, overlooking the Mediterranean—his estate in England being Brougham hall, Penrith, Westmoreland, and his London residence No. 4 Grafton street. As an orator Lord Brougham was in his time second only to Canning. In 1833 he was elected a foreign associate of the institute of France, and later of the royal academy of sciences of Naples, and in 1859 was made chancellor of the university of Edinburgh. In 1857 he founded the national association for the promotion of social science, and in 1862 the working men's club and institute union. In 1850, '52, and '53 he made experiments on the properties of light, which were communicated to the British royal society and the academy of sciences at Paris, and published in the transactions of both. In 1855, conjointly with E. J. Routh, he published "An Analytical View of Sir Isaac Newton's Principia." Soon after his loss of office he brought out, in conjunction with Sir Charles Bell, an annotated edition of Paley's "Natural Theology." In 1839-'43 appeared his series of "Sketches of Statesmen who flourished in the time of George III.," and in 1845 his "Lives of Men of Letters and Science who flourished in the time of George III." His "Speeches on Social and Political Subjects," with a historical introduction, appeared at London and Glasgow in 1857, in 2 vols. 12mo. Among the later productions of Lord Brougham are a valuable dissertation,

read by him, May 18, 1858, before the French academy, on "Analytical and Experimental Inquiries on the Cells of Bees," and his speech, delivered June 17, 1858, in the house of lords, on the suppression of the slave trade. A complete edition of his works, in 10 volumes, was published in 1857 under his own supervision; and after his death appeared "The Life and Times of Lord Brougham, written by Himself" (3 vols., London and New York, 1871). A novel ascribed to him, entitled "Lunel," was published in 1872.

BROUGHAM, John, an Irish actor and playwright, born in Dublin, May 9, 1810. He was intended for the medical profession, but the prospect of a government clerkship took him to London, where, being disappointed in this hope, he gave lessons in drawing for some time, and finally became an actor at the Olympic theatre, and subsequently at the Haymarket, where he made a very successful first appearance in June, 1832. In 1842 he came to America, appeared at the Park theatre, New York, and subsequently performed in almost every theatre in the Union. Having managed a theatre in Boston, he built the Lyceum (afterward Wallack's) in New York in 1850, but relinquished it at the end of two seasons. He also managed the Bowery theatre, New York, in 1856-7. About 1860 he visited England, returning in 1865, since which time he has been mainly engaged in New York. Mr. Brougham is the author of various comedies, dramas, and extravaganzas, the most popular of which are "Pocahontas," "Romance and Reality," "My Cousin German," "David Copperfield," "Dombey and Son," adapted from Dickens, and "The Lily of France" (1872). He has collected some of his fugitive prose stories and articles into two volumes, called "A Basket of Chips" and "The Bunsey Papers."

BROUGHTON, Lord. See HOBHOUSE.

BROUSSA. See BRUSA.

BROUSSAIS, François Joseph Victor, a French physician, born at St. Malo, Dec. 17, 1772, died at Vitry, near Paris, Nov. 17, 1838. His early years were passed at a small village where his father was a physician. At the age of 12 he was sent to school at Dinan, where he was pursuing his studies when the revolution broke out in 1789. He was enrolled as a volunteer, and joined the army. After two years he obtained leave to return home, on account of sickness. On his recovery he became a student of medicine, and obtained a commission as surgeon on a ship of war. He held an appointment at Brest from 1795 to 1798; but being anxious to pursue a course of study at Paris, he removed there in 1799. He obtained an appointment as military surgeon in 1804, and two years later was sent to the camp at Boulogne; but the project of invading England being abandoned, the army was turned against Austria, and Broussais went with it in all its campaigns. In 1808 he obtained leave to go to Paris to superintend the publication of his *Histoire des phleg-*

masies chroniques. This work, which contains the germs of all his future doctrines, met with little notice at the time; for, although Pinel praised it highly, and it was honorably noticed by the institute, nearly the whole edition remained unsold till 1816. Soon after this publication, in 1808, he was appointed chief physician to a division of the French army in Spain, where he remained six years, pursuing his researches and attending to the duties of his office. In 1814 he was appointed assistant professor at the military hospital of the Val de Grâce in Paris. He commenced a course of lectures on practical medicine, in which he attempted to form a system and a school of his own, in opposition to the doctrines of Pinel, then taught in the established schools of medicine. His lectures were attended by great numbers of students, who accepted his ideas with enthusiasm. In 1816 he published his *Examen de doctrine médicale généralement adoptée, &c.*, which excited the opposition of the whole medical faculty. By degrees his doctrines gained approval, and were taught in the medical school itself long before 1832, when Broussais was appointed professor of general pathology in the academy of medicine, which office he held until his death. Besides the two works above mentioned, he published in 1824 his *Traité de la physiologie appliquée à la pathologie*; in 1829, his *Commentaires des propositions de pathologie consignées dans l'examen*; in 1832, *Le choléra morbus épidémique*.—The life of Broussais presents three distinct periods. In the first, he labored to prove that the doctrines of Pinel with regard to the essentiality of fever were erroneous, and that some morbid agent, producing irritation and inflammation, was the cause of all disease. From 1816 to 1821 he was successfully occupied in controverting the established theories from this point of view. His followers then complained that he had shown the fallacy of Pinel's theory, but had not sufficiently elaborated a new doctrine to replace it. From 1821 to 1828 he labored to establish what he called the "physiological system of medicine," in opposition to the "ontological" system of Pinel. The "History of Chronic Inflammations" had prepared the way for his theory of irritation in the organs, corresponding to a principle of irritability in the organism. He therefore proclaimed this doctrine as the basis of all medical truth, and sustained his views with ability and general success from 1821 to 1828. It was the doctrine taught by Brown in Edinburgh more than 30 years before, and had already met with much success in England, Germany, and Italy, though little known in France until revived by Broussais under a new form. For seven years Broussais had immense success in France and Belgium, where this theory was practically new. In England and Germany it met with less success, because it had been known as the doctrine of Brown; and though very true in many points, it was nevertheless insufficient to

explain all the phenomena of health and disease. The same opinion arose in France after a seven years' practical trial of the system; and after being greatly lauded and admired, Broussais was deserted by the students and professors of medicine. The partial truth of his views was admitted, but other principles and doctrines were needed to explain the physiological and pathological phenomena of life. In nervous diseases it afforded no assistance, but left the student as much in the dark as he was before; and this was admitted by his own partisans, and partly by Broussais himself. To make his system more complete, he undertook a series of observations on the nervous system, and its relation to psychology. Although he had been up to that time more or less opposed to phrenology, he turned his attention to the subject, gave public lectures on it, and in 1836 published an octavo volume under the title of *Cours de phrénologie*. This work had a temporary popularity, but failed to make an abiding impression. Broussais's theory was on the wane, as a partial view of truth, not containing a complete and unitary principle of science.

BROUSSON, Claude, a French Protestant martyr, born in Nîmes in 1647, put to death in Montpellier, Nov. 4, 1698. He was an advocate at Castres and Toulouse, and displayed great ability in defending the Huguenots. After the interdiction of the Protestant synods, 16 deputies of the principal Protestant communities of France assembled at his house in 1683; these meetings were subsequently called *les assemblées du désert*. The outbreak which resulted from these meetings compelled Brousson to leave Toulouse; and barely escaping arrest at Nîmes, he fled to the Cévennes, and thence to Switzerland. With many Protestant ministers of the Cévennes he was hanged in effigy, July 8, 1684, in the market place of Nîmes. Returning to the Cévennes, he was ordained under the name of Paul Beausocle, and remained there as an itinerant preacher, amid great perils, till December, 1693, when he returned to Switzerland, after addressing to the governor of the province of Languedoc, who had put a price upon his head, a *lettre apologétique*, in reply to the charge of being a disturber of the public peace. In November, 1695, he ventured into France, by way of the Ardennes; but being recognized, he fled again to Switzerland, proceeding thence to the Netherlands, where the government gave him a pension. In 1697 he recrossed the frontier, entering France by the Jura mountains, and the next spring he was again preaching in the Cévennes. After narrow escapes he was arrested and sent to Montpellier, where he was broken on the wheel, upon the ground of alleged treasonable coöperation with the count de Schomberg in the scheme of invading France. His principal works are: *L'état des réformés de France* (3 vols., the Hague, 1684); *Lettres au clergé de France* (1685); *Lettres des Protestants de France à tous les autres Protestants de l'Europe* (Berlin, 1688); *Lettres au*

Catholiques romains (1689); *Relation sommaire des merveilles que Dieu fait en France dans les Cévennes, &c.* (1694). His biography was published at Utrecht in 1701.

BROUSSONNET, Pierre Auguste, a French physician and naturalist, born at Montpellier, Feb. 28, 1761, died there, July 27, 1807. He was the first who introduced the botanical system of Linnæus into France. He caused the first flock of merino sheep to be brought from Spain, and the first Angora goats from the Levant. In 1789 he became a member of the national assembly, and in 1792 of the convention; but, incurring the suspicions of the terrorists, he in 1793 escaped to Madrid. Here, having had no opportunity to secure any of his property, he was reduced to great poverty when Sir Joseph Banks, whose acquaintance he had made during a three years' residence in England, sent him a gift of \$5,000, and procured him a passage to India in an English ship. The vessel in which he had embarked was forced into Lisbon harbor by a storm, and finding that his old political associations exposed him even here to fresh persecutions, he passed over to Africa, where he procured employment as a physician at Morocco, and resumed his botanical and zoological studies. Under the empire he was appointed French consul at Mogadore and the Canaries; and in 1805, on his return to France, he was made a member of the legislative body. He belonged to the principal learned societies of France, and was the author of several botanical, zoological, and medical works of great value; the most important of them is his *Ichthyologia, seu Piscium Descriptiones et Icones* (London, 1782), which, however, he left unfinished, only one volume having been published.

BROWN, the name of counties in seven of the United States. **I.** A W. central county of Texas, intersected by Pecan bayou, and bounded S. by the Colorado river and W. by Jim Ned creek; area, 1,060 sq. m.; pop. in 1870, 544, of whom 37 were colored. The surface is undulating and hilly, with occasional tracts of rolling prairie, the soil of which is very rich. Stock-raising forms the chief occupation of the inhabitants. In 1870 there were 77 horses, 378 milch cows, 13,583 other cattle, 630 sheep, and 1,875 swine. Capital, Brownwood. **II.** A S. W. county of Ohio, separated from Kentucky by the Ohio river; area, 502 sq. m.; pop. in 1870, 30,802. The surface near the river is hilly, but in other portions level or gently undulating. The soil is fertile and well cultivated. The chief productions in 1870 were 199,605 bushels of wheat, 926,168 of Indian corn, 196,305 of oats, 13,587 tons of hay, 2,687,743 lbs. of tobacco, 62,756 of wool, 519,771 of butter, 51,684 gallons of sorghum molasses, and 10,776 of wine. There were 8,113 horses, 6,326 milch cows, 8,721 other cattle, 19,268 sheep, and 28,720 swine. Capital, Georgetown. **III.** A S. county of Indiana, watered by Bean Blossom and Salt

creeks; area, 320 sq. m.; pop. in 1870, 8,681. Its surface is diversified, and the soil is generally productive. Much of the land is well wooded. The chief productions in 1870 were 83,056 bushels of wheat, 197,784 of Indian corn, 61,139 of oats, 2,348 tons of hay, 24,498 lbs. of wool, and 65,765 of tobacco. There were 2,062 horses, 1,391 milch cows, 2,141 other cattle, 8,404 sheep, and 7,100 swine. Capital, Nashville. **IV.** A W. county of Illinois, bounded E. by the Illinois river; area, 320 sq. m.; pop. in 1870, 12,205. The surface is occupied partly by prairies and partly by woodlands. The soil is fertile and well cultivated. The Toledo, Wabash, and Western railroad passes through the county. The chief productions in 1870 were 130,778 bushels of wheat, 337,769 of Indian corn, 70,852 of oats, 5,633 tons of hay, and 26,439 lbs. of wool. There were 3,434 horses, 2,258 milch cows, 4,864 other cattle, 9,525 sheep, and 16,208 swine. Capital, Mount Sterling. **V.** An E. county of Wisconsin, at the head of Green bay, intersected by Fox or Neenah river; area, 525 sq. m.; pop. in 1870, 25,168. The surface is uneven and some of the soil fertile. The Wisconsin division of the Chicago and Northwestern railroad passes through it. The chief productions in 1870 were 164,227 bushels of wheat, 16,498 of rye, 13,152 of Indian corn, 153,953 of oats, 68,329 of potatoes, 19,525 tons of hay, and 309,838 lbs. of butter. There were 2,479 horses, 4,267 milch cows, 4,685 other cattle, 5,216 sheep, and 5,331 swine. Capital, Green Bay. **VI.** A S. county of Minnesota, bounded N. E. by the Minnesota river, and intersected by the Big Cottonwood and Little Cottonwood; area, 450 sq. m.; pop. in 1870, 6,396. There are several lakes in the S. part. The chief productions in 1870 were 213,270 bushels of wheat, 34,525 of Indian corn, 156,768 of oats, 24,448 of barley, 16,520 tons of hay, and 94,993 lbs. of butter. There were 1,202 horses, 2,155 milch cows, 3,631 other cattle, 995 sheep, and 1,796 swine. Capital, New Ulm. **VII.** A N. E. county of Kansas, bordering on Nebraska; area, 576 sq. m.; pop. in 1870, 6,823. It is drained by Grasshopper creek and other affluents of the Missouri. The St. Joseph and Denver City railroad crosses the county. The chief productions in 1870 were 62,619 bushels of wheat, 614,268 of Indian corn, 128,136 of oats, 57,961 of potatoes, 12,582 tons of hay, and 181,257 lbs. of butter. There were 3,004 horses, 2,767 milch cows, 5,141 other cattle, 2,590 sheep, and 7,900 swine. Capital, Hiawatha.

BROWN, Benjamin Gatz, an American journalist and statesman, born in Lexington, Ky., May 28, 1826. He is a member of a family of Virginian origin, the son of Mason Brown, and grandson of John Brown, United States senator from Kentucky. He graduated at the Transylvania university in 1845 and at Yale college in 1847, studied law at Louisville, and about 1850 took up his residence in St. Louis. He was a mem-

ber of the Missouri legislature from 1852 to 1858, and in 1857 delivered a speech which was regarded as initiating a movement in behalf of emancipation in that state. In 1854 he established the "Missouri Democrat," which subsequently led the Benton democracy through all phases of free-soilism, until it expanded into the republican party of Missouri. At the outbreak of the civil war he raised a regiment which assisted in the capture of Fort Jackson, and afterward commanded a brigade of militia. He promoted the act of emancipation of 1864. From 1863 to 1867 he was United States senator from Missouri, and in 1870 was elected governor of the state. In 1872 he was nominated for vice president of the United States, on the ticket headed by Horace Greeley, by the liberal republican convention at Cincinnati and the democratic convention at Baltimore.

BROWN, Charles Brockden, an American novelist, born in Philadelphia, Jan. 17, 1771, died Feb. 22, 1810. His ancestors were Quakers who came over with William Penn. At 11 years of age he was placed under the care of Mr. Robert Proud, author of a "History of Pennsylvania," and from him he derived a knowledge of the classics. He left Mr. Proud's school before he was 16, and soon afterward drew up the plan of several epics on the discovery of America and the conquest of Mexico and Peru. Neither of them was ever published, nor do any fragments of them remain. He determined to pursue law, but presently abandoned the profession for literature. The first of his novels was "Wieland," issued in 1798, and in 1799 he published "Ormond." These two novels were successful, and until Cooper produced his works there were no American fictions to compare with them. His third novel, "Arthur Mervyn, or Memoirs of the Year 1793," depicts the scenes in Philadelphia during the prevalence of the yellow fever. "Edgar Huntley, or the Adventures of a Sleep-walker," was published not long afterward. The scene of this story, as of "Wieland," is laid in Pennsylvania. In 1800 he published the second part of "Arthur Mervyn;" in 1801, "Clara Howard;" and in 1804, "Jane Talbot." From April, 1799, to the close of 1800, he conducted the "Monthly Magazine and American Review." In 1803 he commenced the "Literary Magazine and American Register," which he continued five years; and in 1806 he commenced a semi-annual "American Register," of which he published five volumes. A collection of his novels in 7 vols. was published in Boston in 1827. Another edition in 6 vols. appeared in Philadelphia in 1857.

BROWN, Ford Madox, an English painter, born at Calais, France, in 1821. He studied his art in Belgium and Paris, and sent two cartoons to the competition in Westminster hall in 1844, and a cartoon and fresco in 1845. After visiting Italy he painted "Wycliffe reading his Translation of the Scriptures," and in the following year exhibited "King Lear" and the "Young

Mother." He produced in 1851, at the royal academy, a large painting of "Chaucer reciting his Poetry at the Court of Edward III." "Christ washing Peter's Feet," exhibited in 1852, gained the prize of the Liverpool academy in 1856. One of his latest works is entitled "The English Fireside."

BROWN, Gould, an American grammarian, born in Providence, R. I., March 7, 1791, died at Lynn, Mass., March 31, 1857. He was a teacher for over 20 years in the city of New York. His "Institutes of English Grammar" appeared in 1823; in the same year he also published "First Lines of English Grammar." His "Grammar of English Grammars" (large 8vo, 1851) was the most extensive and complete grammar of the English language, and has continued to enjoy a high reputation. A revised edition, which he had just completed at the time of his death, appeared in 1857.

BROWN, Henry Kirke, an American sculptor, born at Leyden, Mass., in 1814. His first attempt at art was made at the age of 12, in the portrait of an old man. At 18 he went to Boston to study portrait painting, but soon turned his attention to sculpture. Having spent some time in Italy, he returned to America and fixed his residence in Brooklyn, N. Y., applied himself to the casting of bronze, and produced the first bronze statue ever cast in this country. He has completed several well known works in marble, "Hope," the "Pleiades," the "Four Seasons," and the statue of Gen. Nathaniel Greene in the capitol at Washington. In bronze he has executed a statue of De Witt Clinton, the equestrian statue of Washington in Union square, New York, the statues of Lincoln in Brooklyn and New York, and an equestrian statue of Gen. Scott in Washington.

BROWN, Hugh Stowell, an English clergyman, born at Douglas, Isle of Man, in 1823. At the age of 15 he went to England to learn land surveying, and two years afterward went to Wolverton to learn engineering, and became an engine driver on a railroad. It was his habit, after his day's work was done, to spend several hours in study, and he wrote his first classical exercises with chalk upon the fire box of the engine. Becoming of age, he entered King's college in his native town, where he remained three years. Entertaining doubts as to some of the doctrines of the established church, he joined the Baptist denomination, and in 1848 was appointed minister of a chapel in Liverpool, and soon became the leader of the denomination in that city. He is a popular lecturer to the working classes, large numbers of whom attend his Sunday afternoon services. His published lectures have had a large sale.

BROWN, Jacob, an American general, born in Bucks co., Penn., May 9, 1775, died in Washington, Feb. 24, 1828. He was descended from members of the society of Friends; supported himself in early life by teaching school; was also employed for some time as a surveyor of public lands in Ohio; and settled in Jefferson

co., N. Y., then a wilderness, in 1799. He was a militia general in 1812; was soon after appointed brigadier general in the regular army, and in 1814 major general; assisted in the defence of Sackett's Harbor in 1813; and in the following year exhibited much bravery in the battles of Chippewa and Niagara Falls, and at the siege of Fort Erie, receiving the thanks of congress and a gold medal. At the termination of the war he continued in the army as major general, succeeding in 1821 to the chief command.

BROWN, John, an English author, born at Rothbury, Northumberland, Nov. 5, 1715, killed himself, Sept. 23, 1766. He was educated at Cambridge, and during the rebellion of 1745 acted with much gallantry as a volunteer on the royal side. He afterward became rector successively at Moreland, Great Horkesley, and Newcastle. He was preparing to go to Russia, on the invitation of Catharine II., to aid in establishing a system of education, when an attack of gout and rheumatism caused him to commit suicide. His works include "Essays on the Characteristics of the Earl of Shaftesbury," a tragedy called "Barbarossa," an "Estimate of the Manners and Principles of the Times," which passed through seven editions in one year, a "History of the Rise and Progress of Poetry," and "Thoughts on Civil Liberty, Licentiousness, and Faction."

BROWN, John, a Scottish Biblical critic, born in Perthshire about 1722, died at Haddington, June 19, 1787. While tending sheep on a farm he learned to read, and soon mastered the Latin, Greek, and Hebrew languages. At the age of 26 he opened a school, with the intention of becoming a minister of the Scottish church. He sided with the party who seceded from the church soon after, was ordained, and became pastor of a small Secession congregation in Haddington. Here he learned the Italian, Spanish, German, Dutch, French, Arabic, Persian, Syriac, and Ethiopic languages. His principal works are, a "Dictionary of the Bible," a "Self-Interpreting Bible," and a "History of the British Churches."

BROWN, John, a Scottish physician, founder of the Brunonian system, born in Berwickshire in 1735, died in London, Oct. 7, 1788. He was the son of a poor farmer, and was early apprenticed to a weaver; but having previously manifested much aptitude for study at the grammar school of Dunse, the schoolmaster offered to instruct him gratuitously. The schoolmaster and the parents of Brown belonged to a body of Presbyterian seceders, and young Brown was destined for the ministry. While pursuing his studies he was induced to attend a meeting of the synod of the established church at Dunse, and this gave such offence to his friends that he left the society and joined the established church. He then became private tutor in a gentleman's family, and acted as an assistant in the grammar school. In 1755 he went to Edinburgh, and after passing

through the preliminary classes, entered himself as a student of divinity in the university. For some time he supported himself by private teaching, and then resumed his labors as assistant teacher at Dunse, where he remained about a year. In 1759 he returned to Edinburgh, renounced the study of theology, and commenced that of medicine, supporting himself by giving private instruction in Latin to medical students. Dr. Cullen employed him as a private tutor in his own family, and recommended him to others, but opposed his nomination to a professorship, whereupon Brown began to attack the doctor's medical views. Having quarrelled with the professors at Edinburgh, he took his degree of M. D. at St. Andrew's. In 1780 he published his *Elementa Medicinæ*, which contains the doctrines he propounded in opposition to the views of Dr. Cullen, and for several years he continued to explain these doctrines in public lectures. The excitement produced by this work was very great in all the medical schools of Europe; and in Edinburgh two hostile camps were formed among the students, under the names of "Cullenites" and "Brownites." The contest sometimes raged with so much violence as to lead to collisions among the younger partisans. In 1786 Brown went to London, where he opened a private school of medicine, and gave lectures in his own house in Golden square. His family was large, and his habits intemperate; his expenses were greater than his income, and being involved in debt, he was confined in the king's bench prison during several months, until released by the assistance of some of his friends. His doctrines had gained many converts in the medical schools abroad, and he was making preparations to leave England for the continent, when he died of apoplexy.—The publication of his first work was followed in 1781 by "An Inquiry into the State of Medicine, on the Principles of the Inductive Philosophy." In 1787 he published "Observations on the Principles of the Old System of Physic." A complete edition of his works (3 vols. 8vo) was published in London by his son, William Cullen Brown, in 1804. The basis of Brown's medical theory is the doctrine of "excitability." In his view, the human organism, in common with that of animals, mainly differs from inorganic bodies by the property of being excited under the influence of external agents, or the functions of internal organs, peculiar to organic life. The physical external agents which excite the organism to act are heat, light, air, and alimentary substances; internally, the blood and the humors which are drawn from the blood. Those functions of the organs which produce a similar effect, according to this theory, are muscular contractions, the various secretions of the body, the passions, and the energy of the brain in the processes of thought. These are what Brown terms the stimulating or exciting forces, which, collectively considered, produce life; and when this influence ceases,

death ensues. The state of health consists in a proper equilibrium between the exciting forces and the vital principle of excitability within the organism; disease consists in the rupture of this equilibrium. Two kinds of excess may disturb the equilibrium of health, and hence all diseases may be classed under two general heads: those produced by an excess of the stimulating forces, and those resulting from an insufficiency of stimulation. The one are called "sthenic" (Gr. *σθένος*, strength), and the other "asthenic," from the want of force. The treatment consists in diminishing the excess of stimulus in one case, and supplying that which is deficient in the other. His doctrines became very popular for a time all over Europe. Girtanner spread them in Germany, and Rasori in Italy. Broussais developed similar views in another form, 30 years later, in France, attributing the origin of all diseases to inflammatory action in the organism, and substituting the word "irritability" in lieu of "excitability," but adopting Brown's division of all diseases into two classes, "sthenic and asthenic." The exaggerations of these two schools have lost their influence on many minds, but the words which mainly characterized their doctrines, as stimulants and contra-stimulants, irritability and excitability, sthenic and asthenic, are still common in the medical vocabulary.

BROWN, John, an American officer, born at Sandisfield, Berkshire co., Mass.; Oct. 19, 1744, died Oct. 19, 1780. He graduated at Yale college in 1771, and officiated as king's attorney at Caughnawaga, N. Y. In 1775 he went into Canada, disguised as a horse trader, to excite the people to unite with the other colonies in the revolution. He was with Ethan Allen at the capture of Ticonderoga, and on Sept. 24 following took Fort Chambly. He was also at Quebec when Montgomery fell. In 1776 he was promoted to the rank of lieutenant colonel, and during the next year was conspicuous on the shores of Lake George. He was killed by the Indians while marching to rescue Schuyler in the Mohawk valley campaign.

BROWN, John, a Scottish divine, born near Whitburn, Linlithgowshire, July 12, 1784, died Oct. 13, 1858. He was ordained pastor of the Burgher congregation at Biggar in 1806. In 1821 he removed to Edinburgh, and was chosen professor of divinity in 1834. As a preacher he was among the first of his time. His principal works are: "The Law of Christ respecting Civil Obedience, especially in the Payment of Tribute;" "The Resurrection of Life;" and "Expository Discourses on the Epistles of Peter, on the Epistle to the Galatians, and on the Epistle to the Romans."

BROWN, John, a Scottish author, son of the preceding, born in Biggar, Lanarkshire, in September, 1810. He was educated at the high school and the university of Edinburgh, where he received the degree of M. D. His literary reputation rests on a series of papers contributed to the "North British Review"

and other periodicals, many of which, on professional and other subjects, have been republished under the title of "*Horæ Subsecivæ*" (2 vols.). Among the most popular of these are several relating to the character and habits of the dog, an animal held by him in peculiar esteem. That entitled "*Rab and his Friends*" has been frequently published in separate form, and is perhaps the best known and most popular of his writings.

BROWN, John, an American abolitionist, born in Torrington, Conn., May 9, 1800, hanged at Charlestown, Va., Dec. 2, 1859. He was fifth in descent from Peter Brown, who landed at Plymouth, Mass., from the *Mayflower* in 1620. At the age of five years he emigrated with his father to Hudson, Ohio, where his youth and early manhood were passed. When a boy he was often sent distances of 100 miles or more in charge of droves of cattle, and visiting several encampments of American troops during the war of 1812, he acquired so great a disgust for military life that he invariably refused to perform military duty, choosing rather to be fined than to serve as a soldier even in time of peace. He then resolved never to take part in any war which was not one for liberty. About this time, as appears from a fragment of an autobiography left by him, he conceived that detestation of slavery which became the master passion of his life. He received a strict religious education, and at 16 years of age was a communicant of the Congregational church and a diligent reader of the Bible. In 1819 he went to Plainfield, Mass., with a view of entering the orthodox Calvinistic ministry; but a chronic inflammation of the eyes compelled him to abandon his studies and return to Ohio, where he resumed the tanner's trade, which he had previously practised in his father's service. For the next 20 years he carried on this business partly in Ohio and partly in Crawford county, Penn.; but having lost the greater part of his property by unfortunate speculations in land, he returned to Ohio, and in 1840 embarked in the wool trade. In 1846 he removed with his family to Springfield, Mass., where he opened a wool warehouse. Many wool-growers of northern Ohio consigned their stock to him to be sold at discretion; but having attempted to establish a system of grading wools, he brought himself into collision with the manufacturers of New England, who combined to purchase wool directly from the producers. Brown thereupon took a large quantity of wool to Europe, which was sold in London at half its value, and he returned to America a ruined man. In 1849 he removed his family to North Elba, Essex county, N. Y., and began to reclaim a tract of wild land given to him by Gerrit Smith. For ten years previous to this time he had harbored the thought of becoming the liberator of the southern slaves; and as the region in which he settled was partially occupied by negro colonists, whom Mr. Smith's liberality had planted there on

free homesteads, he undertook to counsel and instruct them, hoping thereby to further indirectly the scheme which lay nearest to his heart. But the negroes, unaccustomed to the rigors of a northern climate, and disheartened by the toils and hardships involved in clearing their mountain farms, soon relinquished them. Brown and his family, which now included a number of grown-up sons and daughters, persevered, and ultimately established comfortable homes for themselves. In 1851 he returned to Ohio and again engaged in the wool business. In 1854 his four eldest sons, residing in Ohio, migrated to Kansas. They went unarmed, and settled in Lykins county, about 8 m. distant from the village of Ossawatimie, and near the Missouri border. Partaking strongly in the anti-slavery opinions of their father, they were harassed, plundered, and threatened by marauding bands of pro-slavery men from Missouri; and they finally wrote to their father to bring them a supply of arms and ammunition. To this summons he lent a ready ear. Having brooded for fifteen years over schemes for arresting and overthrowing the slave power, he conceived that the moment had now arrived when he ought to take the field actively in that behalf. Trained by a life of toil to endure hardships, tough and sinewy of body, strictly temperate in his habits, and a brave, resolute, and God-fearing man of the type of his Puritan ancestor, he was singularly fitted to become a leader in the rough encounters which marked the border warfare of Kansas in 1854-'6. Moving his family back to the farm in North Elba, he departed in 1855 for Kansas, with no intention of settling there, but prepared to lay down his life if necessary in the anti-slavery cause. In November of this year the people of Lawrence, the headquarters of the free-state men, armed themselves to repel an attack from a large body of Missourians, who, organized as Kansas militia, had laid siege to the town. While the hostile forces were watching each other, John Brown, accompanied by his four sons, all armed to the teeth, appeared among the besieged. He received a command and counselled an immediate movement upon the enemy; but the leaders of the free-state men, unwilling to bring on a collision, were endeavoring to adjust the difficulty by negotiation. This disgusted Brown, who, in reply to an invitation from Gen. J. H. Lane to attend a council of war, said: "Tell the general when he wants me to fight to say so; but that is the only order I will ever obey." Thenceforth his operations were of an irregular character and conducted exclusively by himself. In May, 1856, at the head of a small body of determined men, he went into camp on the Pottawattamie, near the residence of his sons. A few days later he was engaged in the combat of Black Jack, which resulted in the capture of a superior force of Missourians, with a considerable amount of plundered goods. Other affairs of the kind occurring during the

summer enhanced his reputation as a partisan leader and hard fighter, and he was both hated and feared by the pro-slavery marauders. In the latter part of August a fresh invasion of Missourians poured into the territory, numbering nearly 2,000 men. A part of this force was driven back by Gen. Lane, while another body of 500 marched upon the town of Ossawatimie, near which Brown was encamped with about 30 men. Owing to the rapid advance of the assailants, a part of his band was cut off and one of his sons killed; but with the remainder, about 15 men, he took post in the woods adjoining the town, where for nearly an hour he offered an obstinate and successful resistance. When by various casualties his little force had become diminished one half, he effected a retreat in safety, having inflicted a severe loss in killed and wounded on the enemy. This encounter gave Brown a sort of national reputation, and the sobriquet of "Ossawatimie Brown" clung to him until his death. Six weeks later he was again in Lawrence, on his way home from Topeka, when the announcement was made that an overpowering force of Missourians was approaching to attack the town, which at the moment contained fewer than 200 able-bodied men. Brown was unanimously chosen leader, and having made a characteristic speech to his men, whom he urged to fire deliberately and aim at the enemy's legs, he posted his force in and around the town. The enemy approached within half a mile, but hesitated to make an attack, and both parties lay on their arms during the night. When the sun rose the Missourians had decamped. Soon afterward Brown, accompanied by his three sons, left for the east to obtain arms and supplies for the free-state emigrants in Kansas. He remained away a year. In February, 1857, he addressed a committee of the Massachusetts legislature, appointed to consider petitions in favor of a state appropriation to protect the rights of Massachusetts citizens in Kansas; and in Boston and other cities he had frequent interviews with anti-slavery sympathizers. The mission proved an unsuccessful one so far as substantial aid was concerned. His proposition to drill and equip a body of men for service in Kansas savored too much of aggressive warfare to meet the views of most of those to whom he addressed himself. None could doubt his honesty and devotion to the anti-slavery cause, but few were willing to trust a man whose enthusiasm for freedom evidently bordered on fanaticism. Many persons believed him to be insane on the subject. In November, 1857, he returned to Kansas and began to put into practical operation a project in furtherance of the anti-slavery cause far in advance of any views previously made public by him. This was nothing less than to attack the institution of slavery in one of its oldest seats, and by the aid of liberated slaves to overthrow it throughout the Union. This project, conceived many years previous, was matured partly

during the border warfare in Kansas and partly while on his visit to the eastern states; but he unfolded it very cautiously, and would probably have hesitated to carry it out so soon had not his zeal been inflamed by the exciting scenes through which he had recently passed. He revealed it to few if any of those from whom he solicited aid in behalf of the free-state cause. With a small number of resolute men, carefully selected, he soon after repaired to Iowa, where they passed the winter of 1857-'8 in practising military exercises. He now informed his followers that they were to serve in Virginia instead of Kansas, as they had supposed, and that Harper's Ferry would be the scene of his first operations against the slaveholders. For the furtherance of his plans Brown relied very considerably upon the assistance of fugitive slaves who had escaped from the United States into Canada; and for the purpose of informing these people of his intentions and of inducing them to coöperate with him, he called a secret convention of the "friends of freedom" at Chatham, Canada West, in May, 1858. The result of its deliberations was the adoption of a "Provisional Constitution and Ordinances for the People of the United States," drafted by Brown, and which was essentially an embodiment of his political opinions. The preamble declared that the instrument was framed mainly in the interests of the slaves and other people "degraded by the laws of the United States," and many of the articles provided for the maintenance of order among insurgent slaves and for other contingencies which seemed likely to arise. One of them disclaimed any intention to overthrow the government of the United States or dissolve the Union, and limited the action of the framers to "amendment and repeal." Under this constitution Brown was chosen commander-in-chief; J. H. Kagi, secretary of war; Owen Brown, son of John Brown, treasurer; and Richard Realf, secretary of state, the three last named being members of Brown's party from Iowa. No person being permitted to hold more than one office at a time, the presidency was temporarily conferred upon Elder Monroe, a colored clergyman. Brown had hoped to proceed at once to Harper's Ferry, but several circumstances combined to prevent the immediate execution of his plan, the chief obstacle being the want of money. He therefore returned in June, 1858, with a portion of his party, to Kansas, and settled temporarily in the southern part of the territory, which was then the theatre of border warfare, as northern Kansas had been a year or two previous. On Dec. 19, while the excitement was at its height, a slave named Jim secretly crossed the border to Brown's cabin and announced that he and his family had been sold, and would be sent to Texas the next day. Brown, with 20 men divided into two parties, immediately crossed over into Missouri and liberated the slaves, whom, with 6 other negroes, making 11 in all, they

conveyed into Kansas. In this enterprise one of the owners of the slaves was killed. An unprecedented excitement followed. Not only was a large reward offered for Brown's arrest, but the more moderate free-state men hastened to disavow any sympathy with his daring act. The territory became too hot for him, and he started early in January, 1859, for the north, accompanied by four white companions and the liberated negroes. Pursued by a party of 30 men, subsequently increased to 42, he made a stand in a deserted log cabin, whence, having provided for the safety of the women and children under his charge, he issued forth with seven male companions to do battle with the enemy. The latter precipitately fled, with the exception of four men, who were at once made prisoners. Brown subsequently took the slaves into Iowa, whence in the middle of March he conveyed them safely to Canada. He now began in earnest his preparations for the invasion of Virginia. In the latter part of June he appeared in Hagerstown, Md., where he represented himself to be a farmer named Smith from western New York, in search of a cheap farm adapted to wool-growing. He finally hired for a few months an unoccupied farm in Virginia, about six miles from Harper's Ferry, which he occupied with several of his party early in July. Others joined him from time to time, including three of his sons, until the force numbered 22 persons, of whom 17 were white men and the remainder negroes. Boxes of arms, ammunition, and other supplies which had been shipped to Chambersburg, Pa., the previous year, were gradually removed to the farm in Virginia, without exciting the suspicions of the neighbors. In selecting this place for the first attack Brown had for his immediate object the capture of the United States arsenal at Harper's Ferry, where were usually stored from 100,000 to 200,000 stand of arms. This building with its contents once in his possession, he expected to rally to his support the slave population of the neighborhood, and, when his force was sufficiently recruited and equipped, to convey them into the free states, or, if that should prove impossible, to retire to the mountains and inaugurate a general servile war. The night of Oct. 24 was originally fixed for the attack upon the arsenal, but at a council called by Brown on Sunday, the 16th, it was determined to begin operations that very evening. The presence of so large a party of men in the neighborhood with no ostensible object had begun to arouse the suspicion of the Virginians, and further delay was considered dangerous. About 10 o'clock on Sunday night Brown and his men entered the village of Harper's Ferry, and, having extinguished the lights on the streets, took possession of the arsenal, overpowering and making prisoners the three watchmen who formed the sole guard of the building. The watchman at the bridge across the Potomac was next captured, and the railroad train from the west, which

arrived there shortly after 1 A. M. on the 17th, was stopped. During the night the houses of Col. Washington and other citizens in the neighborhood were visited and stripped of whatever arms they contained, the owners were imprisoned in the arsenal, and their slaves were freed. At daylight on the 17th the train was allowed to proceed toward Baltimore, Brown freely informing every one who questioned him that his object in seizing the arsenal was to free the slaves, and that he acted "by the authority of God Almighty." As the morning advanced he gathered in prisoners, principally from among the male citizens who appeared upon the streets and the workmen who approached the arsenal to resume their daily avocations. By 8 o'clock the number exceeded 60. Heywood, a negro porter at the railroad depot, was ordered by Brown's followers to join them. He refused, and attempting to escape was shot dead. The citizens had by this time begun to recover from the stupor into which the audacity of Brown's attack had plunged them. A desultory firing was opened upon the arsenal, and several persons were killed and wounded upon either side, including the mayor and two other prominent citizens, and one of Brown's sons. But until noon Brown virtually held possession of the town. Up to that time his force had been increased only by the accession of six or eight negroes, who were compelled by threats to join him. As the day advanced, opposing forces gathered around him. Militia from the neighborhood marched into the town, and the captors of the arsenal soon found themselves closely besieged in the building. Of the two insurgents guarding the bridge, one was killed and one captured. Five men who occupied the rifle works were driven out, and all were either killed or captured. The arsenal was now commanded on all sides by the armed Virginians, who poured ceaseless volleys upon it, which were returned by the garrison. So greatly were the attacking forces incensed by the shooting of the mayor and other popular citizens that when Aaron D. Stevens, one of Brown's most trusted followers, was sent out with a flag of truce, he was instantly shot down, receiving six balls in his body; and Thompson, the prisoner captured at the bridge, was put to death. By nightfall of the 17th the arsenal was completely invested by the militia, and Brown retired, with such of his prisoners as had not escaped, to the engine house, an attack upon which he repulsed with a loss of two killed and six wounded to the assailants. Soon after this the firing ceased for the day. The situation was then desperate for Brown. His force had dwindled to three uninjured white men besides himself, and a few negroes from the neighborhood. The remainder were killed or mortally wounded, with the exception of half a dozen who had been sent out in the morning to liberate slaves and could not rejoin their chief. The latter nevertheless displayed

during the night a coolness and self-control which extorted the admiration of his prisoners. "With one son dead by his side," says Col. Washington, "and another shot through, he felt the pulse of his dying son with one hand, held his rifle in the other, and commanded his men with the utmost composure, encouraging them to be firm and to sell their lives as dearly as possible." An offer to release his prisoners provided his men were permitted to cross the bridge in safety having been rejected, the last avenue of escape was closed to him. During the night Col. Robert E. Lee, with a body of United States marines and two pieces of artillery, arrived and took post near the engine house. At 7 o'clock on the morning of the 18th these troops battered in the door of the building, and in an instant overpowered the small garrison. Brown, fighting desperately to the last, was struck down by a sabre stroke, and while prostrate on the ground was twice bayoneted. Although grievously wounded, he preserved his undaunted bearing. When questioned as to his object in seizing the arsenal and imprisoning citizens, he answered with perfect frankness, but refused to compromise persons still at liberty. Gov. Wise and Senator Mason of Virginia, and Mr. C. L. Valandigham, a member of congress from Ohio, cross-examined him closely, but failed to elicit any other than a simple statement of his motives and personal acts. He declined to answer no reasonable question, asserting that he had only done his duty in attempting to liberate the slaves of Virginia, and that he had nothing to regret save the failure of the enterprise. He however expressed great solicitude for his son Watson, who was captured in a dying condition, and who died on Wednesday, the 19th. On the same day Brown and his three surviving comrades were conveyed to the jail in Charlestown, Va. They were indicted a few days later for conspiring with negroes to produce insurrection, for treason against the commonwealth of Virginia, and for murder. On Oct. 27 Brown was brought to trial, his request for a brief delay on the ground that he was mentally and physically unable to proceed with his trial, and that he wished to confer with counsel of his own choice instead of those assigned to him by the court, having been denied. He was laid upon a cot within the bar, being too feeble to stand or even to sit, and, in the presence of a court and jury violently prejudiced against him, conducted himself with singular calmness. He repelled with indignation the plea of insanity attempted to be urged in his behalf, and even offered, in order to save time and trouble, to identify papers in his own handwriting which afforded strong evidence against him. Counsel meanwhile arrived from the north to defend him, and the trial went on. On the 31st he was found guilty on all the counts in the indictment, and on the succeeding day he was sentenced to be hanged on Dec. 2. In the speech

which he addressed to the court on this occasion he disavowed any intention of committing murder or treason or the wilful destruction of property. His prime object, he said, was to liberate the slaves, not to excite them to insurrection, and he therefore felt no consciousness of guilt. He laid considerable stress on his kind treatment of his prisoners in the arsenal, and also expressed himself satisfied with the treatment he had himself received on the trial. During his imprisonment he received visits from his wife and a number of northern friends, and held arguments on the slavery question with southern clergymen who attempted to offer him the consolations of religion. On the day appointed for his execution he left the jail, an eye-witness said, "with a radiant countenance and the step of a conqueror," pausing for a moment by the door to kiss a negro child held up to him by its mother. On the scaffold he was calm, gentle, and resigned, and warmly thanked all who had been kind to him during his imprisonment. Noticing that none but troops were present at the place of execution, he remarked that citizens should not have been denied the privilege of coming to see him die. He met his death with perfect composure, and was apparently the least concerned of all present over the tragic event of the day. His body was delivered to his widow at Harper's Ferry, by whom it was conveyed to the farm in North Elba to be interred. John Brown died as he had lived, a resolute, unyielding zealot. His piety was as sincere as it was severe. On one occasion in Kansas he compelled a party of profane Missourians captured by him to kneel and pray under penalty of being shot; and during the few weeks preceding the capture of the arsenal at Harper's Ferry he caused his followers to engage daily in prayer and the reading of the Scriptures. On every subject but slavery he was shrewd and eminently practical. As an exponent of the austere virtues of the men who founded the New England colonies, he seemed an offshoot from an earlier age; and it would be difficult to find his counterpart in that regard among men prominent in American history during the past half century.

BROWN, John Newton, D. D., an American clergyman and author, born in New London, Conn., June 29, 1803, died in Germantown, Penn., May 15, 1868. He studied at the literary and theological institution, now Madison university, Hamilton, N. Y., and entered upon his duties as a preacher in Buffalo, N. Y., where he remained one year. He then removed to Providence, R. I., to assist the Rev. Dr. Gano, pastor of the first Baptist church in that city, and afterward preached at Malden, Mass., and in Exeter, N. H. At Exeter he edited the "Encyclopædia of Religious Knowledge" (1 vol. small 4to, Brattleboro, 1835), which was republished in England. In 1838 he became professor of exegetical theology and ecclesiastical history in the New Hampton theological

institution, N. H. In 1845 his health compelled him to remove south, and he became pastor of a church in Lexington, Va., where he remained till 1849. He then removed to Pennsylvania, and was appointed editorial secretary of the American Baptist publication society. He was also editor of the "Christian Chronicle" and the "National Baptist." At the time of his death he was engaged upon a history of the Baptist denomination.

BROWN, Nicholas, the principal patron of Brown university, born in Providence, R. I., April 4, 1769, died Oct. 27, 1841. He was liberally educated at the Rhode Island college, at the age of 22 inherited an ample fortune, and founded the mercantile house of Brown and Ives, one of the most successful in the country. In 1796 he was chosen secretary of Rhode Island college, which office he retained till 1825, when he was elected to the board of fellows. When first made secretary he presented the college with \$5,000 and a good law library, in consequence of which the name of the college was changed to that of Brown university. In 1823 he built a second college edifice entirely at his own expense. His gifts to the university amounted in all to \$100,000. He also contributed largely to the Providence Athenæum, and aided in the building of churches and the endowment of colleges in every part of the country. He bequeathed \$30,000 for the establishment of an insane asylum at Providence.

BROWN, Robert, an English Puritan theologian, founder of the sect of Brownists, born about 1550, died about 1630. His family was nearly connected with Cecil, afterward Lord Burleigh. He studied at Corpus Christi college, Cambridge, where he first imbibed his Puritan beliefs from Thomas Cartwright, then professor of divinity. Cartwright's views were, however, only the germs of the opinions soon developed by Brown, who on leaving Cambridge at once began a vigorous opposition to the whole discipline and liturgy of the established church. Acting as a schoolmaster, lecturer, and preacher at Islington, he nevertheless devoted much of his time to excursions about the country, delivering polemical addresses. For the agitation thus created he was for a short time imprisoned by the bishop of Norwich in 1580 or 1581; but on acknowledging that he had employed wrong means in the propagation of his theories, he was released. He next became pastor of a Dutch society of Anabaptists at Norwich, and made many converts to his doctrines. The virulence of his attacks on the Anglican hierarchy caused him to be summoned before an ecclesiastical commission, who again placed him in custody, but Lord Burleigh procured his release. These and other imprisonments, censures, and persecutions caused many to look upon Brown as a martyr for conscience, and he gained a considerable following. But constant interference with his congregation now forced him to leave England, and he and his

followers went to Holland and Zealand, where they established themselves. Their principal congregation was at Middelburg in Zealand; others were at Amsterdam and Leyden. Here they speedily became involved in dissensions with the sects about them, and finally quarrelled among themselves. Brown returned to England in 1585, and after preaching for a time at Norwich as before, and subjecting himself first to admonition by the bishop, and then, by his persistency, to excommunication, he suddenly announced his recantation, and begged for readmission into the established church. This was accorded him in 1590, and he was soon made rector of a small church near Thrapston, Northamptonshire. During the remainder of his life he is said to have been idle and dissolute, seldom entering his church. He died in prison, whither he had been sent for resisting a constable who had demanded his taxes.—The views held by Brown and his followers were briefly these: Every religious congregation should constitute an independent, self-governing body, whose minister should be chosen by it. All members of such a congregation should be equal; and a layman might act as minister, or question the minister. There should be no fixed forms of prayer, but this should be extempore. Marriage should not be celebrated in the churches, but considered as a civil contract. The Brownists also desired change in many minor points. Brown's followers maintained these principles after his defection, and rapidly grew into the large and influential sect of Independents. Brown's principal writings are: "A Treatise of Reformation, without tarrying for any Man;" "A Treatise on the Trinity, third chapter of St. Matthew," &c.; and "A Book which sheweth the Life and Manners of all True Christians." These were published together at Middelburg in 1582.

BROWN, Robert, a British botanist, born at Montrose, Dec. 21, 1773, died in London, June 10, 1858. He studied medicine at Edinburgh, and was appointed botanist in the Australian expedition of Capt. Flinders, which sailed in July, 1801. Accompanied by the flower painter Frederick Bauer, he visited the coasts of Australia, Tasmania, and many of the islands of Bass's strait, returning to England in 1805 with a rich collection of plants, comprising more than 4,000 different species. He was then appointed conservator of the botanical collections of Sir Joseph Banks and librarian of the Linnaean society, and labored several years at the methodical arrangement of the numerous species of plants collected in New Holland. An outline of this labor was published in 1810, under the title of *Prodromus Floræ Novæ Hollandiæ*. In 1814 he published his "General Remarks on the Botany of Terra Australis," as an appendix to Flinders's narrative, and in 1830 a *Supplementum primum Floræ Novæ Hollandiæ*. He also described and classified the different species of plants collected, be-

tween 1802 and 1815, by Horsfield in Java, and those collected by Salt in Abyssinia, by Oudney and Clapperton in the interior of Africa, and by Christian Smith at the mouth of the Congo. He was appointed in 1827 keeper of the botanical department of the British museum, and retained that position until his death. Brown was the first English botanist to make an extensive application of the natural system of Jussieu. Vegetable physiology is indebted to him for several important discoveries. He first spoke of the peculiar movement of the molecules of pollen in plants, which is known by his name; and was the first to demonstrate that these molecules, on quitting the anthers, penetrate through the style down to the ovule below. On the death of Bishop Stanley in 1849, he was elected president of the Linnæan society. Humboldt styles him "the greatest botanist of our age."

BROWN, Sir Samuel, an English engineer, born in London in 1776, died March 15, 1852. He entered the navy at the age of 18, was made commander in 1811, and retired as captain in 1842. He brought into use both chain cables and iron suspension bridges, making the chains of long bars of flat or round iron pinned together by short links and bolt pins.

BROWN, Samuel, a Scottish chemist and poet, born at Haddington, Feb. 23, 1817, died in Edinburgh, Sept. 20, 1856. In 1832 he entered the university of Edinburgh, devoting himself chiefly to chemical studies. He began his public career in 1840 by delivering a course of lectures on the philosophy of the sciences. He early became interested in the nature of atoms and the laws of atomic action, contending that chemical substances usually considered simple are transmutable into each other. In 1843, believing that he was prepared to prove the isomerism and transmutability of carbon and silicon, he became a candidate for the chair of chemistry in the university of Edinburgh; but upon finding his proof incomplete, he withdrew. Subsequently he occupied himself with constant experiments upon his favorite subject, and at his death believed that he was on the point of a complete demonstration. In 1849 he delivered in Edinburgh a series of lectures on the history of chemistry, and in 1850 appeared his "Tragedy of Galileo." Two volumes of his essays and lectures were published in 1858, entitled "Lectures on the Atomic Theory, and Essays Scientific and Literary."

BROWN, Tarleton, an American soldier, born in Barnwell district, S. C., in 1754, died in 1846. He served throughout the revolutionary war, obtained the rank of captain, and left interesting "Memoirs" of his experience, containing much original information concerning the events of the time in the two Carolinas (privately printed, New York, 1862).

BROWN, Thomas, commonly called "Tom," an English satirist, born in Shropshire in 1663, died in 1704. He was educated at Oxford, became for a short time master of the

free school at Kingston-upon-Thames, and was for the rest of his life a "Grub street writer," indolent and fond of low society. He wrote a great deal in prose and verse, chiefly satirical and personal pieces. The highest as well as the lowest characters were the objects of his satire, which is sharp, though coarse and indecent. His first pamphlet, "The Reason of Mr. Bayes changing his Religion," published in 1688, was a personal attack on Dryden, who had become a convert to the Roman Catholic faith a little before. He also wrote "Short Epistles out of Roman, Greek, and French Authors" (1682), and "The Salamanca Wedding" (1693). An edition of his works in three volumes appeared in 1707-'8.

BROWN, Thomas, a Scottish philosopher, born at Kirknabreck, near Dumfries, Jan. 9, 1778, died at Brompton, near London, April 20, 1820. He was educated with great care by his mother. In his 15th year he was presented by Dr. Currie, the biographer of Burns, with the recently published first volume of Dugald Stewart's work on the philosophy of the human mind, which he read with admiration, though he criticised it with acuteness; and the next winter, while attending Stewart's lectures, he made known to the philosopher an objection to one of his theories—a circumstance that led to a lifelong friendship between them. Brown studied and practised medicine, and divided his leisure between the pursuits of poetry and philosophy. He published in 1798 his "Observations on the Zoönomia of Dr. Darwin," which contains the germ of his theory of causation and of the principles by which he was guided in his later philosophical inquiries. He contributed several articles to the early numbers of the "Edinburgh Review," one of which was on the "Philosophy of Kant," a subject of which, however, he had little knowledge. In 1803 he published a collection of his poems in two volumes, many of which had been written while in college, and which exhibited rather a taste than a talent for poetry. A local controversy induced him to publish a defence of Hume's theory of the relation between cause and effect. This work was pronounced by Mackintosh the finest model of philosophical discussion since Berkeley and Hume. It was enlarged in subsequent editions, and published in 1818 under the title of "An Inquiry into the Relation of Cause and Effect." In 1808-'9 he lectured on moral philosophy in the university of Edinburgh during the temporary absence of Stewart, at whose request he was in 1810 appointed adjunct professor of moral philosophy. As a philosopher he was in general opposed to the theories of Reid and Stewart. During the later years of his life he published "The Paradise of Coquettes," and several other poems, but they added nothing to his reputation, which rests chiefly upon his "Lectures on the Philosophy of the Human Mind," first published after his death (4 vols. 8vo, Edinburgh, 1820), and several times republished.

BROWN, William Laurence, a Scottish theologian, born at Utrecht, Holland, where his father was pastor, Jan. 7, 1755, died May 11, 1830. His father returned to Scotland in 1757, and he was sent to the grammar school and university of St. Andrews, but afterward removed to the university of Utrecht, where he combined with the study of divinity that of civil law. In 1778 he became pastor of the English church in that city. Between 1783 and 1793 he took several prizes offered for public competition by different learned bodies in Holland, producing among others a disputation in Latin on the "Origin of Evil," and one on the "Natural Equality of Man," which was printed in Edinburgh in 1793. He was also made professor and then regent of the university of Utrecht. In 1795, upon the approach of the French armies, he fled to England, where he was warmly received, and was made principal of Marischal college, Aberdeen, Scotland. At the first competition for the Burnet prize, his essay on the "Existence of a Supreme Creator" obtained the first place (Aberdeen, 1816). He afterward wrote "A Comparative View of Christianity and of the other Forms of Religion which have existed and still exist in the World, particularly with regard to their Moral Tendency" (Edinburgh, 1826).

BROWN COAL, one of the three great families into which coals are divided by mineralogists, and which are again subdivided into many subordinate varieties. In England it is also called Bovey coal, from Bovey, near Exeter, where it is principally found. The German deposits of brown coal are mainly in Prussian Hesse, Thuringia, the valley of the Rhine, the Westerwald (a hill chain in northern Nassau), and in Saxony. The mineral is also found in Alsace. Vegetable matters are met with in various stages of their conversion into mineral coal. In the formations of the present period they are found in great collections of peat, which are sometimes seen in beds alternating with others of sand and of clay. In the tertiary strata these vegetable collections occur in beds interstratified with others of limestone and the various rocks of this period. In some instances the plants are little altered, so that the species are easily recognized by the structure of the leaves and fruit. The stems are flattened and cross each other in all directions. The woody fibre has become more or less impregnated with bitumen, so that it burns with the peculiar smoke and flame of that substance. This material is called lignite, and sometimes brown coal. Beds of it are worked for fuel in upper Hesse. Another variety of brown coal is more altered in structure, so that its vegetable character is more indistinct, the beds presenting stratified bodies of dark, nearly black substance, with an earthy fracture. The lignite is sometimes seen mixed in the same specimen. This variety of brown coal is worked in the vicinity of Cassel. These varieties make but a poor quality of fuel, often containing from 30

to 48 per cent. of water. A large proportion of this, however, may be expelled by drying, though even then 8 per cent. or more may be reabsorbed. The amount of ash varies in the different qualities from less than 1 to more than 50 per cent. Sulphates of lime, potash, and iron often occur as impurities, and nitrogen is sometimes met with to the extent of 15 per cent. In 21 different analyses of brown coal by different chemists, the proportion of carbon is found to vary from 50 to 70 per cent. Brown coal has been found on both sides of the Andes in South America, and in numerous deposits on the eastern and western slopes of the Rocky mountains.—Jet is a black variety of brown coal, compact in texture, and taking a good polish, whence its use in jewelry. The oil extracted from brown coal, *oleum ligni fossilis*, is used for medicinal purposes. (See COAL.)

BROWNE, Charles Farrar, an American humorist, born at Waterford, Me., April 26, 1834, died at Southampton, England, March 6, 1867. He became a printer, and worked at his trade in Maine, in Boston, and finally in Cincinnati, where he became reporter for a weekly newspaper. In 1858 he wrote for the paper a letter purporting to come from a travelling showman, signing it with the *nom de plume* of Artemus Ward, which he afterward made so well known. In 1860 he went to New York, and became editor of "Vanity Fair," a humorous publication; after the failure of which he turned his attention to lecturing, his first lecture being delivered Dec. 28, 1861. His lectures were humorous in form, and their effect was enhanced by his quaint manner of delivery. In 1862 he published his first book, "Artemus Ward: His Book," which was followed by three other volumes, in 1865, '66, '67. In 1866 he went to England, where he lectured with success, and became a contributor to "Punch." He died there of consumption.

BROWNE, Edward Harold, D. D., an English bishop, born in 1811. He was educated at Cambridge, where he became fellow and tutor in 1835; was incumbent of St. James's, Exeter, in 1841; vice principal and professor of Hebrew at St. David's college, Lampeter, from 1843 to 1849; vicar of Kenwyn and prebendary of Exeter in 1853; Norrisian professor of divinity at Cambridge in 1854; and canon residentiary of Exeter cathedral in 1857. In 1864 he was consecrated bishop of Ely. He is the author of "An Exposition of the Thirty-Nine Articles" (1850; 9th ed., 1871), republished and edited by Bishop Williams of Connecticut. He has also published volumes of sermons, and was one of the contributors to "Aids to Faith," Smith's "Dictionary of the Bible," "The Speaker's Commentary," &c.

BROWNE, Frances, an Irish poetess, born at Stranorlar, county Donegal, June 16, 1818. At the age of 18 months she lost her sight from smallpox, and as she grew up her brothers and sisters read to her such books as they could procure. From the age of 7 to 15 she was

constantly composing verses; but becoming acquainted with the poetry of Pope and Byron, she perceived her own inferiority and for some years abandoned verse-making. In 1841 she began to contribute to the "Athenæum," the editor of which became interested in her story, and introduced her to other periodicals. In 1844 she published a small volume, "The Star of Atteghai, and other Poems," which was well received, and procured for her a pension of £20 from Sir Robert Peel, then prime minister, to whom she dedicated her next volume, the "Legends of Ulster." In 1847 appeared her "Lyric and Miscellaneous Poems," and about the same time a prose story, "The Ericksons." In 1847 she removed to Edinburgh, accompanied by a sister, who acted as her amanuensis, and in 1852 took up her residence in London. She has been a frequent contributor to various periodicals. In 1861 she published "My Share of the World," partially an autobiography, and in 1864 a novel entitled "The Hidden Sin."

BROWNE, George, count, a Russian general, born in Ireland, June 15, 1698, died at Riga, Sept. 18, 1792. He gained much distinction in the Russian service, in which he was actively engaged from 1730 to 1762. He was successively taken prisoner by the Turks and the Prussians, and afterward appointed by Peter III. to command the army against Denmark, with the rank of field marshal. Browne, however, declined taking a part in this war, which he deemed unjust, and the czar at first deprived him of his dignities and ordered him to leave the country, but soon recalled him as governor of Livonia, which office he held under his successor, Catharine II., for 30 years. The title of count was conferred on him in 1779 by the emperor of Germany, Joseph II.

BROWNE, Henriette (the pseudonyme of SOPHIE DE BOUTELLER, Madame Desaulx), a French artist, born in Paris in 1829. She is the great-granddaughter of the Irish general Browne, who settled in France after the battle of Culloden (1746), and the daughter of the count de Bouteiller, a Breton nobleman of much musical and administrative talent, by his marriage with the widow of the Italian composer Benincori. In 1855 she married M. Jules Desaulx, a diplomatist. Her first picture, "Reading the Bible" (1853), has been followed by many other genre paintings, portraits, and etchings, which are popular in England as well as in France. Among her productions are "The Puritans," "Consolation," "The Woman of Eleusis," two interiors of harems, "A Court at Damascus," and "Nubian Dancers."

BROWNE, Isaac Hawkins, an English poet, born at Burton-on-Trent in 1706, died in 1760. Among a collection of poems which he published, a short one called "The Pipe of Tobacco" obtained great popularity. He entered parliament for a Shropshire borough in 1744, but he was too timid to speak in the house. His reputation mainly rests on his Latin poem,

De Animi Immortalitate, modelled on the style of Lucretius and Virgil (1754).

BROWNE, John Ross, an American traveller and author, born in Ireland in 1817. While he was a child his father emigrated to America and settled in Kentucky. Young Browne, having learned stenography, went to Washington in his 18th year, and for two or three years was employed as a reporter in the senate. He then resolved to travel, and embarked on board a whaling ship. Returning from this voyage, he published "Etchings of a Whaling Cruise, with Notes of a Residence on the Island of Zanzibar." He now became private secretary to Mr. R. J. Walker, then secretary of the treasury. In 1849 he went to California with a commission from the government, and was employed to report the debates and proceedings of the convention for framing a state constitution. Returning to Washington, he remained there till 1851, when he went to Europe as a newspaper correspondent. He travelled through Italy, and made a tour in Sicily, and thence through Palestine, of which he gave an account in his "Yusef" (1853). Returning, he again entered the service of government as inspector of custom houses on the northern frontier and the Pacific coast, and wrote many magazine articles, some of which have since been collected into a volume entitled "Adventures in the Apache Country." In 1861 he again went to Europe, partly for the education of his children. Leaving his family at Frankfort-on-the-Main, he made journeys in Algeria, Iceland, Poland, and Russia. Accounts of some of these excursions have been published in volumes entitled "The Land of Thor" and "An American Family in Germany." All of these works are illustrated by sketches, mainly of a humorous character, from drawings by the author. Returning to the United States, he was deputed by government to examine into and report upon the mineral resources of the region west of the Rocky mountains. His final report, "Resources of the Pacific Slope" (8vo, New York, 1869), presents an elaborate review of the mines, climate, topography, agriculture, commerce, and miscellaneous resources of that portion of the Union. In 1868 he was appointed minister to China, but was recalled in 1870. His residence is at Oakland, near San Francisco.

BROWNE, Mary Ann (Mrs. JAMES GRAY), an English poetess, born at Maidenhead Thicket, Berkshire, Sept. 24, 1812, died in Cork, Jan. 28, 1846. Her first volume, "Mont Blanc and other Poems," was published before she was 15. Her second volume, "Ada," appeared in 1828. "Repentance and other Poems" (chiefly of a religious character) followed in 1829. The "Coronal" and "Birthday Gift" were published in 1833 and 1834. "Ignatia," her longest and most finished work, was published in 1838. She wrote for the "Dublin University Magazine" a series of prose tales entitled "Recollections of a Portrait Painter," and a num-

ber of poems, afterward collected as "Sketches from the Antique" (1844). About the same time a volume of "Sacred Poems" appeared. In 1842 she was married to Mr. James Gray, a nephew of the Ettrick Shepherd.

BROWNE, Simon, an English theologian, born at Shepton-Mallet, Somersetshire, in 1680, died in 1732. He was pastor of dissenting congregations in Portsmouth and London. In 1723, after the sudden death of his wife and only son, he conceived that the Almighty had taken away from him his rational soul, resigned his pastoral office, withdrew to his native town, and refused all society. Yet it was during this retirement that he published his principal works, which were directed against the opinions of Woolston and Tindal, and which display learning and a vigorous understanding.

BROWNE, Sir Thomas, an English physician and author, born in London, Oct. 19, 1605, died at Norwich, Oct. 19, 1682. After studying at Oxford he took his degree at Leyden, returned to England, and in 1636 established himself at Norwich. His first work, *Religio Medici*, appeared in 1642. It was a sort of confession of faith, remarkable for its quaint and original fancy, was soon translated into Latin and several continental languages, and gave him a wide reputation. This was followed in 1646 by his "*Pseudodoxia Epidemica*, or Inquiry into Vulgar Errors," the learning displayed in which is such that it has been called a cyclopædia of contemporary knowledge. Subsequently appeared his "*Hydriotaphia*, Urn Burial, or Discourse on Sepulchral Urns." His style abounds in felicitous expressions, but in his eagerness for brevity he often becomes obscure, and no other writer has so freely formed English words from the Latin. His "Christian Morals," a posthumous work, appeared first in 1716, and afterward, with a life of the author by Dr. Johnson, in 1756. His collected works, first published in folio in 1686, were edited by Wilkin (4 vols. 8vo, 1886), and reprinted in Bohn's "Antiquarian Library" (3 vols.).

BROWNE, William, an English poet, born at Tavistock, Devonshire, in 1590, died about 1645. He was educated at Oxford, and was afterward tutor successively to the earls of Carnarvon and of Pembroke. His principal poetical works are entitled "Britannia's Pastorals" (1613-'16), and the Shepherd's Pipe" (1614). They contain some fine descriptive passages, and were admired by Selden and Ben Jonson.

BROWNE, William George, an English traveller, born in London in 1768, died in Persia in 1813. He was educated at Oxford, travelled in Egypt, and attempted to explore the interior of Africa, but was stopped in Darfoor, where he was detained as a captive for three years. He published "Travels in Africa, Egypt, and Syria, in the years 1792-'98" (London, 1799; 2d ed. enlarged, 1806). He afterward undertook a journey through Persia, but on the way from Tabriz to Teheran was murdered by banditti.

BROWNELL, Henry Howard, an American author, born in Providence, R. I., Feb. 6, 1820, died in East Hartford, Conn., Oct. 31, 1872. He graduated at Washington (Trinity) college, Hartford, in 1841, and subsequently studied law, and was admitted to the bar, but turned his attention more especially to teaching and to authorship. A volume of his "Poems" was published in New York in 1847. He afterward wrote "The People's Book of Ancient and Modern History" (Hartford, 1851), and "The Discoverers, Pioneers, and Settlers of North and South America" (Boston, 1853). In the latter part of 1863 he entered the navy, and served as an acting ensign on the staff of Admiral Farragut. During the war he published several spirited and popular poems, which were gathered in a volume entitled "Lyrics of a Day, or Newspaper Poetry, by a Volunteer in the U. S. Service" (New York, 1864). After the war he accompanied Admiral Farragut to Europe, and then resigned and returned to Hartford. In 1866 a volume of his "War Lyrics and other Poems" was published in Boston.

BROWNELL, Thomas Church, D. D., LL.D., an American clergyman, born at Westport, Mass., Oct. 19, 1779, died in Hartford, Conn., Jan. 13, 1865. He was the son of a farmer, and was educated at Bristol academy, Taunton, at Rhode Island college (now Brown university), and at Union college, where he graduated in 1804. The next year he became tutor in Union college, in 1807 professor of belles-lettres and moral philosophy, and in 1809 was chosen the first professor of chemistry and mineralogy. The following year was spent in travelling through Great Britain and Ireland, and in gathering materials and apparatus for the department under his charge. In 1813 he began to turn his attention to preparation for the ministry, and having become an Episcopalian was ordained by Bishop Hobart, in Trinity church, New York, April 11, 1816. In connection with his professional duties he gave himself to the work of a missionary in Schenectady and its vicinity. In the summer of 1818 he became an assistant minister in Trinity church, New York. He was consecrated bishop of Connecticut Oct. 27, 1819, and removed at once to his new field of labor. Washington (now Trinity) college, at Hartford, Conn., took its rise under his auspices in 1824; he was its first president, resigning in 1831. He became presiding bishop in 1852, upon the death of Bishop Chase of Illinois. He was author of "The Family Prayer Book," which contains a commentary, historical, explanatory, doctrinal, and practical, on the liturgy of the Episcopal church. In 1839-'40 he prepared the "Religion of the Heart and Life" (5 vols. 12mo), a compilation from the best writers on experimental and practical piety, with introductions, &c.

BROWNING, Elizabeth Barrett, an English poetess, born at Hope End, near Ledbury, Herefordshire, in 1809, died in Florence, Italy, June

29, 1861. She was educated with great care in a masculine range of studies, and with a masculine strictness of intellectual discipline. She began to write at a very early age for periodical publications. In 1826 she published a volume entitled "An Essay on Mind, with other Poems." No portion of this volume is included in her collected poems. In 1833 appeared "Prometheus Bound, and Miscellaneous Poems." Her version of the "Prometheus Bound" cannot be considered successful, and she subsequently pronounced it an "early failure," and replaced it by a new translation. Some of the smaller poems in this volume are marked by the characteristics of her most mature productions. In 1838 she published a volume entitled "The Seraphim, and other Poems," of which the principal is a lyrical drama, embodying the thoughts and emotions which may be supposed to be awakened in angelic natures by the spectacle of the crucifixion. This production, as well as her "Drama of Exile," a subsequent work, in which the theme is drawn from the fall of man, is a very bold but not very successful effort to soar into heights of speculation and invention. In some of the smaller poems contained in this last mentioned volume, such as "Isobel's Child," "My Doves," and "The Sleep," we have glimpses of all that her genius was destined to accomplish. About the time of the publication of this volume her health, which had always been delicate, was seriously impaired by the rupture of a blood vessel, and for a long time she was on the verge between life and death. Her existence for many years was that of a confirmed and seemingly hopeless invalid. She did not leave her room, and saw only the members of her family and a few intimate friends. The long hours of illness were soothed by composition and study. The poets and philosophers of Greece were the companions of her mind, and some of the inspired writers of the Old Testament were studied by her in their original language. Some of the fruits of these studies were made public in a series of articles on the Greek Christian poets, which appeared in the London "Athenæum." In 1844 the first collected edition of her poems appeared in two volumes. In this her earlier productions were revised, and many pieces appeared for the first time in print, including "Lady Geraldine's Courtship," one of the most beautiful of her poems. It contained a graceful compliment to Mr. Browning, to whom she had not previously been personally known. That poet called to express in person his acknowledgments, and the acquaintance thus made ripened into intimacy and finally into love. Her health improved, and she became the wife of Robert Browning in the autumn of 1846. The growth and progress of this new feeling, and its effects upon her heart and mind, are described with rare grace of expression, as well as exquisite depth and tenderness of feeling, in a series of poems called "Sonnets

from the Portuguese," which appeared for the first time in the second edition of her collected poems, published in 1850. After their marriage Mr. and Mrs. Browning resided for many years in Florence. In 1851 she published "Casa Guidi Windows," a poem on some of the social and political aspects of Italy, the title of which is taken from the name of the house in which she lived in Florence. In 1856 she published "Aurora Leigh," a narrative poem in nine books; a sort of versified novel, of which the subject, characters, and incidents are taken from English life and manners of the present day. Her last publication, entitled "Poems before Congress," appeared in 1860. Mrs. Browning's rank among English poets is very high, and among female poets she holds unquestionably the first place. She combined in an extraordinary degree the distinctive characteristics of the masculine understanding and the feminine heart. She considered carefully, and was capable of treating wisely, the deepest social problems which have engaged the attention of the most sagacious and practical minds, and yet no one has ever given truer and more fervid expression to the joys, the sorrows, the aspirations, and the visions of the purely womanly nature.

BROWNING, Robert, an English poet, born in Camberwell, a suburb of London, in 1812. He was educated at the London university. At the age of 20 he went to Italy, where he remained some years, in order to make himself familiar with all that was peculiarly Italian. The mediæval history of that country, so fruitful in records of fervid passion and startling crime, was studied in its abundant chronicles and local memoirs. He spent much time in the monasteries of Lombardy and Venice, exploring their dusty libraries, and in the silent air of monastic life, calling up a more distinct image of the past than could have been vouchsafed to him in any "bustle of resort." But he devoted himself with equal energy to the task of making himself acquainted with the life and characteristics of the people around him. He studied a class of Italian population of which most travellers have only occasional glimpses—the peasants in their rural homes, and the residents of those dreamy old towns in which life flows on with so quiet a current. No traveller ever brought away a larger intellectual harvest from Italy than Mr. Browning; and the effect of his Italian life is distinctly perceived by the readers of his poetry, alike in his choice of subjects and his treatment of them. In 1835 appeared his "Paracelsus," a dramatic poem in which the principal character was the celebrated empiric and alchemist of the 16th century. It did not attract general attention, and has not the elements which secure popularity; but among the discerning few it was welcomed as the work of a truly original mind, rich in performance, and more rich in promise. In 1837 his tragedy "Strafford" was presented on the stage in London; but in spite of the ad-

mirable acting of Macready, by whom the principal character was sustained, it met with very moderate success. In 1840 he published "Sordello," a poem, the subject of which was drawn from the supposed life of the Mantuan poet, who appears in the 6th canto of Dante's *Purgatorio*. The general public pronounced this work an unintelligible rhapsody, with no meaning at all, and Mr. Browning has judiciously omitted it in the collective edition of his poems. Between 1842 and 1846 there appeared from his pen several successive numbers of a collection of dramatic and lyric poems, to which he gave the title of "Bells and Pomegranates;" an affected designation, and which had the further disadvantage of giving no hint as to the nature of the contents. Among these was a tragedy of striking poetical power, called "A Blot on the Scutcheon," which was produced in Drury Lane theatre in 1843, but without marked success. Another play of his, "The Duchess of Cleves," was subsequently brought out at the Haymarket, Miss Cushman personating the heroine. In 1849 his collective poems were published in London and Boston, which introduced him to a larger circle of readers than he had before enjoyed. In 1850 he published "Christmas Eve and Easter Day," a poem, in which a picture is presented from the author's point of view of some of the religious and spiritual aspects of the age, and some of his own convictions are expressed. In 1855 appeared his "Men and Women," a collection of poems. His latest publications are "The Ring and the Book," "Balaustion's Adventure" (1871), "Prince Hohenstiel-Schwangau, Saviour of Society" (1871), "Fifine at the Fair" (1872), and "Red Cotton Nightcap Country" (1873).—In November, 1846, Mr. Browning was married to Elizabeth Barrett. Soon after her death he returned to England with their only child, a son, and now resides in or near London.

BROWNLOW, William Gannaway, an American clergyman, journalist, and politician, born in Wythe co., Va., Aug. 29, 1805. Left an orphan at an early age, he learned the trade of a carpenter. In 1826 he entered the Methodist ministry, and labored for ten years as an itinerant preacher. As early as 1828 he began to take part in politics in Tennessee, advocating the reelection of John Quincy Adams to the presidency; and while travelling a circuit in South Carolina in which John O. Calhoun lived, he publicly opposed nullification. About 1837 he became editor of the "Knoxville Whig," a political newspaper. In consequence of his trenchant mode of expression, he became known as "the fighting parson." In 1856 he published "The Iron Wheel Examined and its Spokes Extracted," being a reply to attacks made upon the Methodist church. In 1858 he held a public debate in Philadelphia with the Rev. A. Fryne of New York, which was published in a volume entitled "Ought American Slavery to be Perpetuated?" Mr. Brownlow taking the affirmative. When the movement

for secession took place, he advocated the preservation of the Union as the best safeguard for southern institutions. In December, 1861, he was arrested on charge of treason against the confederacy, and detained till March, 1862, when he was sent within the Union lines. After this he made a tour through the northern states, delivering speeches in the principal cities, and published a book entitled "Sketches of the Rise, Progress, and Decline of Secession," &c. In 1864 he returned to Tennessee, of which he became governor in 1865; and in 1869 he was elected to the senate of the United States.

BROWN-SÉQUARD, Charles Edward, a French-American physiologist, born in the island of Mauritius in 1818. His father, Edward Brown, was a native of Philadelphia, and at one time commanded an American merchant vessel. He was lost at sea, in an attempt which he had volunteered in an old and badly found vessel to procure provisions for Mauritius, at that time suffering under famine. His mother, from whom he derives the name Séquard, was a French woman. Young Brown-Séquard was carefully educated in his native island. In 1838 he went to Paris to complete his studies, and received there the degree of M. D. in 1840. Since that time he has devoted his attention mainly to experimental physiology. He has had a prize awarded him five times by the French academy of sciences, and he has twice received a part of the queen's grant for the encouragement of science from the royal society of London. He visited the United States several times, and delivered courses of lectures before various scientific bodies, illustrating his doctrines by the most delicate vivisections. His experiments on the blood give great support to the doctrine that the fibrine of that fluid is an excrementitious product, and not subservient to nutrition. He has produced all the life-giving effects of the natural blood by the transfusion of defibrinated blood. By the injection of oxygenated and defibrinated blood the irritability of the muscles was restored some time after the occurrence of post-mortem rigidity, and the blood returned by the veins venous in color and containing fibrine. Defibrinated and oxygenated, it was again injected by the artery, and thus the same blood was used for hours in maintaining the irritability of the muscles. Arterial blood, according to him, is subservient to nutrition, and maintains the irritability of the muscles; venous blood is necessary to produce muscular contraction. By his experiments on animal heat the temperature in mankind is placed at 103° F., several degrees higher than by previous observers. When animals are asphyxiated their temperature at the time exerts a great influence on the duration of life. Previous observers had noted that certain poisons cause a rapid diminution of the animal temperature; according to Brown-Séquard, when the animal heat is maintained by artificial means, the toxic action is much diminished. The great discovery of Sir Charles Bell of the

respective sensitive and motor functions of the anterior and posterior roots of the spinal cord, directed the attention of physiologists to that subject. After numerous and apparently contradictory experiments, the conclusion was generally acquiesced in that the posterior columns of the cord are sensitive, and convey sensations to the brain; that the anterior are motor, and convey the influence of the will to the voluntary muscles; and that the gray matter of the cord serves merely to reflect impressions from the sensitive to the motor nerve roots. As the result of numerous ingenious experiments, Brown-Séquard concludes that the sensitive fibres do not communicate directly with the brain, but convey impressions to the gray matter of the cord, by which they are transmitted onward to the brain, and that their decussation or crossing takes place in the cord itself, at or near the point at which they enter, not in the cerebrum or medulla oblongata. On the other hand, the anterior or motor fibres pass on directly to the brain, effecting their decussation in the medulla oblongata; the gray matter receives the impressions, conducts them to the brain, or reflects them upon the motor nerves, but is itself insensible to ordinary stimuli. These views enable us to understand some rare and curious facts in pathology which otherwise would remain inexplicable. Other researches of Brown-Séquard relate to the muscles, to the sympathetic system of nerves, to the effect of the removal or destruction of the supra-renal capsules in animals, &c. In May, 1858, he delivered a course of lectures on the nervous system before the royal college of surgeons at London, which attracted much attention. In 1864, having taken up his residence in the United States, he was appointed professor of the physiology and pathology of the nervous system in the medical department of Harvard university, a position which he held till 1868. In 1869, becoming again a resident of France, he was appointed professor of experimental and comparative pathology in the school of medicine at Paris. In 1858 he founded the *Journal de la physiologie de l'homme et des animaux*, which he made from the beginning a leading journal of physiology, and which he continued to conduct as editor till 1868. On his return to France in 1869 he established the *Archives de la physiologie normale et pathologique*, a journal of similar standing with the preceding. He has been a frequent contributor of scientific articles to the journals under his charge, and has also been much engaged as consulting physician for diseases of the nervous system. In 1873 he established himself as a practitioner in New York, and in conjunction with Dr. E. C. Seguin began the publication of a medical journal entitled "Archives of Scientific and Practical Medicine."

BROWNSON, Orestes Augustus, LL. D., an American author, born at Stockbridge, Vt., Sept. 16, 1803. In his 19th year he joined the Presbyterian church at Ballston, N. Y., where he

was at the time attending an academy; but he afterward changed his views, and became in 1825 a Universalist minister. He preached in different villages of Vermont and New York, and wrote for various religious periodicals in support of his new belief. His ecclesiastical position had grown into disfavor with him, when, making the acquaintance of Robert Owen, he was fascinated by schemes of social reform, and in 1828 he was prominent in the formation of the working men's party in New York, the design of which was to relieve the poorer classes by political organization; but he presently despaired of the effectiveness of this movement. Afterward the writings of Dr. Channing drew his attention to the Unitarians, and in 1832 he became pastor of a congregation of that denomination. In 1836 he organized in Boston the "Society for Christian Union and Progress," of which he retained the pastorate till he ceased preaching in 1843. Immediately after removing to Boston he published his "New Views of Christianity, Society, and the Church," remarkable for its protest against Protestantism. In 1838 he established the "Boston Quarterly Review," of which he was proprietor, and almost sole writer, during the five years of its separate existence, and to which he contributed largely during the first year after it was merged in the "Democratic Review" of New York. It was designed not to support any definite doctrine, but to awaken thought on great subjects, with reference to speedy and radical changes. To this end also he published in 1840 "Charles Elwood, or the Infidel Converted," a philosophico-religious treatise, in the form of a novel. In 1844 he entered the Roman Catholic communion, to which he has since remained attached. The method which he adopts in his philosophical system is the distinction between intuition (direct perception) and reflection (indirect or reflex knowledge). The mind is unconsciously intuitive; it does not, in intuition, know that it has intuition of this or that truth, because as soon as it knows or is conscious of the intuition it has reflex knowledge. Reflection can contain nothing which is not first in intuition. In order to reflect on that which we know intuitively, we must have some sensible sign by which the mind may apprehend or take hold of it. Such a sign is language, both in the ordinary and figurative sense of the word, which thus holds in the metaphysics of Mr. Brownson a place corresponding to that which tradition holds in his religious system. The knowledge of God, he maintains, is intuitive. The ideal element of every intellectual act is God creating creatures, *ens creat existentias*. The later publications of Mr. Brownson are "The Spirit Rapper" (1854), "The Convert, or Leaves from my Experience" (1857), and "The American Republic" (1865). From 1844 he supported almost single-handed, in Boston and New York, "Brownson's Quarterly Review," devoted especially to the defence of Roman Cath-

olic doctrines, but also discussing politics and literature. This periodical was suspended in 1864 and revived in 1873. He was invited by Dr. John H. Newman and others to accept a chair in the new university in Dublin, but he preferred to continue his labors in his native country. Translations of several of his works and essays have been published in Europe.

BROWN SPAR, a name given to dolomite, the magnesian carbonate of lime, when this is of a brown or reddish-brown color, from a small percentage of oxide of iron or oxide of manganese. Crystals of spathic iron and the mineral magnesite are sometimes called by the same name.

BROWNSVILLE. I. A post borough of Fayette co., Penn., on the Monongahela river, where it is crossed by the national road, about 80 m. S. of Pittsburgh; pop. in 1870, 1,749. A bridge over the river has been erected here at a cost of \$50,000, and another bridge, of cast iron, over Dunlap's creek, connects Browns-ville with the neighboring borough of Bridgeport. In the vicinity are rich mines of bituminous coal. The Monongahela is navigable to this point for large steamboats. **II.** A city, capital of Cameron co., Texas, on the left bank of the Rio Grande, opposite Matamoros, about 35 m. from the gulf of Mexico, and 310 m. S. of Austin; pop. in 1870, 4,905. It is easily accessible by steamboats, and contains a custom house and several churches. At the commencement of the war with Mexico, in 1846, the United States troops under Gen. Taylor occupied this place, threw up a strong work, and, leaving in it a small garrison, marched to the relief of Point Isabel, on the coast, where their supplies were threatened. In the mean time the Mexicans, under cover of the guns of Matamoros, erected batteries, and on May 4 commenced a bombardment of the fort, which lasted 160 hours. The Americans defended themselves with spirit, maintaining their position until the surrender of the city to Taylor, but losing their commander, Major Brown, who was killed by a shell on the 6th. It is in honor of this officer that the town was named. There is now a fort (Fort Brown) with a garrison of United States troops at this point. **III.** A village, capital of Haywood co., Tenn., on the Memphis and Louisville railroad, 57 m. N. E. of Memphis; pop. in 1870, 2,454, of whom 1,016 were colored. It is situated in the midst of a rich, level country, is surrounded by cotton and maize plantations, and is the centre of an active trade. It contains a female college under the direction of the Baptists.

BROWN UNIVERSITY (formerly Rhode Island College), a seat of learning in Providence, R. I., founded about the middle of the last century by the Philadelphia association of Baptist churches, at the special instigation of the Rev. Morgan Edwards, a Welsh clergyman of Philadelphia. The Rev. James Manning, a native of New Jersey, and graduate of Princeton, was authorized in 1763 to broach the scheme to

certain prominent Baptists of Newport, with whose aid the necessary money was raised, and a charter obtained in February, 1764, "for a college or university in the English colony of Rhode Island and Providence Plantations, in New England, in America." One of the provisions of this charter is as follows: "And furthermore, it is hereby enacted and declared, that into this liberal and catholic institution shall never be admitted any religious tests; but, on the contrary, all the members hereof shall for ever enjoy full, free, absolute, and uninterrupted liberty of conscience; and that the public teaching shall, in general, respect the sciences, and that the sectarian differences of opinions shall not make any part of the public and classical instruction." The government of the college is vested in a board of fellows, consisting of 12 members, of whom 8, including the president, must be Baptists; and a board of trustees, consisting of 36 members, of whom 22 must be Baptists, 5 Friends or Quakers, 4 Congregationalists, and 5 Episcopalians; this proportion representing the different denominations then existing in the colony. The instruction and immediate government of the college rest in the president and board of fellows. In the spring of the year in which the college was established, instruction was commenced at Warren, under the direction of Mr. James Manning, who was formally elected its president in September, 1765. A local contest for the seat of the college was finally terminated in favor of Providence in 1770. During a part of the war of the revolution instruction was suspended, and the college building was occupied by the state militia and by the troops of Rochambeau. Instruction was resumed in 1783. Mr. Manning was elected to congress in 1786, but soon resigned the post in consequence of its incompatibility with his duties to the college, and died in 1791, aged 53. Mr. Manning was succeeded by the Rev. Jonathan Maxcy, who resigned in 1802, and was succeeded by the Rev. Asa Messer, who was president till 1826. In 1804, during his presidency, the college received the name of Brown university, in honor of Nicholas Brown, its most distinguished benefactor. Mr. Messer was succeeded in 1827 by the Rev. Francis Wayland, D. D., who resigned in 1855, having by his personal character and writings greatly extended the reputation and influence of the university. The Rev. Barnas Sears, D. D., LL. D., was then chosen president, and resigned in 1867. He was succeeded by the Rev. Alexis Caswell, D. D., LL. D., and the latter, in January, 1872, by the Rev. E. G. Robinson, D. D., LL. D.—The officers of instruction are the president, nine professors, and three instructors, besides a librarian and register. The university has five college buildings, and a mansion house for the president. Its enclosures are graded and adorned with elms, and comprise upward of 16 acres, situated on high land in the eastern section of the city. The college year is divided into two

terms with two vacations, one of three weeks beginning about the last of January, and another of nine weeks commencing the last week in June. Besides these there are two recesses of a week each. The annual commencement exercises occur on the last Wednesday in June, during which week candidates for admission to the college are examined. The course of study comprises four years. All the studies of the first two years and the first term of the third are compulsory. For the second term of the junior and senior years, geology, political economy, Latin, and Greek are elective; while Latin, Greek, and German are elective studies of the first term of the senior year. In addition to the regular collegiate course, there are courses of study covering three years for the degree of bachelor of philosophy. The annual college expenses are: tuition, \$75; room rent, \$20; use of library, \$3; register's salary, \$4; total, \$102. In the case of indigent students, \$25 per annum on the tuition may be remitted to a number not exceeding two fifths of all the students in college. Scholarships, 57 in number, each yielding about \$60 per annum, have been established; and a fund of \$50,000 has been placed by the state of Rhode Island in the custody of the corporation, the income of which sustains 30 scholarships. The state scholarships are open only to citizens of Rhode Island; and appointments to them are made on the nomination of the general assembly of the state. This fund was realized by the state from the sale of land scrip given by congress for the founding of a college of agriculture, which has been organized in connection with the university. A fund of \$8,000 has been given to the university by two of its friends, the income of which is applied either in the form of a gift or a loan to students. The following departments of practical science have been established in the university: 1, chemistry applied to the arts, in which particular attention is given to metallurgy, pharmacy, medical chemistry, and the application of chemistry to manufacturing processes; and 2, civil engineering, in which the course is three years. The course is not confined to undergraduates in either department. The course in the agricultural and scientific department is three years. The college library contains more than 40,000 volumes, and is constantly increasing from the income of a permanent fund of \$27,000. The museum of natural history contains a valuable collection of specimens. There is also a valuable collection of portraits. The invested funds of the university amount to \$602,653, the greater part having been contributed by private individuals, among whom are John Carter Brown, Nicholas Brown, Alexander Duncan, Rowland G. Hazard, William Sprague, William S. Slater, Earl P. Mason, William H. Reynolds, and H. N. Slater, all residents of Providence; of whom the five last mentioned subscribed in October, 1865, \$20,000 each. The sum of \$50,000 was bequeathed by

the late William Sanford Rogers of Boston, to found "the Newport-Rogers Professorship of Chemistry." According to the last triennial catalogue, issued in 1869, the whole number of alumni was 2,376, of whom 1,351 survived.

BRUCE, a N. W. county of Ontario, Canada, bounded W. by Lake Huron and N. and N. E. by Georgian bay, having a coast line of about 130 m.; area, about 1,600 sq. m.; pop. in 1871, 68,515. The chief river is the Saugeen, flowing N. W. into Lake Huron. The northern part is a rocky peninsula nearly cut off from the rest by Colpoys's bay on the west. The southern portion has a level surface and a good soil. Immense salt beds underlie part of the W. coast, and salt is exported to the United States. Capital, Walkerton.

BRUCE, a noble family of Scotland, three members of which obtained royal dignity. It was descended from Robert de Bruis, a Norman knight, who came to England with William the Conqueror, and whose grandson Robert received the lordship of Annandale from David I. of Scotland. **I. Robert**, fifth lord of Annandale, born in 1210, died at Lochmaben castle in 1295. He was one of the 15 regents of Scotland during the minority of Alexander III. When in 1291, by the death of Margaret, the "maiden of Norway," the succession reverted to the posterity of David, earl of Huntingdon, and youngest brother of King William the Lion, Bruce disputed the succession with John Balliol, the great-grandson of David by his eldest daughter, Margaret, he being the grandson of David by his second daughter, Isobel. The contest was referred to Edward I. of England, who decided "that in all indivisible heritages the more remote in degree of the first line of descent is preferable to the nearest in degree of the second," and thus gave the kingdom to Balliol, from whom he required homage and fealty. Bruce, in order to avoid swearing fealty to Balliol, resigned the lordship of Annandale to his son. **II. Robert**, son of the preceding, lord of Annandale and earl of Carrick, died in 1304. In 1270 he accompanied Edward I. of England to Palestine, and on his return to Scotland married the countess of Carrick, in whose right he became in 1292 earl of Carrick. Following the example of his father, in order to avoid doing homage to Balliol, he resigned the lordship of Annandale to his eldest son Robert, then a minor. Retiring to England, he was in 1295 appointed constable of the castle of Carlisle, and in the following year, when Balliol broke his allegiance to Edward, and, aided by Comyn, took up arms, Bruce fought on the side of the English. After the battle of Dunbar, April 27, 1296, when the Scotch were defeated, and Balliol renounced the sovereignty, Bruce, who was a favorite of Edward, applied to him for the crown of Scotland, but was refused. **III. Robert**, son of the preceding, earl of Carrick, afterward king of Scotland, born March 21, 1274, died June 7, 1329. He acted at first as

Edward's liegeman, but vacillated between the two parties, taking no very active part in the struggle between Wallace and England. He was associated in 1299 with John Comyn, nephew of Balliol and a pretender to the crown, and with the bishop of St. Andrews, as guardians of Scotland. With these he laid a plan for recovering the crown, though apparently still faithful to Edward. This plan was revealed by Comyn, and Bruce, meeting him by appointment at the church of the Minorite friars in Dumfries in 1306, stabbed him in a fit of rage. He then assumed the title of king, summoned the Scots to his standard, and was crowned at Scone in March. Edward made Aymer de Valence, earl of Pembroke, guardian of Scotland, and sent him to chastise the rebels. The force of Bruce was almost immediately destroyed in the wood of Methven; six of his best knights were made prisoners, and he himself was rescued only by the devotion of Seaton. For two months, with his brothers and the ladies of his household, he wandered to and fro in the wilds of the Grampian hills, until his party being discovered and forced to separate, he crossed over to the island of Rathlin, on the north of Ireland. His three brothers, wife, and sister were captured; the brothers were soon after hanged at Carlisle, and the ladies were imprisoned in various parts of England. His estates were confiscated, and he and his adherents were excommunicated by the papal legate. In the spring of 1307 Bruce returned, surprised his own castle of Carrick, defeated small parties of English in many skirmishes, and maintained himself among the hills and forests until Edward marched toward the border. The latter died on his way, leaving to his son a charge not to bury his bones till he had borne them in triumph from Berwick bounds to the utmost highlands. For three years Edward II. paid no attention to the Scottish war, and Bruce in the mean time established his power over nearly all Scotland, and in the spring of 1310 was acknowledged king. In September of the same year Edward marched into Scotland as far as the Forth without encountering an enemy. In the next year he sent Gaveston to renew the war, who penetrated beyond the Forth, but still gained no material advantages. The following years were passed by Edward in contentions with his parliament, and by Bruce in gradually recovering all that he had lost in Scotland, until in 1314 the fortress of Stirling alone held out for the English, and even that the governor, Mowbray, had agreed to surrender if it was not relieved before the feast of St. John the Baptist. This at length aroused Edward, who at the head of a large army encamped in the neighborhood of the beleaguered fortress, and was there met by Bruce with 30,000 picked men, on the eve of the festival fixed for its surrender. The battle of Bannockburn followed, June 24, 1314, and resulted in the utter defeat of the English. Bruce now exchanged his prisoners

against his wife, his sister, and his other relatives, who had been so long in captivity. After this success the Scotch assumed the offensive and invaded Ireland, of which Edward Bruce, brother of Robert, was crowned king in 1316. While the dissensions lasted between Edward and his barons, Robert Bruce repeatedly devastated the borders and all the north of Yorkshire. In 1323 a truce was concluded between the kingdoms for thirteen years. Four years after this Edward II. was compelled to abdicate in favor of his son, Edward III., and Bruce renewed the war, with the avowed intention of forcing Edward to renounce his claim of sovereignty over the crown of Scotland. This renunciation was made by a treaty ratified at Northampton in 1328, by which Scotland was declared sovereign and independent. Bruce's title to the throne was recognized, and Jane of England, the sister of Edward, married to David, prince of Scotland. After his death Bruce's heart was embalmed in accordance with his desire that it should be carried to Palestine and buried in Jerusalem; but James Douglas, who undertook to execute this commission, was killed by the Moors in Spain, and the relic was returned and buried in Melrose abbey. The rest of the body was buried in the abbey church of Dunfermline, where the bones were found in 1818, when the new church was built. In 1872 a statue of Bruce was erected in Stirling castle. Bruce married first Isabella, daughter of Donald, 10th earl of Mar, and had by her a daughter, Marjory, the mother of Robert II.; and second, Elizabeth, daughter of Aymer de Burgh, earl of Ulster, who became the mother of David II., his immediate successor. **IV. David II.**, son of the preceding, king of Scotland, born about 1324, died in Edinburgh castle, Feb. 22, 1371. He was crowned at Scone Nov. 23, 1331, and in the next year was dispossessed by Edward Balliol, son of John Balliol, and forced to take refuge in France, where he resided till 1341, when, Murray, Douglas, and Stuart having expelled Balliol from Scotland, he ventured to return. In 1346, while Edward III. was absent in France, David suddenly invaded England, but was totally defeated by a small army at Neville's Cross in Durham, and taken prisoner. From this time till 1357 David was detained in the tower of London, whence he was liberated after the battle of Poitiers, on the agreement to pay 100,000 marks in 20 half-yearly instalments, a truce being sworn to and hostages interchanged between the two countries. This truce was afterward extended to 25 years further, under the name of the great truce, which was faithfully observed by David's nephew and successor, Robert, the first of the Stuart kings of Scotland. David's wife Jane died in 1362, and he married Margaret Logie, from whom he was divorced in 1369. **V. Edward**, brother of King Robert Bruce, and king of Ireland, was actively engaged in the struggle for the independence of Scotland. In

1808 he defeated the English, and made himself master of Galloway. In 1815 the chieftains of Ulster offered him the crown of Ireland, on condition that he would aid them in expelling the English. He embarked at Ayr with a force of 6,000 men, soon had possession of the whole province of Ulster, and was crowned king May 2, 1816, but was killed at the battle of Dundalk, Oct. 5, 1818.

BRUCE, James, a Scottish traveller, born at Kinnaird, Dec. 14, 1780, died there, April, 27, 1794. He was educated at London, Harrow, and Edinburgh, and intended for the profession of law; but finding the study distasteful, he went to London, where he married the daughter of a wine merchant's widow, and became a partner in the business. In 1757 he made a tour of southern Europe, partly on business and partly for diversion, returning on the death of his father in the following year to take possession of his estate in Scotland. In 1762 he was appointed consul general at Algiers. He had already spent some time in studying the Arabic and other oriental languages, and took great interest in African explorations; and when he reached Algiers in 1763 he made researches into its history and antiquities, besides acquiring some knowledge of surgery and medicine. Superseded in 1765, he travelled through Tunis and Tripoli, examining their historical remains, and finally embarked for Syria. He visited Palmyra and Baalbec, resided for some time in Aleppo, went to Alexandria, and after some researches into the antiquities of Egypt set out to explore the head waters of the Nile. He spent about two years in Abyssinia, and traced the Abai, then supposed to be the main stream of the Nile, to its source. He reached England, after many hardships, in 1774. His "Travels to discover the Sources of the Nile, in the Years 1768-'73," did not appear till 1790 (5 vols. 4to). The work contained many statements which were considered fictions at the time of its appearance, but the truth of which has been confirmed by later travellers. A second edition, accompanied by a biography and copious notes, was prepared in 1805 by Dr. Alexander Murray.

BRUCE, Michael, a Scottish poet, born at Kinrosswood, county of Kinross, March 27, 1746, died there, July 6, 1787. His father was a weaver, but contrived to send him to the university of Edinburgh, to prepare for the ministry. There he struggled with poverty and various discouragements, and became melancholy and consumptive. He finally returned to his native village and died when only 21 years of age, leaving a few poems which were collected and edited by the Rev. John Logan.

BRUCHSAL, a town of Baden, in the circle and 11 m. N. N. E. of Carlsruhe, on the Seilbach, and on the Mannheim and Carlsruhe railroad; pop. in 1871, 9,786. It has a castle which was formerly the residence of the bishop of Spire, a gymnasium, and a hospital of the Brothers of Mercy, with an anatomical museum and an

educational institution. The old castle is now used as a prison, conducted on the Pennsylvania plan.

BRUCIA, a bitter alkaline body, associated with the similar bodies, strychnia and iganuria, in the nux vomica and bean of St. Ignatius. It is crystallizable, soluble in hot and cold water and alcohol, and possesses similar medicinal properties to those of strychnia. As it has only about $\frac{1}{10}$ the strength of strychnia, this is used in preference. It was originally discovered by Pelletier and Caventon in the false *Angostura* bark.

BRUCK, the name of two towns of Austria. **I. Bruck-on-the-Leitha**, in Lower Austria, on the Vienna and Buda railway, 20 m. S. E. of Vienna; pop. in 1869, 4,203. It has a castle of Count Harrach and manufactories of machinery. Near it is a permanent camp of the Austrian army. **II. Bruck-on-the-Mur**, in Styria, on the Vienna and Trieste railway, 25 m. N. by W. of Gratz; pop. about 4,000. Near it is a celebrated cave.

BRÜCKENAU, a town of Bavaria, at the foot of the Rhön, in the valley of the Sinn, 36 m. N. of Würzburg; pop. in 1867, 1,571. It is situated in the midst of beech forests and beautiful mountain scenery, and contains a royal castle. Near the town is a Franciscan convent; and about two miles distant are the chalybeate baths and springs of Brückenau. There are three springs and a few lodging houses, belonging to the king, and under the charge of an inspector.

BRÜCKER, Jakob, a German scholar, born in Augsburg, Jan. 22, 1696, died Nov. 26, 1770. His chief work is the *Historia Critica Philosophia*, from the creation of the world to his own time (5 vols. 4to, Leipsic, 1742-'4), which has been frequently abridged, and freely used by historians of philosophy. He wrote several other philosophical and geographical works.

BRUGES (Flemish, *Brugge*), a city of Belgium, capital of the province of West Flanders, situated about 8 m. from the North sea, with which it is connected by the canals of Ostend, Ghent, and Sluis, and 55 m. N. W. of Brussels; pop. in 1869, 47,621, of whom 15,000 were paupers. It has spacious docks and excellent quays. The shipowners of Bruges are engaged principally in fishing and coasting. Lace is the most important branch of manufacture, and there are also manufactories of linen, cotton, and woollen goods, of soap, leather, tobacco, and porcelain. The town presents a quaint aspect, contains about 200 streets, 9 public squares, 54 bridges (which give it its name), and several beautiful fountains. The church of Notre Dame, with a sculptured Virgin and child, erroneously ascribed to Michel Angelo, and a spire 442 ft. high, the cathedral of St. Saviour, and the hospital of St. John are remarkable for the works of art which they contain. The belfry tower in the great square is 290 ft. high, and its celebrated chimes sound at every hour. The other public buildings are

Belfry of Bruges.

the hôtel de ville, containing a public library, the hall of justice, and the prinsenhof, the ancient palace of the counts of Flanders. Bruges has a flourishing free academy of fine arts, a botanical garden, museum, theatre, an agricultural society, an exchange, a commercial and other tribunals, a gymnasium, and a remarkably large number of charitable institutions. The corporation of weavers of Bruges was celebrated in the

Interior of Town Hall.

time of Charlemagne. From the 9th century till the middle of the 14th the town was under the sway of the counts of Flanders, and reached the height of its prosperity in the 15th century, after having passed under the domin-

ion of the dukes of Burgundy. Factories were established here by merchants from 17 states, and 20 foreign ministers were accredited to its magistrates. In 1430 Philip the Good instituted the order of the golden fleece in honor of the prosperity of the woollen trade of the town. Bruges was then one of the great commercial emporiums of the world, the central mart of the Hanseatic league, and the chief resort for English, Lombard, and Venetian merchants. It had a large share of the commerce of the globe, while its manufactures, especially in tapestry, excelled all others. Hans Memling and the brothers Van Eyck practised their art there. This great prosperity, however, engendered extravagant habits in dress and social life to such an extent that Charles V. was obliged to pass stringent sumptuary laws. The dominion of the house of Hapsburg proved fatal to the prosperity of the town. The citizens, who had always been noted for the jealous care with which they guarded their privileges, imprisoned their first sovereign of that house, the archduke Maximilian, for violating them; and to punish the town the trade was transferred to Antwerp, and its ruin was consummated by the persecutions of the duke of Alva in the latter part of the 16th century, when many of the inhabitants fled to England. The town was on two occasions the asylum of English kings: once when Edward IV. fled from England, and again during the exile of Charles II., the latter inhabiting a house which still stands on the south side of the great square, at the corner of the rue St. Amand, bearing the sign, *Au lion belge*.

BRUGES, Roger van, a Flemish painter, pupil of John van Eyck, flourished about the middle of the 15th century. He was probably the same person as Magister Rogel of Flanders, who painted a "chapel" or altarpiece in three compartments, which was presented by John II. of Castile to the Carthusian church at Miraflores in 1445, and which Charles V. used to carry with him in all his expeditions. He was one of the few artists of his time who painted on canvas.

BRUGG, or Bruck, a village of Switzerland, capital of a district of the same name in the canton of Aargau, on the Aar, 10 m. N. E. of Aarau; pop. in 1870, 1,388. It is surrounded by walls, defended by conical towers, and is built on a portion of the site of the ancient Vindonissa, some remains of which are still to be seen. About 2 m. from the village are the ruins of the ancient castle of the counts of Hapsburg. The ruined abbey of Königsfelden in the same neighborhood was founded in 1310 by the widow and daughter of Albert, emperor of Germany, who was assassinated on the spot. During the reformation Brugg was called the *Prophetenstädtchen*, or the little town of prophets, from the many theologians born there.

BRUGGER, Friedrich, a German sculptor, born in Munich, Jan. 18, 1815, died there, April 9, 1870. He studied at the academy of Munich,

and executed in Rome his first statues of mythological subjects. After his return from Italy in 1843 he was employed by the Bavarian government in commemorating distinguished persons. The mausoleum of the historian Johannes von Müller at Cassel is regarded as one of his masterpieces.

BRUGMANS, Sebaldus Justinus, a Dutch physician and naturalist, born in Franeker, March 24, 1768, died in Leyden, July 22, 1819. The academies of Dijon, Bordeaux, and Berlin awarded prizes to several of his disquisitions on natural history and botany. Becoming professor of philosophy and physical sciences at Franeker, he promoted the study of natural history in the Netherlands, and founded a museum of comparative anatomy which became famous. King Louis Bonaparte attached him to his service, and being appointed professor of botany at Leyden, he also taught there other branches of natural history and chemistry and organized the sanitary institutions of Holland, of which he was made chief director. After the annexation of Holland to France, Napoleon made him rector of the university of Leyden, which he cleared of debt. He especially improved the condition of military hospitals, and it was mainly due to his efforts that relief for over 20,000 wounded soldiers was provided after the battle of Waterloo. In 1815 King William placed him at the head of the sanitary service of the army and navy, and sent him to France to demand the restitution of the collection of natural history which had been taken away during the French domination. He was the chief editor of the *Pharmacopœia Batava*, and published numerous writings on medical science and natural history.

BRUGSCH, Helarich Karl, a German Egyptologist, born in Berlin, Feb. 18, 1827. He early attracted the attention of Alexander von Humboldt and of the king of Prussia by his essays on Egyptology (1848-'50), written while he was at the gymnasium. With their assistance he finished his studies in Berlin. The king defrayed the expenses of his first journey to Egypt (1853). After his return he was appointed director of the Egyptological museum at Berlin. He revisited Egypt in 1857-'8, was the historiographer of the Prussian embassy to Persia in 1860, and after the death of Baron Minutoli was for a time Prussian ambassador to the shah. He founded at Leipzig in 1864 a periodical for Egyptian archæology, which he continued with the assistance of Lepsius during his residence as consul at Cairo (1864-'8). He was professor at Göttingen from 1868 to 1870, when he became director of the Egyptological school at Cairo. His *Hieroglyphisch-demotisches Wörterbuch* (4 vols., Leipzig, 1867-'9) is one of the great sources of information on ancient Egypt. Among his other works are: *Reiseberichte aus Aegypten* (1855); *Recueil de monuments égyptiens* (Leipzig, 1862 et seq.); *Geographische Inschriften alter ägyptischer Denkmäler* (2 vols., 1865-'6); *Die ägyptische*

Gräberwelt (1867); and *Die Sage von der geflügelten Sonnenscheibe* (Berlin, 1870).

BRÜHL, Heinrich, count, a German statesman, born at Weissenfels in 1700, died at Dresden, Oct. 28, 1768. Beginning life as a page, he gained rapid promotion until in 1738 he was enabled to secure the crown of Poland for the elector Augustus II. of Saxony. He became prime minister in 1747; but by humoring the costly caprices of the king, and by his own extravagance, he exhausted the public revenue, and covered the kingdom with disgrace. On the death of Augustus, in 1763, he was dismissed from office, and died within a few weeks. The celebrated Brühl palace still remains in Dresden; and his collections form a considerable part of the royal library.

BRUHNS, Karl Christian, a German astronomer, born at Plön, Holstein, Nov. 22, 1830. He was at first a mechanic, but became assistant to the astronomer Encke in Berlin in 1852, graduated at the university in 1856, and in 1860 became professor of astronomy at Leipzig, where he established an observatory. He is the discoverer of a number of comets. Besides many contributions to the *Astronomische Nachrichten*, he has published *Die astronomische Strahlenbrechung in ihrer historischen Entwicklung* (1861), an account of his observations from 1860 to 1865 (1866), and a biography of Encke (1869).

BRUMAIRE, The Eighteenth, the day of the year VIII. in the calendar of the French revolution corresponding to Nov. 9, 1799. On that day was begun the movement which resulted in the overthrow of the directory and the establishment of the consulate in France. Bonaparte, on his return from Egypt, found the government in power as established by the constitution of the year III. It consisted of a directory of five members (Sieyès, Barras, Ducos, Moulins, and Gohier), a senate, or council of the ancients, and the council of 500, or popular legislative branch. The republicans had a majority in the council of 500; these, with the generals Bernadotte, Jourdan, and Augereau, desired to restrain the power of the directory, and remove Barras from it. Sieyès, with a majority of the ancients, wished some less democratic organization. Barras and the other directors were anxious to retain their own power. Bonaparte and his brothers, aided by many soldiers and civilians, were in favor of any change which would throw the power into their own hands. These latter entered into a conspiracy with Sieyès and his friends for the overthrow of the government, and fixed upon the 18th Brumaire as the day for its execution. Sieyès was to manage the council of the ancients; Lucien Bonaparte was to see to the council of 500, of which he was president; Bonaparte undertook the military. At 6 o'clock in the morning of that day the council of the ancients, with the exception of the republican members who had not been notified, were convened at the Tuile-

ries, where Sieyès made a harangue upon the perils of the republic, and the reported plots of the Jacobins to reestablish the reign of terror, and induced the council to place Bonaparte in command of the military in Paris, and to transfer the sittings of both legislative bodies to St. Cloud, where they would be out of danger. Sieyès, Barras, and Ducos resigned as members of the directory, so that there was left no executive authority; but Bonaparte commanded the troops. On the next morning, Nov. 10, the two councils met at St. Cloud. The republican majority in the ancients inveighed against the trick by which they had been left out in the proceedings of the previous day. Bonaparte appeared at the bar to justify his action. He began a violent speech, lost his presence of mind, and became confused, but catching a glimpse of the grenadiers outside, he threatened the council with military violence if they should decide against him. Meanwhile in the council of 500 Lucien Bonaparte read the resignation of the three directors, amid shouts from the members of "No Cromwell! no dictator! the constitution for ever." Bonaparte now entered, accompanied by four grenadiers, and attempted to speak, but was interrupted by cries and execrations, and could utter only a few broken sentences. The members appeared to be on the point of proceeding to violence against him, when a body of soldiers rushed into the hall and bore him off. A motion was made for his outlawry; but Lucien refused to put it, left the chair, and went outside the hall, where he addressed the troops, declaring that a body of factious men in the pay of England, and armed with daggers, had set the deliberations of the representatives of the people at defiance, and that he, as president of the assembly, summoned the military to quell the disturbance. The soldiers hesitated until Lucien swore that he would stab his own brother if he attempted anything against the republic. Murat at the head of a body of grenadiers then entered the hall, and ordered the assembly to disperse. The members replied with shouts and execrations. The drums were then ordered to beat, the soldiers levelled their muskets, and the members of the council made their escape by the windows. Bonaparte had meanwhile gone to Paris, where he said that attempts had been made to stab him; and one person declared that he had received wounds intended for Bonaparte. The council of 500 was dissolved by a vote of about 50 of its members, who also in conjunction with the ancients passed a decree making Sieyès, Bonaparte, and Ducos provisional consuls, and investing them with supreme executive power. The *coup d'état* was merely begun on the 18th Brumaire, and its success was only assured on the 19th.

BRUMATH, or *Brumpt* (anc. *Brocomagus*), a town of Germany, in Alsace, on the river Zorn, 10 m. N. of Strasburg; pop. in 1871, 5,601. Here are a number of tumuli, supposed to be

the remains of a Celtic cemetery, in which have been found a hatchet, knife, ring, and other articles of Celtic origin. Near the town is the insane asylum of Stephansfeld.

BRUMMEL, *George Bryan*, a celebrated English man of fashion, born in London in June, 1778, died at Caen, France, March 29, 1840. He was educated at Eton and Oxford, where, though he displayed some skill in writing Latin verses, he was less distinguished for scholarship than for a fastidious taste in dress, which early gained for him the sobriquet of "Beau Brummel." On the death of his father in 1794 he inherited £30,000, and about the same time he became the favorite companion of the prince of Wales, who gave him a cornetcy in his regiment, and rapidly promoted him to a captaincy. Military life not being to his taste, he sold his commission and devoted himself to fashion and fine society. He set up a splendid bachelor establishment at the west end of London, and became the arbiter of taste and fashion, a position which he retained so long as the favor of the prince of Wales and his own money lasted. The former he forfeited about 1813, and the latter, replenished occasionally by gambling, gave out soon after; and in the latter part of the next year he fled from his creditors to Calais. After living there for some years on such remittances as he could obtain from his friends, he was appointed consul at Caen, where he became reduced to utter penury and died in a hospital for lunatic mendicants. See "Life of Brummel," by Capt. William Jesse (2 vols. 8vo, London, 1844; 12mo, 1854).

BRUN, *Friederike Sophie Christiane*, a German authoress, born at Gräfen-Tonna, near Gotha, June 8, 1765, died in Copenhagen, March 25, 1835. The daughter of Balthasar Münter, a German clergyman and poet, who removed to Copenhagen, she was early remarkable for her linguistic and poetical talents, and married in 1783 the wealthy Danish councillor Constantin Brun, with whom she went to St. Petersburg and to Hamburg, where she formed the acquaintance of Klopstock. She became deaf during the cold winter of 1788-'9, and subsequently travelled in various countries, and for some time in company with the princess of Dessau and the poet Matthiesson. With the latter and with the historian Johannes von Müller she spent some time in Switzerland in the house of Bonstetten, who was afterward for several years her guest in Copenhagen, and who addressed many remarkable letters to her, which have been published. After a long residence in Italy, she spent nearly the last 25 years of her life in Copenhagen, gathering round her many eminent persons. Her husband survived her hardly one year. Her early poems, edited by Matthiesson in 1795 (4th ed., Zürich, 1806), were followed by *Neue Gedichte* (Darmstadt, 1812), and *Neueste Gedichte* (Bonn, 1820). She described her travels in her *Prosaische Schriften* (4 vols.,

Zürich, 1799–1801), *Episoden* (4 vols., 1807–'18), *Römisches Leben* (2 vols., Leipzig, 1833), and in her *Briefe aus Rom*, addressed to her brother, the bishop of Seeland, edited by Böttiger (Dresden, 1816; new ed., 1820). Her last work, *Wahrheit aus Morgenträumen und Ida's ästhetische Entwicklung* (Aarau, 1824), contains a partial autobiography and an account of her daughter Ida's education.

BRUNCK, Richard François Philippe, a French philologist, born in Strasburg, Dec. 30, 1729, died June 12, 1803. He was educated in the college of the Jesuits at Paris, served in Hanover as commissary of war, and returned at the age of 30 to Strasburg, where he studied in the university till he had mastered the Greek language. As an editor he made no commentaries, but occupied himself only with the text. Persuaded that all faults in the language of the Greek poets came from the carelessness of copyists, he corrected the texts with the utmost fearlessness, regardless of manuscript readings. Holding a lucrative official position, he was enabled to issue his editions without depending on a publisher. He edited the Greek anthology, all of the tragedies of Sophocles, and several of those of Æschylus and Euripides, the Greek gnomic poets, and the works of Anacreon, Aristophanes, and Apollonius of Rhodes. His labors were interrupted by the French revolution, whose principles he espoused. He was imprisoned during the reign of terror, was twice ruined in property, and obliged to part with his books. He then turned his attention to Latin authors, and edited Virgil, Plautus, and Terence.

BRUNDISIUM. See BRINDISI.

BRUNE, Guillaume Marie Anne, a marshal of France, born at Brives-la-Gaillarde in 1763, died at Avignon, Aug. 2, 1815. He was educated at Paris for the law, but on the breaking out of the French revolution he took the side of the people, received a military appointment, and served under Dumouriez in Belgium. He was commissioned by the committee of public safety to put down the insurrection in the Gironde, which he did with the utmost rigor. He acted under Bonaparte against the revolting sections in Paris, and assisted the directory in putting down the conspiracy in the camp at Grenelle, Sept. 9, 1796. He then entered the army of Italy in the division of Masséna, distinguishing himself by his intrepidity, and became commander of the second division, hitherto commanded by Augereau. After the peace of Campo Formio he commanded the army which invaded Switzerland and captured Bonn. He was then sent to Italy, where, July 3, 1798, he forced the king of Sardinia to deliver up the citadel of Turin. In the following year he commanded in Holland, defeated the English and Russians at Bergen, and forced the duke of York to capitulate at Alkmaar, Oct. 18, 1799. After the 18th Brumaire he was appointed a member of the council of state, and sent against the royalist insur-

gents of Brittany. From 1800 to 1802 he again served in Italy, and was afterward sent as ambassador to Constantinople. In 1804 he returned to France, and was created marshal. In 1807 he received the grand cross of the legion of honor, and was sent to Hamburg as governor of the Hanseatic towns, and as commander of the reserve of the grand army. His conduct in regard to the truce with Sweden displeased Napoleon, and he was recalled in disgrace, and retired into private life. In 1814 he gave his adhesion to the acts of the senate, and received the cross of St. Louis from Louis XVIII. During the hundred days he became again a Bonapartist, and received the command of a corps of observation on the Var. After the battle of Waterloo he proclaimed King Louis XVIII., and while on his way from Toulon to Paris he was killed by a royalist mob at Avignon. His body was dragged through the streets and then thrown into the Rhône. In 1841 a monument was erected to him in his native town.

BRUNEHAUT, or **Brunchild**, queen of Austrasia, born in 534, killed in 613. The daughter of Athanagild, king of the Visigoths of Spain, she married about 567 Sigebert, king of Austrasia. Chilperic, king of Neustria, brother of Sigebert, having married Galsuinda, daughter of Athanagild, abandoned and murdered her at the instigation of his mistress Fredegonda, whom he had made his queen. Brunehaut persuaded her husband to invade Neustria. The invasion was successful, but while besieging Tournay Sigebert was assassinated in 575 by emissaries of Fredegonda. The Austrasian army dispersed, and Brunehaut fell into the hands of Chilperic, and was taken to Rouen. There she induced Meroveus, one of the sons of the Neustrian king, to marry her, and favored by Pretextatus, bishop of Rouen, effected her escape to Austrasia, then governed by her son Childebert. She succeeded in recovering her authority, and in 587 concluded with Gontran the treaty of Andelot, which fixed the limits between Austrasia and Burgundy. After the death of Childebert in 596, the nobles prevented her from ruling in the name of her grandson, Theodebert II.; but another of her grandsons, Thierry II. of Burgundy, made her mistress of his affairs. She quickly kindled a war between the two brothers. Theodebert was vanquished at Toul and at Tolbiac, and slain with his family in 612. Thierry suddenly died soon after, and Brunehaut seemed about to ascend the throne again, when she was opposed by Clothaire II., son of Fredegonda, at the head of an army of Burgundians and Austrasians. She encountered the enemy on the banks of the Aisne, but her troops refused to fight, and Brunehaut fell into the hands of the son of Fredegonda, who reproached her with having caused the death of ten kings or sons of kings, exposed her for three days to torture and to the insults of the soldiers, and then bound her by a foot and an arm to the tail of a wild horse.

Her remains were burned, and the ashes scattered to the winds. She has been diversely judged by historians, being by some accused of monstrous crimes, and extravagantly praised by others.

BRUNEL. I. Sir Mark Isambard, a civil engineer, born at Hacquerville, near Rouen, France, April 25, 1769, died in London, Dec. 12, 1849. He was the son of a farmer, was educated at Rouen, studied drawing, hydrography, and mathematical sciences, and in 1786 entered the merchant service, and made several voyages to the West Indies. In 1793, for political reasons, he fled from France to New York, where he undertook the exploration and survey of some lands on Lake Ontario for a French land company, and in 1794 commenced the survey of the Champlain canal. He sent in a design for the national capitol, which involved too much expense, and was therefore rejected; and he was much employed as an engineer and architect in New York. After a stay of some years in America, he went to England, where he invented complicated machinery for cutting the blocks used in the rigging of ships, which was secured at a large expense for the royal dockyards. He invented many other useful machines, and was constantly employed upon important architectural and engineering works. His greatest achievement was the construction of the Thames tunnel, commenced in 1825, and completed, after immense difficulties and several disasters, in 1843. In 1829 he received the cross of the French legion of honor, and in 1841 was knighted. He was a member of the royal society, and corresponding member of the French institute. II. Isambard Kingdom, an English engineer and naval architect, son of the preceding, born at Portsmouth, April 9, 1806, died Sept. 14, 1859. He was educated in the college of Henry IV. at Caen, and was resident engineer, under his father, of the Thames tunnel. He was long occupied in perfecting an engine designed by his father, the motive power of which was carbonic acid gas. This was abandoned on economical grounds, although the machinery was brought to high perfection. In 1833 he was appointed chief engineer of the Great Western railway, and he designed and constructed the numerous bridges, viaducts, and tunnels on the entire line and its branches. Among his works are the Box tunnel near Bath, and the Hungerford suspension foot bridge over the Thames, which has the longest span of any in England. He constructed the Great Western steamship, the first which regularly traversed the Atlantic, the Great Britain, the first ocean screw steamer, and the Great Eastern, the largest steamer ever built. He also took part in the floating and raising of the Conway and Britannia tubular bridges, constructed some of the most important docks on the English coast, conducted the works of the Tuscan portion of the Sardinian railway and of other foreign railways, and during the Crimean war had the entire charge of estab-

lishing and organizing the hospitals on the Dardanelles. He was elected a fellow of the royal society in 1830, and was vice president of the institution of engineers and of the society of arts, and chevalier of the legion of honor.

BRUNELLESCHI, Filippo, an Italian architect, born in Florence in 1377, died there in 1444. He was apprenticed to a goldsmith, afterward devoted himself to sculpture, and finally became the leading architect of his day in Italy. He studied the ancient architecture of Rome, and is credited with reviving the Doric, Ionic, and Corinthian orders, and settling the principles of perspective as applied to architecture. He constructed the dome of the church of Santa Maria del Fiore at Florence, the largest in diameter in the world, and designed the Pitti palace, the churches of San Spirito and San Lorenzo, and the abbey at Fiesole.

BRUNET, Jacques Charles, a French bibliographer, born in Paris, Nov. 2, 1780, died there, Nov. 16, 1867. The son of a bookseller, he early devoted himself to the study of bibliography, and made several catalogues of old libraries. His most important work is the *Manuel du libraire et de l'amateur de livres* (8 vols. 8vo, 1810). The 5th edition (7 vols. 8vo, Paris, 1860-'67) is the most complete work on bibliography ever produced. He also published *Recherches sur les éditions originales des cinq livres du roman satirique de Rabelais*, and several other works. In 1848 he received the decoration of the legion of honor.

BRUNI, Leonardo, called ARETINO, an Italian author, born in Arezzo in 1369, died in Florence, March 9, 1444. For about ten years he was secretary of the papal chancery, excepting in 1410, when he was for a short time chancellor of the Florentine republic. His career at the Vatican was terminated by his marriage in 1412, and three years later he went to Florence, where he again became chancellor. Here he completed his Latin *Historia Florentina* (Italian translation, Venice, 1473). He retained the chancellorship for 17 years, and was foremost among the celebrated scholars who met in the palace of Cosmo de' Medici. His Italian writings marked a new era in the increased polish of the language, and his Latin translations of Greek authors contributed greatly to the revival of classical learning. His history of the Goths, *De Bello Italico adversus Gothos* (Foligno and Venice, 1470-'71), is regarded as his best work. It was reprinted with Procopius, from whom it is chiefly taken, and with other histories of Gothic wars (Basel, 1531; Paris, 1584). His *Epistolæ Familiares* (most complete edition, by the abbé Mehus, Florence, 1731, with Bruni's biography and a full catalogue of his works) give valuable information respecting the literature of the 15th century. He wrote biographies in Italian of Dante and Petrarch, and of Cicero in Latin and Italian. His novel, *De Amore Guistardi et Sigismunda Filia Tancredi*, taken from Boccaccio's Decameron, has been translated into Eng-

lish in William Walter's "Amorous History of Guystarde and Sigismonde, and of thyr dolorous Deth" (London, 1532).

BRÜNINGS. I. Christian, a Dutch engineer, born at Neckarau, Germany, Nov. 8, 1736, died in Holland, May 16, 1805. He was collector of river tolls, and became in 1769 chief inspector of hydraulic works under the Netherlands government. He improved the dikes and the drainage of the lake of Haarlem, took a prominent part in preventing inundations and in improving the bed of the Rhine and other rivers, and published valuable reports relating to those enterprises. The Dutch republic proposed to erect a monument to him in the cathedral at Haarlem, and awarded a gold medal to the author of the best essay on his services. **II.** Another Dutch engineer, of the same name and family, died in Leyden, March 23, 1826. He was author of a *Dissertation sur l'angle le plus avantageux des portes d'une écluse* (1797). **III. Conrad Louis**, likewise a Dutch

engineer, born at Heidelberg in 1775, died in Nimeguen in 1816. He was employed by the Dutch government as inspector of hydraulic works, was a member of the institute, and author of various writings on hydraulic engineering and kindred subjects.

BRÜNN (Czech, *Brno*, a ford), a city of Moravia, Austria, situated on a declivity at the confluence of the Schwarza and the Zwittawa, 70 m. N. of Vienna, and 116 m. S. E. of Prague; pop. in 1870, 73,464. Fortifications separate the city from the suburbs, of which there were 20 in 1871. It was formerly defended by the castle of Spielberg, which stands on a high hill just back of the town. Since the demolition of the defences by the French in 1809, the castle has been converted into a state prison, in which were confined Silvio Pellico and other political offenders. The most notable buildings are the cathedral of St. Peter; the church of St. James, with a spire about 300 ft. high, built between 1814 and 1480;

Brünn.

the *Landhaus*, formerly an Augustinian convent; the barracks, once a Jesuit college; the Protestant church, built in 1867; the Hebrew temple; the palaces of Prince Dietrichstein and Prince Kaunitz, and the bishop's palace. A public park, the *Augarten*, was opened by Joseph II., and in the public gardens of the Franzenburg quarter are a monument to the emperor Francis I., and an obelisk commemorating the peace of 1815. The Zderad monument—one of the most ancient of Moravia—stands outside of the town. Brünn is a bishop's see, and the seat of the principal law and military courts for Moravia. There are two gymnasia, one German, the other Czech, a theological faculty, a technical academy, a normal school, a museum, a public library, botanical gardens, and institutions for the blind and for the deaf and dumb. In 1871 there were 23 literary and scientific societies, and 17 journals and periodicals. The city has repeatedly been destroyed by fire, and in 1558 the plague carried off 4,000 of the inhabitants, to whose memory a column has been raised in the great

square. The principal industry is the manufacture of wool, the most extensive establishment employing 160,000 spindles. Woollens are exported to Italy, Germany, and the United States, over 700 firms being engaged in this trade, and nearly 200 steam engines with over 4,000 horse power and an annual amount of 2,000,000 cwt. of coals are employed in it. Machinery and various other articles are also manufactured here.

BRUNN, Heinrich, a German archæologist, born at Wörlitz, Anhalt, Jan. 23, 1822. He graduated in Rome in 1843, and after extensive explorations in Italy he succeeded Emil Braun in 1856 as secretary of the archæological institute in Rome. Since 1865 he has been professor of archæology and director of the collection of coins in Munich, and since 1867 director of the collection of vases. His works include *Geschichte der griechischen Künstler* (2 vols., Stuttgart, 1853-'9), and *I rilievi delle urne etrusche* (Rome, 1870).

BRUNNEN, a village of Switzerland, in the canton and 3 m. S. W. of Schwytz, near the

mouth of the Muotta, on the lake of Lucerne; pop. in 1870, 1,774. It is memorable as the spot where the deputies of the three original cantons, Schwytz, Uri, and Unterwalden, shortly after the battle of Morgarten, laid the basis of the Swiss republic, in December, 1315.

BRUNNER, or **Brunn**, **Johann Conrad**, a German anatomist, born near Schaffhausen, Switzerland, Jan. 16, 1653, died at Mannheim, Oct. 2, 1727. He was professor in the university of Heidelberg, afterward physician to the elector palatine, and was ennobled under the name of Bruno von Hammerstein. He made many original researches, particularly on the pancreas and on the glandular follicles of the small intestine. Those of the duodenum, first accurately described by him, are still known under the name of Brunner's glands.

BRUNNER, **Sebastian**, a German ultramontane author, born in Vienna, Dec. 10, 1814. He was ordained in 1838, and, after holding minor clerical offices, was appointed in 1853 chaplain of the university of Vienna, where he had studied theology. His denunciation of liberal tendencies proved congenial to Prince Metternich, who employed him on various occasions. In 1848 he founded the *Wiener Kirchenzeitung*. His *Nebelfungen-Lied*, a satire against Hegelianism, passed through four editions between 1845 and 1857. He described his travels in humorous sketches, and in 1853 published his autobiography under the title of *Woher? Wohin?* (2 vols.). His *Clemens Maria Hofbauer und seine Zeit* (1858), and *Die Kunstgenossen der Klostergeschichte*, are among his most valuable productions, on account of the ecclesiastical and artistic data which they contain. He began in 1863 to publish a complete edition of his prose and poetical works, to consist of 20 volumes. Among his miscellaneous theological publications, one is directed against Renan's "Life of Christ" (1864).

BRUNNOW. **I. Ernest Georg von**, a German novelist and advocate of homœopathy, born in Dresden, April 6, 1796, died there, May 4, 1845. He was a lawyer and judicial officer at Dresden, but having in 1818 been cured of a disease of the eyes by Hahnemann's treatment, he resigned his position in 1822 and devoted himself to medicine and the dissemination of the principles of homœopathy. He took a prominent part in the foundation of a homœopathic association in Germany, and translated Hahnemann's *Organon der Heilkunde* into French, and, in conjunction with Stapf and Gross, his *Reine Arzneimittellehre* into Latin. In 1844 he wrote *Ein Blick auf Hahnemann und seine Homœopathie*. He was also the author of some lyrical poems and novels. **II. Philipp**, count, a Russian diplomatist, brother of the preceding, born in Dresden, Aug. 31, 1797. He entered the Russian service in 1818, became ambassador at London in 1840, and remained there till after the outbreak of the Crimean war. In 1855 he was sent to Frankfort as envoy to the German diet, the emperor Nicholas being displeased

with his having deceived him in regard to the peaceful disposition of the English cabinet. In the negotiation of the treaty of Paris, 1856, he assisted as one of the Russian plenipotentiaries, and in September he became ambassador at Berlin, continuing till March, 1858, when he resumed his former post in London. In 1864 he strove to promote the interests of Denmark at the conferences in London, and in 1871 he attended the conference for the denaturalization of the Black sea. In the same year he was promoted to the rank of count, after more than 50 years' diplomatic service.

BRUNO THE GREAT, archbishop of Cologne and duke of Lorraine, son of Henry I., emperor of Germany, born in 925, died at Rheims, Oct. 11, 965. He was raised to his dignities by his brother, the emperor Otho I., whom he accompanied on his first expedition to Italy, and was equally distinguished for learning, eloquence, and charity. There are attributed to him commentaries on the Gospels and the Pentateuch, and several lives of saints.

BRUNO, **Saint. I.** The apostle to the Prussians, born of a noble Saxon family at Querfurt in 970, killed in 1008. He was an Italian Benedictine, succeeded St. Adalbert in his missionary labors, was active in Poland and among the Petchenegs, became chaplain of the emperor Henry II., and was assassinated by the pagans on the confines of Lithuania. **II.** Founder of the order of Carthusians, born of a noble family at Cologne about 1040, died at La Torre in Calabria in 1101. Refusing the metropolitan see of Rheims, he forsook the world for the practice of asceticism in the mountain wilds between France and Italy. The order which he founded derives its name from his abode, a desert place called Charteuse, near Grenoble, where in 1084 he gathered a small community and established rules of a severe austerity. He was invited to Rome in 1089 by Pope Urban II., who had formerly been his disciple, refused the ecclesiastical dignities that were offered him, died in a monastery which he had founded, and was canonized in 1514.

BRUNO, **Giordano**, an Italian philosopher, born at Nola, near Naples, about the middle of the 16th century, burnt at the stake in Rome, Feb. 17, 1600. He entered the Dominican order at an early age, but, becoming skeptical, was forced to leave it, and fled to Geneva in 1580. His ideas were no more acceptable to the Calvinists than to the Catholics, and after two years he went to Paris, where he gained some celebrity by writing a satirical comedy, *Il candelajo*, and delivering lectures on the *Ars Magna* of Raymond Lully. His attacks on the philosophy of Aristotle aroused much hostility among the scholars and clergy of Paris, and in 1583 he went to England, where he enjoyed the friendship of Sir Philip Sidney, and wrote some of his most important philosophical works. In 1585 he returned to Paris, and the next year went to Germany. After a brief

stay at Marburg, he settled at the university of Wittenberg as a lecturer on philosophy and mathematics. He remained there only two years, after which he went from one university to another, lecturing in turn at Prague, at Helmstedt, and at Frankfort, until, in 1592, he ventured to return to Italy. During a visit to Venice, he was arrested by the inquisition on May 23, and in 1593 was delivered to the Roman authorities. In Rome he was imprisoned for seven years, tried, degraded, excommunicated, and finally handed over to the civil power, by which he was sentenced to death. (See Berti, *Vita di Giordano Bruno*, Florence, 1868.) He was a man of great mental activity and boldness of thought. Montaigne excepted, there is no philosopher of the 16th century who has been so frequently a subject of research and comment by modern scholars as Giordano Bruno. Descartes borrowed largely from him, and Spinoza's system would appear almost like Bruno's, refined in the logical crucible of Descartes. Even with some philosophers of the present century Bruno has been a favorite. One of the profoundest works of Schelling bears the name of Bruno on its title ("Bruno, or the Divine and the Natural Principle of Things"), and this once more directed the general attention of scholars to Bruno's works, which had become extremely rare. They have been republished since then, those in Italian by Wagner (*Opere di Giordano Bruno*, 2 vols., Leipsic, 1830), those in Latin (*Jordani Bruni Nolani Scripta quæ latine redegit omnia*), by Gfrörer, in his *Corpus Philosophorum* (Stuttgart, 1834). Of his satires the best are the *Spaccio della bestia trionfante* ("Expulsion of the Triumphant Beast"), and the *Cabala del cavallo Pegaseo coll' aggiunta del asino Cillenico*, a satirical eulogy on ignorance. The *Cena delle Ceneri* ("Table Talk on Ash Wednesday") is a spirited dialogue in defence of the Copernican theory. Those works in which he developed his philosophical views are the essays *Della causa, principio ed uno*, *Dell' infinito universo e mondi*, and *De Monade, Numero et Figura*.—In his system there is but one fundamental principle, one substance, whose existence is real and original. This eternal and infinite being produces by contraction or expansion innumerable apparitions, whose existence is but secondary, merely a shadow of that of the original being. God and the universe are identical; the universe is infinite. Every being or thing (*ens*) has, besides the innermost principle of its existence, a cause of existence. While the former is the immanent condition, the latter is the immediate source of existence. The original cause is the universal intellect which shapes and moulds matter into individual forms. In the harmonious perfection of the universe all possible forms would obtain real existence in all portions of matter. Every form being the result of an intellectual action, and matter being conceivable only under some form or other, it follows

that everything is living or has its soul, which is its form. The substance of all existing beings is one and the same; it is only the forms brought forth by the intellectual activity of the original substance which show differences of appearance. The universe, considered as a whole, is a unit, infinite, immovable, the absolute identity of possibility, reality, and action. This grand unit of all substances, of which all beings and things are only secondary manifestations, is God; God is the monad of the monads. Man, as an intermediate being between time and eternity, belongs to both spheres at the same time, the spiritual and the sensual; but his principal aim is the mind and intellect. The human mind is an integral portion of the divine substance; the perception of the supreme truth, the volition of the supreme good, are its goal. From the narrow sphere of common life, man ought to rise to a conception of his relation to the universe, and of the affinity of his spiritual being to the universal intellect.

BRUNSWICK. I. A S. E. county of Virginia, bordering on North Carolina, watered by the Nottoway, Roanoke, and Meherrin rivers; area, 600 sq. m.; pop. in 1870, 18,427, of whom 8,902 were colored. A large portion of the land is exhausted by the tobacco culture, but has been improved by the use of guano. The chief productions in 1870 were 44,309 bushels of wheat, 166,892 of Indian corn, 68,283 of oats, and 1,121,480 lbs. of tobacco. There were 859 horses, 1,540 milch cows, 3,917 other cattle, 2,582 sheep, and 7,256 swine. Capital, Lawrenceville. II. A S. E. county of North Carolina, bordering on South Carolina, washed by the Atlantic, and drained by Cape Fear and Waccamaw rivers; area, about 1,100 sq. m.; pop. in 1870, 7,754, of whom 3,306 were colored. The surface is level, and much of it swampy. The soil is poor and sandy, but capable of producing rice and cotton to some extent. Pine timber, tar, and rosin are exported in considerable quantities, and the cypress and juniper grow in the swamps. The Wilmington and Weldon, and the Wilmington, Columbia, and Augusta railroads pass through the county. The chief productions in 1870 were 56,211 bushels of Indian corn, 129,168 of sweet potatoes, 119 bales of cotton, and 748,418 lbs. of rice. There were 372 horses, 2,777 milch cows, 4,295 other cattle, 3,555 sheep, and 10,485 swine. Capital, Smithville.

BRUNSWICK. I. A town and village of Cumberland co., Me., on the right bank of the Androscoggin river, at the head of tide water, 30 m. by railroad N. N. E. of Portland; pop. of the town in 1870, 4,687; of the village, 1,449. A bridge over the falls unites it with Topsham, and another bridge is used by the Kennebec and Portland railroad. The Androscoggin railroad connects it with Augusta, 30 m., and the Bath branch with Bath, 9 m. distant. The falls of the Androscoggin furnish ample water power. The town contains a

cotton mill, two flour mills, a bleachery, a tannery, and many other factories. It is the seat of Bowdoin college, and has 11 churches, 3 national banks, and a weekly and a bi-weekly paper. Much capital is invested in shipping.

II. A town, port of entry, and the capital of Glynn co., Ga., situated on a bluff on Turtle river, 70 m. S. S. W. of Savannah; pop. in 1870, 2,848. It has a spacious and secure harbor, with 13 ft. of water over the bar at low tide, and a lighthouse on St. Simon's island, 8 m. below. The entrance to St. Simon's sound, through which the Turtle river enters the Atlantic, is about 10 m. W. of the town. For the year ending June 30, 1871, the value of imports from foreign countries was \$291,413; exports, \$380,116. A weekly newspaper is published here. The town is the terminus of the Macon and Brunswick, and the Brunswick and Albany railroads.

BRUNSWICK (Ger. *Braunschweig*). **I.** A duchy of N. W. Germany, composed of three large portions, separated from each other chiefly by Prussian territory: 1, the principality of Wolfenbüttel, embracing the circles of Brunswick, Wolfenbüttel, and Helmstedt; 2, the district of the Hartz and the Weser, embracing the circles of Gandersheim and Holzminden; 3, the principality of Blankenburg, on the lower Hartz. Besides these three large portions, there are five small isolated districts. Its area and population in 1871 were as follows:

CIRCLES.	Area, square miles.	Population.
1. Brunswick.....	210	90,845
2. Wolfenbüttel.....	295	60,739
3. Helmstedt.....	308	53,705
4. Gandersheim.....	212	42,822
5. Holzminden.....	222	41,651
6. Blankenburg.....	158	22,523
Total.....	1,425	311,715

Of the inhabitants 97·96 per cent. are Protestants, 1·68 Catholics, and 0·36 Jews. The Protestants, with the exception of 1,700 Reformed, are Lutherans. The general character of the surface is hilly, and in the mountainous districts the climate is severe and the harvest late. About 33 per cent. of the land is arable; 27 per cent. consists of meadows, and 32 of woodland. The largest rivers are the Ocker, Leine, and Weser, the last of which drains the greater part of the duchy and has many affluents. Brunswick may be divided into the mining districts, which lie chiefly among the Hartz mountains, and the agricultural regions, which comprise nearly all the rest of the country. Grain, fruit, tobacco, flax, cattle, and horses are raised in the latter, while the former are rich in gold, silver, copper, lead, iron, sulphur, and coal. The mines, in some of which Hanover has a joint interest, are not now so productive as in former times, but are still of high value. Other minerals, such as marble, alabaster, limestone, gypsum, potter's clay, asbestos, asphaltum, jasper, and agate, are found in various

localities. Salt is obtained in abundance. The manufactures are inconsiderable. Spinning is a favorite occupation, and there are several camlet manufactories, dye houses, paper, oil, and saw mills, breweries, iron works, and manufactories of lacquered wares and porcelain. The advantages of railway communication with Hanover, Magdeburg, and Neustadt have given to trade a magnitude scarcely to be expected from the geographical position of the country. The aggregate length of railways in 1871 was 181 m. The university of Helmstedt was suppressed in 1809, but there are 5 gymnasia, a polytechnic school, a theological seminary, 2 normal, 21 Latin, and 369 common schools, and a library at Wolfenbüttel, of considerable repute.—The form of government is a limited hereditary monarchy, the supreme power being vested in the duke and a legislative body of one chamber, consisting of 46 members, of whom 21 are chosen from the owners of large landed estates and the highest taxpayers, 10 from the towns, 12 from the rural districts, and 3 representatives of the church. They are elected for six years, one half going out of office every three years. They assemble triennially on convocation by the duke, but in certain cases may meet without his authority. The duchy holds the 11th place among the states of the German empire, has two votes in the federal council, and elects one delegate to the Reichstag. To the army of the empire it contributes a regiment of infantry, a regiment of hussars, a battery of four pieces of ordnance, and two landwehr battalions. The public debt in 1871 was 23,765,768 thalers, including 19,670,700 thalers for railways; and the budget for the three years 1870-'72 presented an aggregate revenue of 7,196,400 thalers, and the same aggregate amount of expenditure.

II. A city, capital of the above described duchy, situated on the Ocker, 32 m. E. S. E. of Hanover, and connected by railways with the other cities of Germany; pop. in 1871, 57,882. It is said to have been founded in the 9th century, by Bruno, second duke of Saxony, was enlarged by Henry the Lion, ranked in the 13th century among the first cities of the Hanseatic league, and, although much less important than in former times, continues to be one of the most active cities of N. W. Germany. The annual fairs held here are, after those of Leipsic and the two Frankforts, the most animated in Germany. The pork sausages of Brunswick (*Braunschweiger Wurst*), and its beer, have acquired great celebrity; the latter is known under the name of *Braunschweiger Mumme*, after Christian Mumme, who was the first to prepare it in 1492. The trade in this beer extended in former years to India. The book trade is of great importance. Brunswick is the seat of a bank and of several banking establishments. The appearance of the town is antiquated, but there are several handsome streets and promenades. The new ducal palace is a magnificent building, with beautiful pleasure grounds. The most interesting monuments of

the ancient cathedral of St. Blaise are the tombs of the ducal family. There are 10 churches and a synagogue. The Gewandhaus, in the old

Gewandhaus.

German style of architecture, and the council house, an elaborate Gothic structure, are among the most picturesque buildings. The museum

Council House.

in the arsenal contains a gallery of valuable paintings. The most prominent institution of learning, the *Collegium Carolinum*, which was

founded in 1745, was in 1861 converted into a polytechnic school. The city has also a Lutheran gymnasium, a *Realgymnasium*, an institution for the blind, and one for the deaf and mute. Monuments have been erected to the two dukes of Brunswick who fell at Jena and at Quatre Bras; to the memory of Schill and his companions, 14 of whom were shot here; and to Lessing, who died here. Reitschel's statue in honor of Lessing was erected in 1853. The most extensive of the many charitable and sanitary institutions is a great asylum which accommodates 250 orphans.

BRUNSWICK, House of, one of the oldest families in Germany, a branch of which occupies the throne of Great Britain. The Brunswick territory, then forming a part of Saxony, was by Charlemagne united to the Frankish empire, and with the other Saxon provinces was governed successively by the princes of the house of Saxe, Billung, Supplenburg, and Guelph. The Guelph house, of mixed Italian and German origin, obtained, in the person of Otho the Young, in 1235, the city of Brunswick as a fief of the empire, which with its dependencies was then first erected into a duchy. The two sons of Otho, Albert and John, reigned in common from 1252 to 1267, and then divided the paternal inheritance. John received the city of Hanover and the duchy of Lüneburg; Albert, the duchy of Brunswick, the Hartz, and the district of the Weser; the city of Brunswick remained common property. John and Albert thus founded the elder branches of Lüneburg and Wolfenbüttel. The former of these became extinct in 1369, and its possessions reverted to the latter. Albert left three sons, Henry, Albert the Fat, and William, who divided the inheritance, and founded the three lines of Grubenhagen, Göttingen, and Wolfenbüttel. The first of these divided into two branches in 1361, both of which became extinct in 1596, and their possessions returned to the Wolfenbüttel line. The Göttingen branch became extinct in 1463, and its possessions were transferred to the duke of Kalenberg. From the Wolfenbüttel branch sprang in 1409 the two new branches of Lüneburg and Wolfenbüttel-Kalenberg, the latter of which in 1634 transferred its possessions to the duke of Brunswick-Lüneburg-Dannenberg, a descendant of the Lüneburg branch. The Lüneburg branch had divided in 1569, and had another offshoot in the family of Brunswick-Lüneburg, which has furnished the electoral and royal dynasty of Lüneburg-Hanover. Henry, duke of Brunswick-Lüneburg-Dannenberg, who died in 1598, was the founder of the present dynasty of Brunswick. His line was divided in 1666 into the branches of Brunswick-Wolfenbüttel and Brunswick-Bevern, the former of which became extinct in 1735, the possessions passing to the latter, which has retained them undivided from that time to the present. Among the queens belonging to this family have been Sophia Dorothea, wife of

George I., king of England; Amelia Elizabeth Caroline, the wife of George IV.; and Sophia Charlotte and Sophia Dorothea, queens of Prussia, the latter the mother of Frederick the Great. The first wife of Leopold I. of Belgium was Charlotte Augusta, daughter of Queen Caroline of England. The following are the most prominent members of the family. **I. Ernest**, duke of Brunswick-Lüneburg, born June 26, 1497, died June 11, 1546. He embraced the doctrines of Luther, signed the confession of Augsburg, and adhered to the Smalcaldic league. His eulogy was pronounced by Melancthon.

II. Christian, duke of Brunswick-Lüneburg, born Sept. 10, 1599, died June 9, 1626. In the thirty years' war he enthusiastically espoused the cause of the elector palatine Frederick V., elected king of Bohemia. After the flight of that prince from Prague in 1620 he ravaged Hesse and the electorate of Mentz, was defeated by the imperialists on the Main, entered the service of the Dutch in 1622, and forced the Spaniards to raise the siege of Berg-op-Zoom, but was afterward again defeated by Tilly. His motto was, "Friend of God, enemy of priests." **III. Ernest Augustus**, duke of Brunswick-Lüneburg, and first elector of Hanover, born Nov. 20, 1629, died Jan. 28, 1698. He became bishop of Osnabrück in 1662, travelled extensively, and was distinguished as a general and diplomatist. He served the emperor Leopold I. in his war against France, for which he was rewarded with the electoral dignity in 1692. By his marriage with Sophia, daughter of the elector palatine Frederick V., and granddaughter of James I., king of England, his house obtained a right to the throne of England. His son George Louis became king of England in 1714 under the name of George I. **IV. Ferdinand**, duke of Brunswick, a general in the seven years' war, born at Brunswick, Jan. 11, 1721, died July 3, 1792. He entered the Prussian army in 1740, assisted at the capture of Prague, obtained in 1757 the command of the Anglo-Hanoverian army in Westphalia, defeated the French at Orefeld and at Minden, and in 1763, by reason of a disagreement with Frederick the Great, retired to his castle at Vechelde, where he occupied himself with freemasonry and with the encouragement of the fine arts.

V. Charles William Ferdinand, duke of Brunswick, a Prussian general, born at Wolfenbüttel, Oct. 9, 1735, died near Altona, Nov. 10, 1806. His services during the seven years' war were celebrated by Frederick the Great in a poem. He participated in the battle of Orefeld in 1758, and in 1787 marched into Holland to restore the hereditary stadtholder. After the treaty of Pilnitz he was intrusted with the command of the allied armies against France. He published at Coblenz, July 15, 1792, his famous manifesto, threatening to march directly upon Paris, cut off supplies, and reduce that city by famine. He penetrated into Champagne, but was obliged after the engagement at Valmy to conclude an armistice with Dumouriez. In

1793 he commanded the army of the Rhine, reappeared in 1806, after an interval of retirement, at the head of the Prussian army, and commanded at the battle of Auerstädt, where he was mortally wounded. **VI. Frederick William**, duke of Brunswick, fourth son of the preceding, a Prussian general in the Napoleonic wars, born Oct. 9, 1771, fell in the battle of Quatre-Bras, June 16, 1815. He became duke of Oels and Bernstadt in 1786, and succeeded to the dukedom of Brunswick after the death of his eldest brother and the abdication of the two others in 1806. At the head of a body of hussars, which he raised in Bohemia, he entered upon the campaign of 1809, was obliged by Rewbell to retreat, and to take refuge with his army in England, where he was received with distinction. He returned to his country in 1813, and fell two days before the battle of Waterloo. **VII. Charles Frederick Augustus William**, duke of Brunswick, son of the preceding, born at Brunswick, Oct. 30, 1804, died in Geneva, Aug. 19, 1873. His education was very imperfect; he paid but little attention to public affairs; and after his assumption of power upon attaining his majority in 1823, his rule was so negligent and arbitrary that he was expelled by an insurrection, Sept. 7, 1830, declared incapable of governing by the Germanic diet, Dec. 2, and formally deposed by a family council, April 25, 1831, in favor of his younger brother William (Augustus Louis William Maximilian Frederick, born April 25, 1806), who had previously governed in his name. He afterward resided mostly in Paris and London, making himself conspicuous by his eccentricities, his revolutionary manifestoes, and especially his extraordinary precautions for the protection of a valuable collection of jewels.

BRUNSWICK GREEN, a compound of chloride and oxide of copper and water, prepared by oxidizing metallic copper in the air, by sprinkling it with a mixture of sulphate of copper, common salt, and water. It is also generated by the corrosion of copper in sea water. Its composition, as given by Berzelius, is one equivalent of the chloride and three equivalents of the oxide of copper. An artificial bicarbonate of copper, or mountain green, is also sometimes called Brunswick green. They are both used as pigments.

BRUNTON, Mary Balfour, an English novelist, born in the island of Barra, in the Orkneys, Nov. 1, 1778, died in Edinburgh, Dec. 19, 1818. At the age of 20 she married the Rev. Alexander Brunton, a minister of the Scottish church, and subsequently professor of oriental languages in the university of Edinburgh. In 1811 she published a novel, "Self-Control," which obtained immediate popularity from its moral tone, as well as its literary merits. This was followed by "Discipline" (1814), which was equally successful. Some months after her death her husband published a volume of her "Remains," with a memoir of her life and extracts from her correspondence.

BRUSA, or **Broussa** (anc. *Prusa* or *Prusias ad Olympum*, from being situated at the foot of the Bithynian Olympus), a city of Asia Minor, capital of the Turkish vilayet of Khodavendighiar, 57 m. S. of Constantinople, and 15 m. S. E. of the sea of Marmora; pop. in 1855, 102,907, of whom 64,087 were Mohammedans, 27,173 Greeks, 9,243 Armenians, and 2,404 Jews. It is the residence of a Greek and an Armenian archbishop, and has an extensive trade with Aleppo and Smyrna, chiefly in carpets, cloths, silks, and satins, which are largely manufactured in the town. In the vicinity

are noted thermal springs. An earthquake, Feb. 28, 1855, destroyed the greater part of the town, ruined 80 of the finest mosques, and killed 100 of the inhabitants. In antiquity Prusa was the capital of Bithynia, deriving its name from Prusias, one of the early Bithynian kings. Under the Romans it was the residence of Pliny the Younger and of other Roman governors. Wrested from the hands of the Greek emperors by Orkhan, the son of the founder of the Ottoman dynasty, it became the seat of the new empire, till Amurath I. removed the seat of government to

Brusa.
